6. Perform the required quality control procedures.
RATIONALE: To ensure that the machine is working as expected.
7. Insert the strip into the meter, following the manufacturer's instructions.
8. Perform a capillary puncture, following the steps outlined in Procedure 48-3.
9. Touch the drop of blood to the reagent strip, allowing it to be taken up by the strip.
10. Read the digital result after the required amount of time.
11. Discard the reagent strip and used supplies according to OSHA standards.
12. Record the time of the test and the result on the laboratory slip.
13. Disinfect the equipment and area.
14. Remove the gloves and wash your hands.
15. Document the test results in the patient's chart/progress note. Record the quality control tests in the quality control log.

PROCEDURE 48-7 Performing a Rapid Infectious Mononucleosis Test

WORK // DOC

Procedure Goal: To determine the presence of antibodies associated with infectious mononucleosis using whole blood, serum, or plasma

OSHA Guidelines:

Materials: Infectious mononucleosis test kit, patient blood specimen, and a watch or timer, patient's chart/progress note, and/or laboratory report form, quality control log

Method:

1. Review the laboratory requisition form and gather the necessary supplies.

2. Greet the patient, confirm the patient's identity, and introduce yourself.
3. Explain the procedure.
4. Wash your hands and don required PPE.
5. Obtain a specimen of the patient's blood using appropriate venipuncture technique.
6. Process the blood specimen to obtain whole blood, plasma, or serum as required by the testing procedure.
7. Open the test kit and check the expiration date.
8. Run the recommended controls according to the manufacturer's instructions and record in the quality control log.
RATIONALE: To ensure that the test is working correctly.
9. Place the required amount of blood, serum, or plasma onto the testing device, following the manufacturer's instructions.
10. Add testing reagent or reagents to the testing device, according to the manufacturer's instructions.
11. Wait the required amount of time. Do not go over the recommended time.

RATIONALE: Reading the test too early can result in a false negative, and reading the test too long after the recommended time can result in a false positive.

12. Read the results and record them in the patient's chart/progress note and/or the laboratory report form.

13. Discard the testing supplies according to OSHA regulations.

14. Disinfect the work area.

15. Remove your PPE and wash your hands.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
48.1 Discuss the role of the medical assistant when collecting, processing, and testing blood specimens.	As a medical assistant, you will collect and process blood specimens for examination, make sure the test results are handled efficiently and accurately, and complete the necessary paperwork before and after each test.
48.2 Describe the steps and equipment needed to collect a blood specimen.	Preparation for collecting blood specimens includes reading and interpreting the test order and collecting the necessary equipment for the type of specimen to be collected. General equipment includes alcohol wipes, sterile gauze, and adhesive bandages. For venipuncture, you will need a tourniquet, specimen-collection tubes, and a needle system such as Vacutainer®. For capillary puncture, you will need a puncture device and capillary tubes.
48.3 Summarize ways to communicate with patients and respond to their needs when collecting blood.	Patients are often concerned about pain, bruising, and scarring when having blood drawn. They are sometimes afraid they may have a serious disease, especially if large amounts of blood are drawn. Good communication by the medical assistant is the key to easing these fears. There are always patients who will have special needs, including children, the elderly, patients who have bleeding disorders, and difficult patients. Each patient will present a special set of challenges and should be treated with the utmost care and concern.
48.4 Carry out the procedure for collecting a blood specimen.	Blood is collected by one of two means: venipuncture and capillary puncture. Venipuncture is the process of obtaining a blood specimen from a vein. Capillary puncture is the process of obtaining blood from a superficial skin puncture. When collecting blood specimens, it is essential that you confirm the patient's identity before the specimen is collected, cleanse the skin prior to collection, follow standard precautions, collect the specimen needed in the appropriate tube or container, and ensure the patient's safety at all times.
48.5 Carry out the procedure for performing blood tests.	Hematologic, chemical, and serologic tests require special care when performing them. The medical assistant should review the manufacturer's instructions carefully for important information about correctly performing each test.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall Sylvia Gonzales from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. What blood tube(s) would you fill to collect a specimen for the CBC and lytes? Which tube would you fill first?
2. Compare a fasting blood sugar test to a hemoglobin A1C test.
3. What steps will you take to perform a dermal puncture?
4. If Sylvia tells you that she ate breakfast before coming in for the test, what should you do?

EXAM PREPARATION QUESTIONS

1. (LO 48.4) The small depression inside the bend of the elbow is the
 - a. Cephalic space
 - b. Median cubital depression
 - c. Basillic area
 - d. Axillary depression
 - e. Antecubital fossa
2. (LO 48.5) The rupturing of erythrocytes is known as
 - a. Hemolysis
 - b. Hemoglobin
 - c. Hematopoiesis
 - d. Hemorrhage
 - e. Erythrocytosis
3. (LO 48.2) A lavender-topped venipuncture collection tube contains which of the following?
 - a. Sodium citrate
 - b. Heparin
 - c. EDTA
 - d. SST
 - e. Potassium oxalate
4. (LO 48.5) What is contained within the buffy coat?
 - a. Plasma
 - b. White blood cells
 - c. Red blood cells
 - d. Fibrinogen
 - e. Serum
5. (LO 48.5) Which of the following tests gives the licensed practitioner an overall picture of a patient's compliance with diabetes diet and treatment?
 - a. Blood glucose
 - b. Hemoglobin A1C
 - c. Cholesterol
 - d. CBC
 - e. Fasting blood sugar
6. (LO 48.2) A flat, broad length of vinyl or rubber used to apply pressure to the forearm so that the underlying veins stick out is a
 - a. Drain
 - b. Velcro® closure
 - c. Butterfly
 - d. Tubing
 - e. Tourniquet
7. (LO 48.3) A patient arrives at the clinic for a FBS. He tells you he just ate his breakfast. What is your best course of action?
 - a. Draw the blood immediately
 - b. Tell the patient to come back later in the day
 - c. Ask another medical assistant to assist you with the test
 - d. Do not draw a fasting blood sugar, since the patient is not fasting
 - e. Encourage the patient to drink a lot of water before you draw the blood
8. (LO 48.5) Which of the following keeps blood from clotting?
 - a. Serum separator
 - b. Anticoagulant
 - c. Antibody
 - d. Silicone
 - e. Clot activator
9. (LO 48.5) Which of the following tests is *most* likely used to test for inflammation, infectious diseases, and malignant neoplasms?
 - a. Erythrocyte sedimentation rate
 - b. RBC count
 - c. AST
 - d. Amylase
 - e. FBS
10. (LO 48.2) Which of the following represents the correct "order of draw" from first venipuncture collection tube to last?
 - a. Gold, light blue, green, lavender, yellow
 - b. Light blue, green, gold, yellow, lavender
 - c. Yellow, light blue, gold, green, lavender
 - d. Green, yellow, lavender, gold, light blue
 - e. Yellow, lavender, gold, light blue, green

hoping to get this medication refilled. The physician wants to evaluate his congestive heart failure. He orders an ECG and a stress echocardiogram. The patient has not previously had a stress echocardiogram and you need to explain it to him before the test begins.

Keep John in mind as you study this chapter. There will be questions at the end of the chapter

based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 49, you will be able to:

- 49.1** Discuss the medical assistant's role in electrocardiography and pulmonary function testing.
- 49.2** Explain the basic principles of electrocardiography and how it relates to the conduction system of the heart.
- 49.3** Identify the components of an electrocardiograph and what each does.
- 49.4** Carry out the steps necessary to obtain an ECG.
- 49.5** Summarize exercise electrocardiography and echocardiography.
- 49.6** Explain the procedure of Holter monitoring.
- 49.7** Carry out the various types of pulmonary function tests.
- 49.8** Describe the procedure for performing pulse oximetry testing.

KEY TERMS

- | | |
|-----------------------------|----------------------------------|
| artifact | hypoxemia |
| calibration syringe | lead |
| cardiac cycle | peak expiratory flow rate (PEFR) |
| deflection | polarity |
| depolarization | pulmonary function test (PFT) |
| dysrhythmia | repolarization |
| echocardiography | rhythm strip |
| electrocardiogram (ECG) | sleep apnea |
| electrocardiograph | spirometer |
| electrocardiography | spirometry |
| electrode | stress test |
| forced vital capacity (FVC) | |
| Holter monitor | |

- I.C.9** Analyze pathology for each body system including:
(a) diagnostic measures
(b) treatment modalities
- I.P.2** Perform:
(a) electrocardiography
(d) pulmonary function testing
- I.P.3** Perform patient screening using established protocols
- I.A.3** Show awareness of a patient's concerns related to the procedure being performed

2. Anatomy and Physiology

- c. Identify diagnostic and treatment modalities as they relate to each body system

9. Clinical Procedures

- a. Practice standard precautions and perform disinfection/sterilization techniques
- e. Perform specialty procedures including but not limited to minor surgery, cardiac, respiratory, OB-GYN, neurological, gastroenterology

► Introduction

It is not uncommon for patients to have cardiovascular or respiratory problems when they consult their licensed practitioner. As a medical assistant, you may be responsible for performing screening and/or diagnostic testing in the physician's office. To correctly perform cardiac and respiratory testing, you need to review the anatomy and physiology of the heart and the respiratory system. (Refer to the chapters *The Cardiovascular System* and *The Respiratory System*.) This chapter introduces you to the electrocardiograph instrument and how to administer an electrocardiogram. You also will learn how to apply electrocardiograph electrodes and wires, operate the instrument, and troubleshoot problems that can occur while recording the heart's electrical activity. Because many physicians perform more complex cardiac diagnostic testing, you also will learn about Holter monitors and stress testing. Pulmonary function testing is a procedure performed in physicians' offices, and this chapter introduces you to the basics of performing respiratory procedures such as spirometry, peak flow, and pulse oximetry.

► The Medical Assistant's Role in Electrocardiography and Pulmonary Function Testing

LO 49.1

Electrocardiography and pulmonary function testing are two procedures you may be required to perform in a medical office. **Electrocardiography** is the process by which a graphic pattern is created from the electrical impulses generated within the heart as it pumps. It is often performed to evaluate symptoms of heart disease, to detect abnormal heart rhythms, to evaluate a patient's progress after a myocardial infarction (MI), or to check the effectiveness or side effects of certain medications. Electrocardiography is sometimes performed as part of a general examination.

Pulmonary function tests (PFTs) measure and evaluate a patient's lung capacity and volume. Such tests are commonly performed when a person suffers from shortness of breath, but

they also may be performed as part of a general examination. Pulmonary function tests can help detect and diagnose pulmonary problems. They also are used to monitor certain respiratory disorders and to evaluate the effectiveness of treatment.

► Basic Principles of Electrocardiography

LO 49.2

Weak or strong, fast or slow, each heartbeat produces an electrical current that can be measured with an electrocardiograph. Measuring and recording each heartbeat gives the doctor a "picture" of how the heart's electrical system is working. Understanding the basics of the conduction system and how it appears on an ECG tracing is essential when performing electrocardiography.

Conduction and Electrocardiography

Electrocardiography records the transmission, magnitude, and duration of the heart's various electrical impulses. Before you can understand how electrocardiography works, you must understand **polarity**, the condition of having two separate poles, one of which is positive and the other negative. Similar to a bar magnet with one end north and one south, a resting cardiac cell is polarized; that is, it has a negative charge inside and a positive charge outside. When the cardiac cell loses its polarity (a natural occurrence), depolarization occurs. **Depolarization** is the electrical impulse that initiates a chain reaction resulting in contraction. This wave of depolarization flows from the SA node to the ventricles and can be detected by **electrodes**, or electrical impulse sensors, placed on specific areas on the surface of the body. During electrocardiography, electrodes detect and record the heart's electrical activity, including disturbances or disruptions in its rhythm.

Depolarization is always followed by a period of electrical recovery called **repolarization**, when polarity is restored. Following repolarization, the heart returns to a resting, polarized state. The electrical cycle is then repeated, leading to another **cardiac cycle**—sequence of contraction and relaxation. See Table 49-1 and Figure 49-1.

- 1 The heartbeat originates in the sinoatrial (SA) node; it travels across the wall of the atrium through the internodal pathways to the atrioventricular (AV) node and Bachmann's bundle to the left atrium.
- 2 The impulse passes through the AV node into the bundle of His (AV bundle) to the interventricular septum.
- 3 The impulse is divided between the right and left bundle branches and travels to the apex of the heart through the interventricular septum via the bundle branches.
- 4 The Purkinje fibers carry the impulse throughout the right and left ventricles, causing them to contract.

FIGURE 49-1 Conduction pathways.

TABLE 49-1 Parts of the Conduction System	
Part	Function
Sinoatrial (SA) node (pacemaker)	Electrical impulses occur at a rate of 60 to 100 beats per minute, initiating the heartbeat with an electrical impulse that causes depolarization
Atrioventricular (AV) node	Delays the electrical impulse to allow for the atria to complete their contraction and ventricles to fill before the next contraction; also serves as a secondary pacemaker if the SA node fails
Bundle of His (AV bundle)	Conducts electrical impulses from the atria to the ventricles
Bundle branches	Conduct impulses down both sides of the interventricular septum
Purkinje fibers (network)	Distribute the electrical impulses throughout the right and left ventricles

The Basic Pattern of the Electrocardiogram

The waves of electrical impulses responsible for the cardiac cycle produce a series of waves and lines on an **electrocardiogram** (abbreviated **ECG** or **EKG**), which is the tracing made by an **electrocardiograph**, an instrument that measures and displays these impulses (Figure 49-2). These peaks and valleys, called waves or **deflections**, are labeled with the letters P, Q, R, S, T, and U. Each letter represents a specific part of the pattern, as explained in Table 49-2. The recognition of abnormalities in the size of the waves or the various time intervals can aid in the diagnosis of certain types of heart problems.

FIGURE 49-2 This ECG tracing shows the pattern of one cardiac cycle in a normal heart. These specific electrical impulses (top) represent the cycle of cardiac contraction and relaxation. The waves and lines (bottom) represent specific parts of the pattern.

TABLE 49-2 ECG Components

Component	Appearance	Heart Activity
P wave	Upward, small curve	Atrial depolarization with resulting atrial contraction
QRS complex	Q, R, and S waves	Ventricular depolarization and resulting ventricular contraction (larger than the P wave); atrial repolarization occurs (not seen)
T wave	Small, upward-sloping curve	Ventricular repolarization
U wave	Small, upward curve	Repolarization of the bundle of His and Purkinje fibers (not always seen); may be seen in instances of electrolyte imbalance
PR interval	P wave and baseline prior to QRS complex	Beginning of atrial depolarization to the beginning of ventricular depolarization
QT interval	QRS complex, ST segment, and T wave	Period of time from the start of ventricular depolarization to the end of ventricular repolarization
ST segment	End of QRS complex to the beginning of T wave	Time between ventricular depolarization and the beginning of ventricular repolarization

► The Electrocardiograph

LO 49.3

Each type of electrocardiograph works in the same way. The electrical impulses produced by the heart can be detected through the skin; these impulses are measured, amplified, and recorded on the ECG. Detection begins with electrodes that conduct and transmit the electrical impulses to the electrocardiograph through insulated wires. An amplifier increases the signal, making the heartbeat visible. The impulses received through various combinations of electrodes constitute different **leads**, or views of the electrical activity of the heart, that are recorded on the ECG. Keep in mind that the term *lead* is used to refer to both the view of the heart on the ECG tracing and the physical location where the electrode is placed on the patient.

Types of Electrocardiographs

Several types of electrocardiographs are in use today. The typical ECG machine sits on a small cart that can be pushed to the person requiring the ECG. The most common machine is a 12-lead electrocardiograph, which records the electrical activity of the heart simultaneously from 12 different views. See Figure 49-3. A single-channel electrocardiograph records the electrical activity of one lead and produces a long, thin strip of ECG paper. This strip, or tracing, is sometimes called

a **rhythm strip**. When ECG tracings are evaluated, discussed later in this chapter, a single lead tracing is either in print or electronic. The multichannel ECG produces a full sheet of paper with all 12 leads. The actual recording time is about 10 seconds. Some models of multichannel ECGs provide a diagnosis or an interpretation of the electrocardiogram. The interpretive option can be turned on or off. Even though the interpretive electrocardiograph can provide a diagnosis, the physician will review the tracing and confirm the diagnosis before treatment is ordered. Larger medical facilities may use an electronic health records (EHR) software program so that electrocardiograms can be inserted into the patient medical record and transmitted to specialists to interpret. Electrocardiograms can be transmitted electronically, by fax or telephone, depending on the software and model of the electrocardiograph (see Figure 49-4).

Electrodes

Disposable electrodes are attached to the patient's skin during electrocardiography (Figure 49-5). Because the skin does not conduct electricity well, an electrolyte (a substance that enhances transmission of electric current) is needed with each electrode. Disposable electrodes come with an electrolyte preparation in place.

When performing routine electrocardiography, you place electrodes on 10 areas of the body: 1 each on the right arm (RA), left arm (LA), right leg (RL), and left leg (LL) and 6 on specific locations on the chest wall. The right leg is designated as the ground. These 10 electrodes are used to evaluate 12 different pathways of the heart's electrical activity (leads). This is why it is called a 12-lead ECG. Evaluating different leads—the electrical activity measured through various combinations of electrodes—enables the physician to pinpoint the origin of certain problems such as dysrhythmias and heart block.

Leads

Each lead provides an image, or view, of the heart's electrical activity from a different angle. Together, the images give the doctor a full picture of electrical activity moving up and down, left and right, and forward and backward through

FIGURE 49-3 A typical ECG machine records three, four, or six leads at a time on a large sheet of graph paper.

© Total Care Programming, Inc

the heart. Monitoring the electrodes on the arms and legs in two different ways produces six leads that record electrical impulses that move up and down and left and right. The electrodes placed on the chest provide six more leads, showing electrical activity moving forward and backward (from the front of the body toward the back and vice versa). Each lead is given a specific designation and code. See Table 49-3.

Limb Leads Of the six leads that directly monitor electrodes on the arms and legs, three are standard and three are augmented. Each of the standard leads monitors two limb electrodes, recording electrical activity between them. These leads are also called *bipolar leads* because they monitor two electrodes. The augmented leads monitor one limb electrode and a point midway between two other limb electrodes, recording electrical activity between the monitored electrode and the midway point. Because they directly monitor only one electrode, augmented leads are also called *unipolar leads*. The electrical activity recorded by these leads is very slight, requiring the machine to augment (amplify) the tracings to produce readable waves and lines on the ECG paper. The standard limb leads appear on the ECG as I, II, and III, and the augmented limb leads appear as aVF (augmented vector-foot), aVR (augmented vector-right), and aVL (augmented vector-left).

Precordial Leads The six precordial, or chest, leads are unipolar leads. The electrodes are placed across the chest in a precise, specific pattern. Each precordial lead monitors one electrode and a point within the heart. The precordial leads are each designated by a letter and a number: V₁ through V₆.

ECG Paper

ECG paper is provided in a long, continuous roll or pad. It is both heat- and pressure-sensitive and is marked with light and dark lines in a standard pattern. Each small square, or square area delineated by dots, measures 1 mm by 1 mm. Each large square measures 5 mm by 5 mm.

TABLE 49-3 ECG Lead Designations

Lead	Electrodes and Points Monitored
Standard limb	
I	RA and LA
II	RA and LL
III	LA and LL
Augmented limb	
aVR	RA and (LA and LL)
aVL	LA and (RA and LL)
aVF	LL and (RA and LA)
Precordial	
V ₁	V ₁ and (LA – RA – LL)*
V ₂	V ₂ and (LA – RA – LL)*
V ₃	V ₃ and (LA – RA – LL)*
V ₄	V ₄ and (LA – RA – LL)*
V ₅	V ₅ and (LA – RA – LL)*
V ₆	V ₆ and (LA – RA – LL)*

*The point within the heart is identified by averaging the readings from the electrodes.

The vertical, or short, axis of the paper records the voltage, or strength of the impulse; the horizontal axis measures time. Normally, the paper moves through the machine at a speed of 25 mm per second. This means the distance across 1 small square represents 0.04 second. The distance across 1 large square represents 0.2 second. The distance across 5 large squares represents 1.0 second. In 1 minute (60 seconds), the paper advances 300 large squares, or 1,500 mm (150 cm).

Each electrocardiograph is standardized before use so that 1 small square represents 0.1 millivolt (mV). One large square represents 0.5 mV, and 2 large squares represent 1.0 mV. See Figure 49-6.

FIGURE 49-6 The ECG paper is standardized and includes heavy lines that allow measurement of both time and voltage. Note that each small box is either 0.1 mV in voltage or 0.04 second in time.

Mundt, Lillian

Electrocardiograph Controls

The location of certain knobs and buttons on an electrocardiograph varies from model to model. However, certain features are common to most machines, including the on/off switch, standardization control, speed selector, sensitivity control, lead selector, centering control, and line control.

On/Off Switch The on/off switch turns the machine on and off. Most machines have an indicator light that signals when the power is on.

Standardization Control Before you obtain an ECG, you must correctly standardize the machine. The standardization control uses a 1-mV impulse to produce a standardization mark on the ECG paper. When you press the standardization control, the stylus should move up 10 small squares, or 10 mm (1 cm) and remain there for 0.08 second (2 small squares, or 2 mm). If it does not, the instrument must be adjusted before you use it. Most newer machines standardize automatically; check the manufacturer's instructions to ensure standardization.

Speed Selector The paper is normally set to run at 25 mm per second for adults. When you run an ECG on infants and children or on adults with a rapid heartbeat, the deflections may appear too close together. In these cases, you may need to adjust the speed to 50 mm per second to separate the peaks and create a tracing that is easier to read. If you must set the speed at 50 mm per second, note it on the strip. Otherwise, a speed of 25 mm per second is assumed. In any case, do not change the speed selection unless the doctor directs you to do so.

Sensitivity Control The sensitivity control—normally set on 1—adjusts the height of the standardization mark and the tracing. When an ECG tracing's height is too high to fit completely on the paper, however, adjust this control to $\frac{1}{2}$ to reduce the size of both the standardization mark and the tracing by half. For tracings that have very low peaks, set this

control on 2 to double the standardization mark and the height of the tracing. Note this change on the ECG. Digital machines standardize the wave output height (gain) automatically and a standardization mark may be seen on the tracing.

Lead Selector Most electrocardiographs have a setting that enables a standard 12-lead tracing to run automatically. All machines have a lead selector that allows you to run each lead individually, in case you need to repeat a strip containing **artifacts**, which are erroneous marks or defects on the tracking.

Centering Control The centering control allows you to adjust the position of the stylus, which must be centered on the paper. Centering the stylus simplifies the process of measuring wave heights for the person who interprets the ECG.

Line Control Another control allows you to adjust the temperature of the stylus. A higher temperature results in a heavier line, whereas a lower temperature results in a lighter, thinner line. The line should be clear without being so dark that it bleeds or smears on the ECG paper. Newer ECG machines do not have a temperature control but may have an adjustment to change the line. Check the manufacturer's directions.

▶ Performing an ECG

LO 49.4

You must obtain a good-quality tracing when performing electrocardiography. To do so, you must be able to recognize an artifact or a generally defective ECG tracing when you see one. Proper technique is also essential to help you obtain the best-quality tracing. The following sections guide you through the general process; however, you must be familiar with the equipment you will be using. The steps in obtaining a standard 12-lead ECG are listed in Procedure 49-1 at the end of this chapter.

Preparing the Room and Equipment

Be sure the room and equipment are properly set up before you begin to administer an electrocardiogram. The accuracy of an ECG can sometimes be affected by electrical currents emitted from nearby machines. Although some electrocardiographs have filters to minimize outside electrical interference, it is always a good idea to perform electrocardiography in a room where all other electrical equipment—air conditioners, refrigerators, fans, and laboratory and diagnostic equipment—is turned off.

The room should be in a quiet, private location, protected from interruptions. Because the patient must partially disrobe, adjust the room temperature to a comfortable level.

The examining table should be sturdy and comfortable. Make sure the table paper is fresh and the table is disinfected after each patient's use.

Before using the electrocardiograph, check the date of its last inspection. Each machine should be periodically inspected and certified safe to use for a specific period of time. Using a machine only within this time period helps ensure both your and the patient's safety. It is good practice to check the

ECG paper and ECG electrodes prior to preparing the patient, restocking these supplies if necessary, as this will save time for you and the physician.

Preparing the Patient

Introduce yourself to the patient, explain the procedure, and answer any questions the patient has. Keep in mind, some patients are apprehensive about undergoing electrocardiography. Anxiety often stems from the fear of receiving an electric shock from the machine. See the *Caution: Handle with Care* section for ways to allay a patient's anxiety about having an ECG.

Applying the Electrodes and the Connecting Wires

You must prepare the patient's skin before applying the electrodes. Proper contact between an electrode and the skin allows for proper conduction of the impulses. Depending on your office policy, you may be required to trim chest or leg hair if it is dense to ensure proper contact. This should be done with scissors. Shaving is not allowed because of the risk of infection or bleeding.

Electrodes Apply disposable electrodes by simply removing the adhesive backing and pressing the electrode firmly into place on the skin. You must position electrodes at 10 locations on the body (Figure 49-7). This includes 4 limb electrodes and 6 chest electrodes.

Limb Electrodes Limb electrodes are most commonly placed on the inside of the fleshy part of the calf muscle and on the outside of the upper arm. Sometimes they are placed on the thigh, on the abdomen, and above the wrist. Follow office policy on limb placement, but remember, a consistent technique will ensure that all ECGs will be standardized, even with different equipment models. It is generally better to place arm electrodes on the upper arm because this reduces the amount of artifact caused by arm movement. Attach the electrodes to a smooth and fleshy part of each limb to ensure optimal conduction of impulses. Limb electrodes must always be placed at the same level on both arms and on both legs. If a patient has had a leg amputated, both leg electrodes should be placed on the thighs or abdomen, parallel to each other. If the patient has had an arm amputated, place both electrodes at shoulder level. Note the alternate electrode placement in the patient's chart and the ECG tracing, because differences in placement can cause changes in the ECG tracing.

Precordial Electrodes Unlike the limb electrodes, the precordial electrodes must be placed at precise, specific locations on the chest to obtain accurate readings. These locations specify intercostal spaces—the spaces between the ribs—which are numbered from top to bottom. Refer to Figure 49-8 for the exact description of each location.

Determine the position for the first precordial electrode (V_1) by counting to the fourth intercostal space to the right of the sternum (breastbone). The V_1 electrode should be placed over this space, directly adjacent to the sternum. After you

FIGURE 49-7 There are 10 electrode positions for electrocardiography.

have this electrode in place, use it as a guide to position the other electrodes.

Place the V_2 electrode in the fourth intercostal space to the left of the sternum in the same manner. Note that the V_1 and V_2 positions may not line up exactly; one may be higher than the other. Perfect symmetry is rare in the human body.

Next, place the V_4 electrode in the fifth intercostal space, where it intersects an imaginary line drawn straight down from the middle of the clavicle (midclavicular line). When the V_4 electrode is in place, place the V_3 electrode midway between V_2 and V_4 in the fifth intercostal space.

Place the V_6 electrode in the fifth intercostal space directly below the middle of the armpit (midaxillary line). Place the last electrode (V_5) in the fifth intercostal space midway between V_4 and V_6 .

Attaching the Wires After placing the electrodes, attach the wires that connect the electrodes to the electrocardiograph. Numbers and letters on the wires correspond to numbers and letters for the electrodes. For example, RA stands for right arm, LL stands for left leg, and so on. The precordial

electrode wires are labeled V_1 through V_6 . Connect the limb wires first, then the precordial wires, in the sequence already described. Some wires are also color-coded.

Connect the wires to the electrodes using the clips or snaps on the end of the wires. Wires should follow the patient's body contours and lie flat against the body. Drape the wires over the patient to avoid putting tension on the electrodes, which could cause interference. You also may bundle the wires together to form a single cable.

Operating the Electrocardiograph

Before running the ECG, remind the patient to remain as still as possible and not to talk.

Preparing the Electrocardiograph Enter patient identifying information into the ECG machine's LCD display. If the machine does not allow data entry, write the information on the tracing report once completed.

Standardization may be necessary; however, digital ECG machines standardize the wave output heights automatically. These calibration marks can be seen at the beginning or end

CAUTION: HANDLE WITH CARE

Allaying Patient Anxiety About Having Electrocardiography

The most common reason for a patient's anxiety is not knowing what to expect from electrocardiography. The patient may be fearful of being hooked up to an electrical device and worried about receiving an electric shock.

Calmly and simply explain the procedure in detail, both before you begin and while you prepare the patient for the test. Assure her it is a safe procedure that will last less than 15 minutes. Explain that the machine measures the heart's electrical activity and that no outside electricity will pass through the body. It is also helpful to explain why the doctor has ordered the procedure, without giving any diagnosis or prognosis.

Above all, talk to and listen to the patient. Encourage her to express her concerns and ask questions. Respond to the patient's concerns and questions calmly, fully, and respectfully.

Ensuring Patient Comfort

Ensuring that the patient is comfortable will help her feel more at ease. It also will result in less body movement and a more accurate ECG.

First, make sure the room temperature is right for the patient. If she says the room feels too cool, provide an extra blanket to prevent chills, as this can make a patient shiver and increase her anxiety. Shivering can cause muscle tremor artifacts. Next, ensure that the patient is comfortable on the examining table. Placing a small pillow under the head can help, but make sure it does not touch the shoulders or raise them off the table. For most patients, placing a pillow under the knees helps relax the abdomen and lower extremities and prevents lower back pain. Try this arrangement and let the patient decide if this feels comfortable. If the patient has trouble breathing, shift her into a sitting-up (Fowler's or semi-Fowler's) position. Use the position that is most comfortable for the patient. If the patient chooses a position other than on her back (supine), be sure to note the position in her chart.

- V₁ Fourth intercostal space (between the ribs), to the right of the sternum (breastbone)
- V₂ Fourth intercostal space, to the left of the sternum
- V₄ Fifth intercostal space, on the left midclavicular line
- V₃ Fifth intercostal space, midway between V₂ and V₄
- V₆ Fifth intercostal space, on the left midaxillary line
- V₅ Fifth intercostal space, midway between V₄ and V₆

FIGURE 49-8 Six precordial electrodes are arranged in specific positions on the chest. Notice that electrode V₄ must be positioned before V₃ and V₆ before V₅.

of a 12-lead tracing. See Figure 49-9. For manual standardization, check the manufacturer's instructions.

Running the ECG You can now run the ECG. On most machines, turning the lead selector to the automatic mode

produces a standard 12-lead strip. Because each lead provides a specific view of the heart's electrical activity, each of the 12 leads has a characteristic tracing (Figure 49-9).

Multiple-Channel Electrocardiographs Some electrocardiographs have multiple channels that can record three, four, or six leads simultaneously (Figure 49-10). Electrode placement is the same as for single-channel electrocardiographs.

Checking the ECG Tracing After running the 12 leads and before disconnecting the patient from the machine, check all tracings to make sure they are clear and free of artifacts. If any of the leads do not appear on a tracing, it may mean a wire has come loose. In this case, reconnect the wire and repeat the tracing. Repeat any unclear tracings.

Also, check that all tracings are contained within the paper's boundaries and that no waves peak above its edges. Increase or decrease the sensitivity setting to adjust the size of the peaks.

If the peaks in a tracing are too close together, increase the paper speed to 50 mm per second. Increasing the speed separates the peaks and makes the tracing easier to read.

Make a note on the ECG tracing whenever it is necessary to adjust sensitivity or speed settings. This information is vital to the interpretation of the test.

Troubleshooting: Artifacts and Other Problems

To ensure high-quality tracings, it is essential to recognize artifacts and identify sources of interference. You also must know how to correct them.

FIGURE 49-9 The tracing from each lead will differ. The long tracing of a single lead along the bottom is the rhythm strip.

Artifacts Improper technique, poor conduction, outside interference, and improper handling of a tracing can cause artifacts. If artifacts are present on an ECG tracing, the licensed practitioner may not be able to make an accurate diagnosis of the patient's condition.

There are several types of artifacts. Among the common ones you may see are a wandering baseline or a flat line. Recognizing the presence of an artifact in the baseline during setup allows you to correct the problem before the tracing is recorded. You also may see marks that are not characteristic

FIGURE 49-10 Some electrocardiographs allow you to run six leads at the same time.

of a tracing; large, erratic spikes; or uniform, small spikes. Table 49-4 outlines these artifacts and summarizes possible causes and solutions. Follow these guidelines to correct artifacts when recording an ECG.

Wandering Baseline A wandering baseline, shown in Figure 49-11, is identified by a shift in the baseline from the center position for that lead. Causes include somatic interference (muscle movement) and a variety of mechanical problems. Mechanical problems may include improper application of electrodes (too loose or incorrectly placed), tension on electrodes caused by a dangling wire, inadequate skin preparation, or the presence of creams or lotions on the skin.

Having the patient lie still can reduce somatic interference. Proper skin preparation and electrode placement are also essential. When the electrocardiography appointment is made, instruct the patient to use no creams or lotions, deodorant, perfume, or powder. Be sure to include specific instructions in patient education materials and ask the patient whether any of these substances were used before the procedure. If so, clean each area of electrode placement thoroughly with alcohol to avoid conduction disturbances.

Flat Line A flat line on one of the lead's tracings (Figure 49-12) is typically caused by a loose or disconnected wire. If flat lines occur on more than one lead, two of the wires may have been switched. If flat lines occur on all leads, the patient cable may be loose or disconnected, or there may be a break (short) somewhere in the unit. On the other hand, a flat line on all leads can indicate cardiac arrest. If a flat line occurs on all leads, always check the patient's pulse and respiration first.

Alternating Current (AC) Interference AC interference occurs when the electrocardiograph picks up a small amount of electric current given off by another piece of electrical equipment. The tracing's line will be jagged, consisting of a series of uniform, small spikes (Figure 49-13). Many newer electrocardiographs have filters to reduce or eliminate most of this interference, and it often can be eliminated by turning off or unplugging other appliances in the room. Keeping the examining table away from the wall also can help, as wiring in the wall can contribute to AC interference. If the wires are crossed and the lead wires are not following the patient's body contour, this can cause AC interference. Make

FIGURE 49-11 A wandering baseline may be caused by somatic interference or a mechanical problem.

TABLE 49-4 Correcting ECG Artifacts

Problem	Possible Causes	Solutions
Wandering baseline	Poor skin preparation Loose electrode Improper electrode placement Somatic interference Pickup of breathing movement Tension on electrode	Repeat skin preparation and lead placement. Reapply electrode. Reapply electrode. Help patient relax and be comfortable. Reposition electrode. Drape wires over patient.
Flat line	Detached/loose wire or cable Crossed wires Short circuit in wires Cardiac arrest	Reattach wires or cable. Check/switch wires. Check/replace broken equipment. Check pulse/respiration; begin CPR.
Marks not part of tracing	Careless handling Use of paper clips Wet hands	Handle carefully. Use a rubber band. Ensure that hands are dry.
Uniform, small spikes	AC interference Improper electrode placement Inadequate grounding Dirty electrode	Turn off/unplug other electrical equipment; remove patient's watch. Reapply electrode. Check and apply proper grounding. Clean and reapply electrode.
Large, erratic spikes	Somatic interference Loose/dry electrode	Help patient relax and be comfortable. Reapply electrode.

**FIGURE 49-12** A flat line on one of the leads is caused by a loose or disconnected wire.

FIGURE 49-13 This type of artifact is caused by AC interference.

sure the ECG cable is not underneath the examination table. If these remedies do not work, check to see whether the electrodes are dirty or attached improperly or whether the machine is incorrectly grounded.

Somatic Interference Muscle movement—tensing of voluntary muscles, shifting of body position, tremors, or even talking (which requires muscular contractions that generate electrical impulses)—causes somatic interference. A sensitive electrocardiograph detects these impulses, possibly resulting in large, erratic spikes and a shifting baseline (Figure 49-14).

Eliminate this type of interference by reminding the patient to remain still and to refrain from talking. To reduce the chance of the patient shivering, shifting, and moving, be sure the room temperature is comfortable for the patient.

Placing the limb electrodes closer to the body's trunk—on the upper arms, close to the shoulder, and on the upper thighs—can reduce interference. Reducing patient anxiety by explaining the procedure also can help reduce somatic interference.

Certain nervous system disorders, such as Parkinson's disease, cause patients to experience involuntary movements that

FIGURE 49-14 The somatic interference in this ECG was caused by patient tremors.

can cause interference. So, although placing the limb electrodes closer to the body's trunk is often helpful, it may be necessary to interrupt the tracing until the tremors subside.

Identifying the Source of Interference Frequently, interference is caused by one of the limb electrodes. The source of interference on an ECG can be identified by checking the ECG tracings obtained on leads I, II, and III. If there is a problem with a particular limb electrode, the interference will be prominent in two leads.

Use these guidelines:

- If there is interference in leads I and II on the tracing, check the right arm electrode.
- If there is interference in leads I and III, check the left arm electrode.
- If there is interference in leads II and III, check the left leg electrode.

If the cause of the artifact or the source of interference cannot be determined, stop the machine and notify your supervisor or the physician. Do not disconnect the patient from the electrocardiograph.

Completing the Procedure

When you are sure the quality of all ECG tracings is acceptable, disconnect the patient from the machine. Remove the tracing and label if necessary; then disconnect the wires from the electrodes and remove the electrodes from the patient. Wipe excess electrolyte from the patient's skin with a moist towel if needed. Assist the patient to a sitting position, allowing a moment's rest before assisting the patient from the table. Help the patient dress if necessary, or allow the patient privacy to dress. Remove disposable paper covers from the table and pillows, clean surfaces according to OSHA guidelines, and discard all disposable materials in a biohazardous waste container.

Interpreting the ECG Although you are not responsible for interpreting an ECG as a medical assistant, knowing something about how ECGs are interpreted may allow you to recognize an urgent problem. Some of the features assessed by an ECG include heart rhythm, heart rate, the length and position of intervals and segments, and wave changes. A series of ECGs is often taken before a physician makes a diagnosis. The tracings are compared for changes in a patient's condition, progress, or response to a specific medication.

Heart Rhythm The ECG is the best way to assess heart rhythm—the regularity of the heartbeat. A normal heart rhythm is indicated on the ECG by regularly spaced complexes. In regularly spaced complexes, the distance between one P wave and the next P wave—or one R wave and the next R wave—is consistent. The physician assesses the patient's rhythm by viewing the rhythm strip you obtain from lead II.

Heart Rate The heart rate can easily be determined by counting the number of QRS complexes in a 6-second strip of the tracing (30 large squares at 25 mm per second) and multiplying by 10. Heart rate irregularities may result from conduction abnormalities or reactions to certain drugs.

Intervals and Segments Variations in the length and position of the intervals and segments can indicate many heart conditions, including conduction disturbances and myocardial infarction. For example, following a myocardial infarction, the ST segment will be elevated in the tracing for a period of time. Thus, the ECG can be used to determine not only the occurrence of a myocardial infarction but also whether it occurred recently. Electrolyte disturbances in the blood and drug reactions also can affect intervals and segments.

Wave Changes The direction of certain waves may vary, depending on which lead is being viewed. Normally, each wave should have a similar appearance in each of the leads. Changes in the height, width, or direction of a wave may indicate a problem. During the early stages of a myocardial infarction, for example, the T wave forms a large peak. Not long afterward, the T wave inverts and appears below the baseline.

Cardiac Dysrhythmias Irregularities in heart rhythm are called **dysrhythmias**, also known as *arrhythmias*. Although some dysrhythmias do not cause problems, many of them can be dangerous, so it is important to detect these irregularities with an ECG.

Ventricular Fibrillation (V-fib) Ventricular fibrillation, commonly referred to as *v-fib*, is a life-threatening heart condition in which the ventricles of the heart appear to “quiver” and there is no cardiac output. The patient will quickly lose consciousness, and cardioversion (defibrillation) must be used to stop the dysrhythmia. Ventricular fibrillation is seen in patients experiencing a myocardial infarction. The tracing is often described as a “saw tooth” image (Figure 49-15).

FIGURE 49-15 Ventricular fibrillation resembles and is sometimes referred to as a “saw tooth” pattern.

FIGURE 49-16 This rhythm strip compares a normal deflection to a premature ventricular contraction (PVC).

Premature Ventricular Contractions (PVCs) Premature ventricular contractions (PVCs) are premature heartbeats that originate from the heart's ventricles. A PVC is identified as a beat that occurs early in the cycle, followed by a pause before the next cycle (Figure 49-16). PVCs are premature because they occur before the regular heartbeat. These heartbeats are the result of an irritability of the heart muscle in the ventricles and can be caused by myocardial infarctions, electrolyte imbalances, lack of oxygen, or certain medications. A PVC appears on the ECG as having no P wave, a wide QRS complex, and T waves that deflect in the opposite direction from the R wave.

Atrial Fibrillation Atrial dysrhythmias occur because of electrical disturbances in the atria and/or the AV node, which lead to fast heartbeats (tachycardia). Atrial fibrillation is a common atrial dysrhythmia that causes speedy, multiple electrical signals that fire rapidly from different areas in the atria rather than from the SA node. Causes of atrial fibrillation include myocardial infarction; hypertension; heart failure; mitral valve diseases, such as MVP; overactive thyroid; pulmonary embolisms (blood clots); excessive alcohol consumption; emphysema; and pericarditis. Atrial fibrillation is seen on the ECG as small, irregular, uncoordinated complexes that are difficult to interpret because the P waves cannot be identified (Figure 49-17).

► Exercise Electrocardiography (Stress Testing) and Echocardiography LO 49.5

The resting ECG does not always provide a doctor with enough information to diagnose a problem. A licensed practitioner can use several additional tests for diagnosing heart diseases and disorders. Exercise electrocardiography, more commonly known as a **stress test**, assesses the heart's conduction system during exercise, when the demand for oxygen increases. This test measures a patient's response to a constant or increasing workload. **Echocardiography** uses ultrasound to view the heart in motion. This can be done at rest or after strenuous activity such as riding a bike or walking on a treadmill.

Exercise Electrocardiography

A stress test may be performed on a patient who has had surgery or a myocardial infarction to determine how the heart is functioning. It is sometimes used to screen a patient for heart disease and to determine a patient's ability to undertake an exercise program.

During the procedure, the patient is required to walk on a treadmill, pedal a stationary bicycle, or walk on a stair-stepping ergometer while ECG readings are taken (Figure 49-18). An ergometer measures work performed. You are responsible for preparing the patient for electrocardiography and monitoring blood pressure throughout the procedure. The test continues until the patient reaches a target heart rate, experiences chest pain or fatigue, or develops complications, such as tachycardia or dysrhythmia.

A patient who undergoes stress testing is often suspected of having a heart problem or is recovering from a myocardial

FIGURE 49-17 Atrial fibrillation.

FIGURE 49-18 During a stress test, the patient exercises on special equipment to see how well the heart handles increased physical demands.
© Stockbyte/Getty Images RF

infarction or surgery. Consequently, there may be a risk of cardiac distress, myocardial infarction, or cardiac arrest during testing. Because of the risks, the patient must sign an informed consent form before the procedure and a physician must monitor the patient throughout the test. Emergency medication and equipment, such as a defibrillator, must always be present

in the room. Because of the potential risk, patients may be apprehensive about the test. As a medical assistant, you can be instrumental in helping them feel comfortable about undergoing the procedure and in making the procedure as safe as possible for them. See the *Caution: Handle with Care* section for ways to help a patient safely undergo stress testing.

Echocardiography

The ability to view the moving heart is essential to understanding how the structures within the heart are functioning. An echocardiogram produces a video image of the working heart valves and chambers and shows how well blood moves through these structures. There are several types of echocardiograms:

- **Transthoracic**—the ultrasound transducer is moved around on the chest and or abdomen to produce heart images.
- **Transesophageal**—the transducer is passed into the esophagus, where it produces clearer images of the heart because it is closer to the heart and the sound waves do not have to penetrate the ribs.
- **Doppler**—uses a special type of ultrasound to look at blood flow through the heart. The direction and speed of blood flow through the heart are assessed with this type of test, giving the physician information about coronary artery blockage and heart valve damage.
- **Stress echo**—echocardiography is done before and after exercise or injection of a drug that makes the heart work faster and harder. This is usually done in conjunction with an electrocardiogram to assess how well the heart responds to increased demand.

Pretest Preparation There is usually no special pretest preparation for transthoracic and doppler echocardiography. The patient should not eat a heavy meal prior to a stress

CAUTION: HANDLE WITH CARE

Ensuring Patient Safety During Stress Testing

Although some risk is involved in exercise electrocardiography, the risk of having a myocardial infarction during a stress test is less than 1 in 500. The risk of death is less than 1 in 10,000. Patients are sometimes apprehensive about the procedure, especially patients who have recently had a myocardial infarction. You can help educate patients to reduce their apprehension and prepare them for stress tests. Assist during the procedure using these techniques:

- Ask patients to wear comfortable shoes and clothes so that they will be more comfortable during the exercise portion of the test.
- Inform the patient of the symptoms he can expect during the test—including fatigue, slight breathlessness, an increased heart rate, and increased perspiration—so that the patient will be better able to cope with the test.
- Explain that advance notice of adjustments or changes during the test, such as an increased workload, will be given.
- Assure the patient that there are few risks associated with the test and that the test can be stopped if he experiences chest pain or extreme fatigue.
- Tell the patient that both you and the physician will be monitoring his vital signs during and after the procedure and that all safety precautions will be taken.
- Explain the presence of the safety equipment—for example, the crash cart with medication, equipment, and supplies in the remote chance that an emergency occurs.
- Encourage the patient to report any symptoms during the test. Even symptoms that are not cardiac-related should be reported.
- Observe the patient for signs of distress, and inform the physician immediately if such symptoms appear.

echo. Since patients having transesophageal echocardiography receive a sedative and the transducer is passed into the esophagus, they should not eat for at least 6 hours prior to the test. Make sure you carefully explain all pretest instructions verbally and in writing and give the patient an opportunity to ask any questions. Reassure the patient of the limited risk during the procedure. Finally, have the patient sign a consent form prior to having the echocardiogram.

► Ambulatory Electrocardiography (Holter Monitoring)

LO 49.6

Patients who experience intermittent chest pain or discomfort may have a normal resting ECG and a normal stress test. When this is the case, the electrical activity of the patient's heart can be monitored over a 24-hour period of normal activity to help diagnose the problem. A Holter monitor is used for this purpose.

Function of the Holter Monitor

A **Holter monitor** is an electrocardiography device that includes a microchip or small cassette recorder and is worn around a patient's waist or on a shoulder strap to record the heart's electrical activity. The monitor is connected to electrodes on the patient's chest (Figure 49-19). During the testing period, the patient is asked to perform usual daily activities and to keep a written log of activities undertaken and of stress or symptoms experienced. To aid in the diagnosis, some monitors allow patients to press an event button to mark the area on the recording whenever symptoms appear.

The patient returns to the office at the end of the 24-hour test period to have the monitor and electrodes removed. The recording is analyzed by a computer in the office or at a reference laboratory and a printout of the results is prepared. When the tracing has been evaluated, the doctor can correlate cardiac irregularities, such as dysrhythmias or ST segment changes, with the activities and symptoms listed in the patient's diary.

FIGURE 49-19 The Holter monitor is used to determine electrical activity of a patient's heart over a 24-hour period. This Burdick Vision Holter is one type of monitor.

© Total Care Programming, Inc

In addition to its role as a diagnostic tool, Holter monitoring can be used to evaluate the status of a patient who is recovering from a myocardial infarction. It can indicate progress or the need to change therapy or the rehabilitation plan.

Patient Education

It is an essential that the patient continue normal activities during Holter monitoring. Give the patient the following additional instructions:

- Record all activities, emotional upsets, physical symptoms, and medications taken.
- Wear loose-fitting clothing that opens in the front while wearing the monitor.
- Avoid going near magnets, metal detectors, and high-voltage areas and avoid using electric blankets during the monitoring period. These devices and areas can interfere with the recording.
- Avoid getting the monitor wet. Do not take a bath or shower. A sponge bath is permissible.

Show the patient how to check the monitor to make sure it is working properly. This step is particularly important if any of the electrodes seem loose. Instruct the patient to inform the office if there are any problems.

Connecting the Patient

Holter monitors have either three or five electrodes, depending on the unit. As with a resting ECG, correct placement of the electrodes is necessary for accurate readings. Before connecting the patient to the Holter monitor, make sure he has signed an informed consent form and explain that you need to attach electrodes to the patient's skin.

Because the electrodes must stay in place for 24 hours, you may need to clip the hair in the areas where the electrodes are attached to permit optimum adherence. The wires may be connected to the electrodes before they are attached to minimize patient discomfort.

After the electrodes and wires are attached and the monitor is in place, tape the wires to the patient's chest to eliminate tension on the wires or electrodes. Be sure that the unit has a fresh battery, that a cassette tape or other data storage device has been inserted if necessary, and that the unit is turned on. The steps in performing Holter monitoring are outlined in Procedure 49-2 at the end of this chapter.

► Pulmonary Function Testing

LO 49.7

Pulmonary function tests (PFTs) help the doctor evaluate ventilatory function of the lungs and chest wall. They evaluate lung volume and capacity and are commonly used to evaluate shortness of breath and to help detect and classify pulmonary disorders. They also may be performed as part of a general

examination. PFTs are used to monitor conditions such as asthma, certain allergies, cystic fibrosis, and chronic obstructive pulmonary disease (COPD), a chronic lung disorder. The tests are also used to evaluate the effectiveness of particular treatments on a patient's lung function.

Spirometry

Spirometry is a test used to measure breathing capacity. An instrument called a **spirometer** measures the air taken in by and expelled from the lungs. Several different measurements related to lung volume and capacity can be made with a spirometer. Some of these measurements are made directly by the spirometer; others are calculated. For more information about lung volumes and capacities, see the chapter *The Respiratory System*.

Forced Vital Capacity

Many measurements can be obtained during one particular maneuver—obtaining the **forced vital capacity (FVC)**, the greatest volume of air that can be expelled when a person performs rapid, forced expiration. To obtain the FVC, ask the patient to take as deep a breath as possible and to exhale into the spirometer as quickly and completely as possible. You can determine the lung's ability to function by taking into account the volume of air expelled and the time it takes to perform this maneuver.

Types of Spirometers

Many models of computerized spirometers are used in physicians' offices. Each consists of a mouthpiece or a mouthpiece and a tube to carry air to the machine, a mechanism to measure the volume or flow of air, and a means of calculating and printing the results.

Computerized spirometers measure air volume and airflow, perform various calculations, and print a graphic representation of the information. Figure 49-20 shows a computerized spirometer.

Performing Spirometry

The technique for performing pulmonary function testing is similar for all types of spirometers. Successful spirometry depends on proper patient preparation and consistent

technique in performing the procedure and analyzing the results. The steps involved in measuring forced vital capacity using a spirometer are described in detail here and outlined in Procedure 49-3 at the end of this chapter.

Patient Preparation Certain conditions and activities affect the accuracy of pulmonary function tests. Patients should be made aware of these conditions prior to scheduling to ensure accuracy:

- Viral infection or acute illness within the previous 2 to 3 weeks
- Serious medical condition, such as a recent myocardial infarction
- Recent use of a prescribed medication if the test order calls for spirometry before and after prescribed medication
- Use of a sedative or opioid substance before the test
- Smoking or eating a heavy meal within 1 hour of taking the test

Review the conditions and activities with patients again on the day of the test to ensure that none apply. If there are no contraindications, weigh and measure patients. Use simple terms to explain the procedure and its purpose. Have them loosen tight clothing so that they will be comfortable and their breathing will not be restricted in any way. The procedure is performed with patients sitting down. Make sure their legs are not crossed and that both feet are flat on the floor.

Explain that they need to wear a nose clip or hold the nose tightly closed to be sure they will inhale and exhale through the mouth. The mouthpiece of the unit may be a disposable cardboard tube or a reusable rubber one that can be disinfected after use. If disposable mouthpieces are used, instruct patients to avoid biting down on them, as that will obstruct airflow. Be sure patients form a tight seal around the mouthpiece with their lips. Dentures normally help maintain a tight seal; however, they should be removed if they hinder the process.

Proper Positioning Instruct patients to keep their chin and neck in the correct position during the procedure. The chin should be slightly elevated and the neck slightly extended. Bending the chin to the chest tends to restrict airflow and should be avoided (Figure 49-21). Some bending at the waist is acceptable.

Explaining and Demonstrating the Procedure Tell patients to take the deepest breath possible, insert the mouthpiece into the mouth, form a tight seal, and then blow into the mouthpiece as hard and as fast as possible to completely exhale. Tell them to exhale as long as they can to force air from the lungs. Remind them that the initial force of their exhalation must be strong to get a valid reading. Demonstrate the procedure to show how to do the test correctly.

Performing the Maneuver You can improve patients' performance during the maneuver by actively and forcefully coaching them. Urge patients to blow hard and to continue blowing. After a maneuver, give them feedback on their performance and indicate corrective actions they can take to improve the next maneuver.

FIGURE 49-20 This computerized spirometer measures air volume and airflow.

(b) Incorrect position

FIGURE 49-21 During a pulmonary function test, the patient must maintain the proper position. (a) The chin should be slightly elevated and the neck slightly extended. (b) The chin should not approach the chest.

© McGraw-Hill Education. David Moyer, photographer

Some spirometers indicate whether a particular maneuver was of adequate force and duration to be measured. However, adequate force does not indicate that the maneuver was acceptable. An acceptable maneuver must have the following five features:

1. No coughing, particularly during the first second
2. A quick and forceful start
3. An adequate length of time (a minimum of 6 seconds)
4. A consistent and fast flow with no variability
5. Consistency with other maneuvers

Spirometry tracings plot volume and time. You will need to obtain three acceptable maneuvers, which may require more than three attempts. Observe the patient for signs of breathing difficulty, dizziness, light-headedness, or changes in pulse and blood pressure. If necessary, allow the patient to rest briefly before continuing. Notify the physician immediately if symptoms are severe.

Determining the Effectiveness of Medication Spirometry is often used to determine the effectiveness of certain medications a patient is taking. You will perform two sets of maneuvers if this determination is required. Instruct the patient to refrain from taking the prescribed medication on the day of the test. Before performing the test, confirm that the patient has followed this instruction. Conduct the first set of maneuvers, ensuring that they are acceptable. After obtaining the results, instruct the patient to take the prescribed medication. Allow the medication to take effect, and then perform a second set of maneuvers. Comparing the two sets of readings shows whether the medication has effectively improved the patient's lung function. Some computerized spirometers can graph both sets of readings together to simplify the comparison (Figure 49-22).

Special Considerations On occasion, you may have to deal with an uncooperative patient, one who cannot understand or follow directions, or one who cannot perform the procedure. In these situations, patience and skill are essential for obtaining an acceptable spirometry tracing.

The doctor may be able to convince an uncooperative patient to perform the maneuver. You can help by taking a non-nonsense approach, perhaps stating that the doctor needs these test results to help the patient. Patients who cannot understand or follow directions—the very young, the very old, those who have limited proficiency in English, or those with a hearing impairment—may need extra attention and patience to obtain acceptable results. Explain the procedure in simple terms and repeat instructions as necessary. If, after eight attempts, the

FIGURE 49-22 These spirometry tracings show air volume per second before and after use of a medication.

patient is unable to perform the procedure, stop and report the situation to the doctor.

The Importance of Calibration Spirometers should be calibrated each day they are used to ensure accurate readings. You may be responsible for this procedure, which requires the use of a standardized measuring instrument called a **calibration syringe** (Figure 49-23). When the plunger is pulled back, this syringe contains a fixed volume of air. Connect the syringe to the patient tubing (this tubing runs from the mouthpiece to the machine) and depress the plunger to inject the entire volume of air. The spirometer reading should be within 3% of the stated volume. Keep a calibration logbook for each spirometer.

While calibrating the spirometer, you can detect leaks by checking the volume/time graph. The volume should remain at a steady reading; if it declines with time, a leak exists in the system.

Infection Control After a patient completes the pulmonary function test, you must clean the spirometer and other pulmonary function devices thoroughly to prevent transmission of microorganisms. If disposable mouthpieces, nose clips, and patient tubing are used, discard them in a biohazardous waste container. If reusable mouthpieces, nose clips, and tubing are used, clean and disinfect them between patients. Most important, wash your hands thoroughly before and after performing a pulmonary function test.

Peak Expiratory Flow Rate (PEFR)

A **peak expiratory flow rate (PEFR)** is a measurement taken to determine the amount of air that can be quickly forced from the lungs. A peak flow meter—a small, handheld device that can be used in the medical office or the patient's home (Figure 49-24)—is often used to obtain a PEFR. Patients who suffer from asthma are commonly asked to monitor their asthma by using a peak flow meter and recording their results. During an asthma flare-up, the large airways of the

FIGURE 49-23 A calibration syringe delivers a fixed volume of air.

© Cliff Moore

lungs begin to narrow, which slows the speed of air leaving the lungs. A peak flow meter, when used properly, can reveal narrowing of the airways in advance of an asthma attack. Peak flow meters can help determine

- When to seek emergency medical care.
- The effectiveness of an asthma management treatment plan.
- When to stop or add medication as directed by a physician.
- Asthma triggers, such as stress or exercise.

Procedure 49-4, at the end of this chapter, explains the procedure for obtaining a peak expiratory rate using a peak flow meter.

Peak Flow Zones After obtaining a peak expiratory flow rate, the type of patient care given will be determined based on the individual's results. The physician will instruct the patient about the peak flow zones and how to respond to each zone. Peak flow zones are different for each patient and will be determined by the physician. The three peak flow zones are green, yellow, and red. These three color zones can be seen in Figure 49-24.

Green Zone The green zone indicates good control of asthma, with peak flow rates of 80% to 100% of the highest peak flow rate. Measurements in this zone indicate that air moves well through the large airways and the patient's usual activities can be continued.

FIGURE 49-24 Peak expiratory flow meter markings will determine the patient's treatment based on accurate readings.

© andres balcazar/Getty Images RF

Yellow Zone Peak flow rates in the yellow zone range from 50% to 80% of the highest peak flow rate. Measurements in this zone indicate that the large airways are beginning to narrow and medication is needed. Patient symptoms include tiredness and tightening of the chest.

Red Zone Peak flow rates in the red zone are less than 50% of the highest or best personal reading recorded. Narrowing of the largest airways has occurred and is considered a medical emergency. Medical treatment should be sought immediately. Patients are usually directed to take a bronchodilator or other medication that will open the airway and call their physician. Symptoms include wheezing, shortness of breath, and trouble walking and talking.

Pulse Oximetry

LO 49.8

Pulse oximetry is a noninvasive test that measures the saturation of oxygen in a patient's arterial blood. The pulse oximeter includes a sensor and a monitoring device. The sensor is placed on a patient's finger, earlobe, toe, or bridge of the nose (Figure 49-25). In order for the sensor to detect the oxygen level, there must be a good blood supply at the site where the sensor is placed. For the fingers or toes, you will need to check the capillary refill to determine if the blood supply is adequate. A red infrared light is shone through one side of the appendage to the other. The amount of light absorbed by the hemoglobin

FIGURE 49-25 A pulse oximeter is a portable, handheld device used by many medical facilities.

© McGraw-Hill Education

in the blood is detected by the pulse oximeter. Any reading less than 95% indicates **hypoxemia** (low blood oxygen). Pulse oximetry is performed on patients with pulmonary or cardiac conditions and during postoperative patient observation. It is also used to help diagnose **sleep apnea**, a condition characterized by pauses in breathing during sleep. The pauses are often long enough to cause a drop in blood oxygen levels. Some medications after surgery can slow breathing rates and it is important that patient blood oxygen levels be carefully monitored. Procedure 49-5, at the end of this chapter, explains the process of obtaining a pulse oximetry reading.

PROCEDURE 49-1 Obtaining an ECG

WORK // DOC

Procedure Goal: To obtain a graphic representation of the electrical activity of a patient's heart

OSHA Guidelines:

Materials:

Patient chart/progress note, electrocardiograph, ECG paper, electrodes, electrolyte preparation, wires, patient gown, drape, blanket, pillows, gauze pads, alcohol, moist towel, and scissors for trimming hair (if needed)

Method:

1. Turn on the electrocardiograph. Ensure that there is an adequate paper supply and that the machine inspection is up to date.
2. Identify the patient, introduce yourself, and explain the procedure.

3. Wash your hands.
4. Ask the patient to disrobe from the waist up and remove jewelry, socks or stockings, bra, and shoes. If the electrodes will be placed on the patient's legs, have the patient roll up his or her pant legs. Sometimes the electrodes are placed on the sides of the lower abdomen—check the manufacturer's instructions. Provide a gown if the patient is female and instruct her to wear the gown with the opening in front.
RATIONALE: *Making sure the patient knows exactly what clothing to remove and the correct way to put on the gown will make the process more efficient.*
5. Assist the patient onto the table and into a supine position. Cover the patient with a drape (and a blanket if the room is cool). If the patient experiences difficulty breathing or cannot tolerate lying flat, use a Fowler's or semi-Fowler's position, adjusting with pillows under the head and knees for comfort if needed.
6. Tell the patient to rest quietly and breathe normally. Explain the importance of lying still to prevent false readings.

7. Wash the patient's skin, using gauze pads moistened with alcohol. If needed, rub it vigorously with dry gauze pads to promote better contact of the electrodes.

RATIONALE: *If a patient has applied lotion in the areas where electrodes are placed, it may cause conduction problems.*

8. If the patient's leg or chest hair is dense, use a small pair of scissors to closely trim the hair where you will attach the electrode. (Shaving is not allowed because of the risk of bleeding and infection.)
9. Apply electrodes to fleshy portions of the limbs, making sure the electrodes on one arm and leg are placed similarly to those on the other arm and leg. Attach electrodes to areas that are not bony or muscular. The arm lead tabs on the electrode point downward and the electrode tabs for the leg leads point upward. Peel off the backings of the disposable electrodes and press them into place.

RATIONALE: *Using the correct tab position will reduce tension on the limb wires. Artifacts can occur when electrodes are placed on bones and muscles.*

FIGURE Procedure 49-1 Step 9 Place electrodes at the specified locations on the chest, arms, and legs.

© McGraw-Hill Education

10. Apply the precordial electrodes at specified locations on the chest. If you are unsure of the placement, check a reliable reference. Precordial electrode tabs point downward.
11. Attach wires and cables, making sure all wire tips follow the patient's body contours.
12. Check all electrodes and wires for proper placement and connection; drape wires over the patient to avoid creating tension on the electrodes, which could result in artifacts.

FIGURE Procedure 49-1 Step 12 Attach wires and cables, draping wires over the patient to avoid tension, which can result in artifacts.

© McGraw-Hill Education

13. Enter the patient data into the electrocardiograph. Press the on, run, or record button. If standardization is needed, check the manufacturer's instructions.
 14. Remind the patient to lie quietly, and run the ECG.
 15. Check tracings for artifacts.
 16. Correct problems and repeat any tracings that are not clear.
 17. Disconnect the patient from the machine.
 18. Remove the tracing from the machine and label it with the patient's name, the date, and your initials if these do not print out with the tracing.
 19. Disconnect the wires from the electrodes and remove the electrodes from the patient.
 20. Clean the patient's skin with a moist towel.
 21. Assist the patient into a sitting position.
 22. Allow a moment for rest and then assist the patient from the table.
- RATIONALE:** *Some patients may experience postural hypotension after lying and may feel dizzy.*
23. Assist the patient in dressing if necessary, or allow the patient privacy to dress.
 24. Wash your hands.
 25. Record the procedure in the patient's chart/progress note.
 26. Properly dispose of used materials and disposable electrodes.
 27. Clean and disinfect the equipment and the room according to OSHA guidelines.

PROCEDURE 49-2 Holter Monitoring

WORK // DOC

Procedure Goal: To monitor the electrical activity of a patient's heart over a 24-hour period to detect cardiac abnormalities that may go undetected during routine electrocardiography or stress testing

OSHA Guidelines:

Materials: Patient chart/progress note, Holter monitor, battery, microchip or small cassette, patient diary or log, alcohol, gauze pads, scissors, disposable electrodes, hypoallergenic tape, drape, and electrocardiograph

Method:

1. Identify the patient, introduce yourself, and explain the procedure.
2. Ask the patient to remove clothing from the waist up; provide a drape if necessary.

3. Wash your hands and assemble the equipment.
4. Assist the patient into a comfortable position (sitting or supine).
5. If the patient's body hair is particularly dense, don examination gloves and trim the areas where the electrodes will be attached.
RATIONALE: *Trimming the area will ensure that the electrodes will stay secure during the 24-hour period.*
6. Clean the electrode sites with alcohol and gauze.
7. Rub each electrode site vigorously with a dry gauze square.
RATIONALE: *To help electrodes adhere to the skin.*

8. Attach wires to the electrodes and peel off the paper backing on the electrodes. Apply electrodes at locations as indicated by the manufacturer's instructions. Press firmly to ensure that each electrode is making good contact with the skin.
RATIONALE: *Good skin contact is essential to obtain an accurate reading.*

FIGURE Procedure 49-2 Step 7 Rub each electrode site vigorously to ensure that the electrodes adhere and stay in place during the monitoring.
 © McGraw-Hill Education

FIGURE Procedure 49-2 Step 8 Correctly connecting the patient to the Holter monitor is essential. Check the manufacturer's instructions for the monitor you are using.
 © David Kelly Crow

9. Attach the patient cable.
10. Insert a fresh battery, and position the unit.

FIGURE Procedure 49-2 Step 10 Make sure that the monitor has a microchip or other type of data storage and a fresh battery.
 © 2014 SCHILLER AG

11. Tape wires, cable, and electrodes as necessary to avoid tension on the wires as the patient moves.
12. Insert the microchip or cassette, and turn on the unit.
13. Ensure that the unit is on and indicate the start time in the patient's chart.
RATIONALE: *If the unit is not running, results will not be recorded and the test will have to be repeated.*
14. Instruct the patient on proper use of the monitor and how to enter information in the diary. Caution the patient not to alter any diary entries; it is crucial to know what the patient is doing at all times.
15. Schedule the patient's return visit for the same time on the following day.
16. On the following day, remove the electrodes, discard them, and clean the electrode sites.
17. Wash your hands.
18. Transfer the data from the monitor to the patient's chart according to office procedure and the manufacturer's directions.
19. Document the procedure (refer to Progress Note).

BWW PROGRESS NOTE
⏏

Patient Name:

Holter monitoring placed at 0900. Patient instructed how to maintain diary during monitoring period and to return to clinic on 10/28/XX. Patient stated he understood and had no questions.

PROCEDURE 49-3 Measuring Forced Vital Capacity Using Spirometry

WORK // DOC

Procedure Goal: To determine a patient's forced vital capacity using a volume-displacing spirometer

OSHA Guidelines:

Materials: Patient chart/progress note, adult scale with height bar, spirometer, patient tubing (tubing that runs from the mouth-piece to the machine), mouthpiece, nose clip, and disinfectant

Method:

1. Prepare the equipment. Ensure that the paper supply in the machine is adequate.
2. Calibrate the machine as necessary.
3. Identify the patient and introduce yourself.
4. Check the patient's chart to see whether there are special instructions to follow.
5. Ask whether the patient has followed instructions.
6. Wash your hands and don examination gloves.
7. Measure and record the patient's height and weight.
8. Explain the proper positioning.
9. Explain the procedure.

10. Demonstrate the procedure.

RATIONALE: *Explanations and demonstrations are effective patient teaching methods.*

11. Turn on the spirometer and enter applicable patient data and the number of tests to be performed.
12. Ensure that the patient has loosened any tight clothing, is comfortable, and is in the proper position. Apply the nose clip.

FIGURE Procedure 49-3 Step 12 The nose clip is applied over the fleshy part of the nose.

© McGraw-Hill Education

13. Have the patient perform the first maneuver, coaching when necessary.

FIGURE Procedure 49-3 Step 13 You may need to coach the patient while performing the maneuver.

© McGraw-Hill Education

14. Determine whether the maneuver is acceptable.
15. Offer feedback to the patient and recommendations for improvement if necessary.

16. Have the patient perform additional maneuvers until three acceptable maneuvers are obtained.
17. Record the procedure in the patient's chart and place the chart and the test results on the physician's desk for interpretation.
18. Ask the patient to remain until the physician reviews the results.
RATIONALE: *The physician may want to speak with the patient regarding results or may want to order additional testing.*
19. Properly dispose of used materials and disposable instruments.
20. Sanitize and disinfect patient tubing, reusable mouthpiece, and nose clip.
21. Clean and disinfect the equipment and room according to OSHA guidelines.

PROCEDURE 49-4 Obtaining a Peak Expiratory Flow Rate

WORK // DOC

Procedure Goal: To determine a patient's peak expiratory flow rate

OSHA Guidelines:

Materials: Patient chart/progress note, peak flow meter, and a disposable mouthpiece

Method:

1. Assemble all necessary equipment and supplies for the test.
2. Wash your hands and identify the patient.
3. Explain and demonstrate the procedure to the patient.
RATIONALE: *Patient education and understanding are crucial for getting accurate test results.*
4. Position the patient in a sitting or standing position with good posture. Make sure any chewing gum or food is removed from the patient's mouth.
5. Set the indicator to zero.
RATIONALE: *Helps to ensure accurate results*
6. Ensure that the disposable mouthpiece is securely placed onto the peak flow meter.
7. Hold the peak flow meter with the gauge uppermost and ensure that your fingers are away from the gauge.
8. Instruct the patient to take as deep a breath as possible.
9. Instruct the patient to place the mouthpiece into his mouth and close his lips tightly around the mouthpiece, sealing his lips around it.

FIGURE Procedure 49-4 Step 6 A disposable mouthpiece is securely fastened to the peak flow meter.

© McGraw-Hill Education

FIGURE Procedure 49-4 Step 9 Have the patient close his lips tightly around the mouthpiece so that no air escapes.

© McGraw-Hill Education

10. Instruct the patient to blow out as fast and as hard as possible.
RATIONALE: *A fast blast is better than a slow blow.*

11. Observe the reading where the arrowhead is on the indicator.
12. Reset the indicator to zero and repeat the procedure two times, for a total of three readings. You will know the technique is correct if the reading results are close. If coughing occurs during the procedure, repeat the step.
13. Document the readings in the patient's chart. The highest reading will be the peak flow rate.

RATIONALE: *The highest reading represents the personal best reading for the patient, and future measurements are based on this result. Do not average the results.*

14. Dispose of the mouthpiece in a biohazardous waste container.
15. Disinfect or dispose of the peak flow meter per office policy.
16. Wash your hands.

PROCEDURE 49-5 Obtaining a Pulse Oximetry Reading WORK // DOC

Procedure Goal: To obtain a pulse oximetry reading

OSHA Guidelines:

Materials: Pulse oximeter, patient chart/progress note

Method:

1. Assemble all the necessary equipment and supplies.
2. Wash your hands and correctly identify the patient.
3. Select the appropriate site to apply the sensor by assessing the capillary refill in the patient's toe or finger. This is done by applying pressure to the nail bed until it turns white, then releasing the pressure and watching for the return of blood flow. The pink color should return in less than 2 seconds.

RATIONALE: *If the patient has poor circulation in his fingers or toes, use the bridge of his nose or an earlobe.*

4. Prepare the selected site, removing nail polish or earrings if necessary. Wipe the selected site with alcohol and allow it to air-dry.

RATIONALE: *Nail polish can alter the test results.*

5. Attach the sensor to the site (if a finger is used, place the finger in the clip).
6. Instruct the patient to breathe normally.
7. Attach the sensor cable to the oximeter. Turn on the oximeter and listen to the tone.
8. Set the alarm limits for high and low oxygen saturations and high and low pulse rates, as directed by the physician's order, and turn on the oximeter.
9. Read the saturation level and document it in the patient's chart. Report to the physician readings that are less than 95%. Manually check the patient's pulse and compare it to the pulse oximeter. Document all the readings and the application site in the patient's chart/progress note.
10. Wash your hands.
11. Rotate the patient's finger sites every 4 hours if using a pulse oximeter long-term.

FIGURE Procedure 49-5 Step 3 The earlobe and bridge of the nose are alternative sites for placement of the sensor during pulse oximetry.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
49.1 Discuss the medical assistant's role in electrocardiography and pulmonary function testing.	As a medical assistant, you will be responsible for preparing the patient for ECG and pulmonary function tests, maintaining the equipment used for these tests, and performing them.
49.2 Explain the basic principles of electrocardiography and how it relates to the conduction system of the heart.	The heart's conduction system is responsible for the electrical pathway that occurs during a heartbeat. The pathway begins with the SA node, travels through the AV node, the bundle of His, the right and left bundle branches, and ends with the Purkinje fibers. This electrical energy pathway is measured with an electrocardiograph and a tracing of the impulses is produced. The electrical impulses are represented in wave forms or deflections. Each deflection is labeled by letters PQRSTU and represents a part of the pattern.
49.3 Identify the components of an electrocardiograph and what each does.	The electrocardiograph consists of the following components: electrodes, which detect and conduct electrical impulses to the electrocardiograph; amplifier, which increases the signal, making the heartbeat visible; leads, combinations of electrodes with each providing different views of the electrical activity of the heart; LCD display and/or ECG paper, where the tracing of the electrical activity is viewed and recorded; and various controls that allow you to input the patient information and change such things as the speed of the tracing.
49.4 Carry out the steps necessary to obtain an ECG.	The steps in obtaining an accurate ECG include preparing the room and equipment, identifying the patient, properly placing the limb and chest electrodes, attaching the lead wires, entering the patient data into the ECG machine, running the tracing, checking the tracing for artifacts, disconnecting the patient from the lead wires and removing the electrodes, and assisting the patient as required.
49.5 Summarize exercise electrocardiography and echocardiography.	Exercise electrocardiography is referred to as <i>stress testing</i> . This measures the efficiency of the heart during constant or increasing workload. Echocardiography uses ultrasound to create a picture of the moving heart. This can be done while the patient is resting or after exercise.
49.6 Explain the procedure of Holter monitoring.	A Holter monitor is used to measure the heart's activity over an extended period, usually 24 hours. This is used when the patient has intermittent chest pain or discomfort and a normal ECG and stress test do not identify the cause.
49.7 Carry out the various types of pulmonary function tests.	Forced vital capacity is the measurement of the greatest volume of air expelled when a patient performs a rapid, forced expiration. The lung's ability to function is measured by the volume of air expelled and the time taken to perform the maneuver. Accurate spirometry testing includes positioning the patient properly, coaching the patient during the procedure, obtaining three acceptable maneuvers, and recording the results in the patient's chart. A peak expiratory flow rate is obtained by having the patient sit or stand using good posture, take in as deep a breath as possible, and blow out through the peak flow meter as fast and as hard as possible three times. The highest reading of the three is the peak flow rate and should be recorded in the patient's chart.

LEARNING OUTCOMES**49.8 Describe the procedure for performing pulse oximetry testing.****KEY POINTS**

Pulse oximetry testing is performed by applying the pulse oximeter to the patient's finger or toe, attaching the sensor cable to the oximeter, turning the oximeter on, setting the alarm limits for high and low oxygen saturations, and reading the patient's oxygen saturation levels. The oxygen saturation levels should be recorded in the patient's chart.

C A S E S T U D Y C R I T I C A L T H I N K I N G

© McGraw-Hill Education

Recall John Miller from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. Explain to John the difference between an ECG and an echocardiogram.

2. John expresses concern about having a heart attack during the procedure. How can you alleviate his fear?
3. You must perform an ECG on this patient. Describe the steps in the procedure.

E X A M P R E P A R A T I O N Q U E S T I O N S

1. (LO 49.2) Which of the following initiates the heartbeat?
 - a. AV node
 - b. SA node
 - c. Bundle of His
 - d. Purkinje fibers
 - e. Bundle branch
2. (LO 49.4) The ECG tracing is showing somatic interference. What can be done?
 - a. Turn off or unplug appliances in the room
 - b. Remove oil from the patient's skin
 - c. Connect a loose wire
 - d. Remind the patient to remain still
 - e. Reschedule the test
3. (LO 49.8) What does a pulse oximeter measure?
 - a. Oxygen saturation of the blood
 - b. Oxygen saturation of the skin
 - c. Electrical activity of the heart
 - d. Forced vital capacity
 - e. Lung capacity
4. (LO 49.7) When obtaining a peak flow rate, you should _____ the _____ readings.
 - a. Average, two
 - b. Average, three
 - c. Add, two
 - d. Document, three
 - e. Document, two
5. (LO 49.4) Which of the following irregularities on an ECG would be considered the *most* severe?
 - a. PVC
 - b. V-fib
 - c. A-fib
 - d. AC interference
 - e. Tachycardia
6. (LO 49.3) The precordial ECG leads are also called
 - a. AVR leads
 - b. Ground leads
 - c. Chest leads
 - d. Augmented leads
 - e. Limb leads
7. (LO 49.6) Which of the following should a patient do when wearing a Holter monitor?
 - a. Avoid normal daily activities and focus on relaxing during the monitoring
 - b. Bathe and/or shower as usual because the monitor will not be affected
 - c. Wear a tight-fitting shirt to hold the electrodes and monitor in place
 - d. Return the Holter monitor through the mail to avoid a return visit
 - e. Inform the office if the monitor is not working properly

8. (LO 49.4) Turning off unnecessary electrical equipment in the room when performing an ECG is helpful in reducing which type of artifact?
- Extraneous marks
 - Flat line
 - Somatic interference
 - AC interference
 - Wandering baseline
9. (LO 49.8) Low blood oxygen is known as
- Hypoxemia
 - Sleep apnea
 - Hyperpnea
 - Oximetry
 - COPD
10. (LO 49.7) The greatest volume of air that can be expelled when a person performs rapid, forced expiration is
- Peak expiratory flow
 - Total lung capacity
 - Maximum voluntary ventilation
 - Forced vital capacity
 - Tidal volume

SOFT SKILLS SUCCESS

- Andrea Hochradel arrives to have her Holter monitor removed. She sits down in the exam room, takes the monitor and all the electrodes and wires out of her purse, and plops them on the table. What should you do?
- John Miller arrives for a pulmonary function test and he has just finished a cigarette. How should you handle this situation?

ductal carcinoma (IDC). Dr. Williams refers Raja to a radiation oncologist for treatment. She will most likely be treated with brachytherapy.

Keep Raja in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 50, you will be able to:

- 50.1** Explain what X-rays are and how they are used for diagnostic and therapeutic purposes.
- 50.2** Compare invasive and noninvasive diagnostic procedures.
- 50.3** Carry out the medical assistant's role in X-ray and diagnostic radiology testing.
- 50.4** Discuss common diagnostic imaging procedures.
- 50.5** Describe different types of radiation therapy and how they are used.
- 50.6** Explain the risks and safety precautions associated with radiology work.
- 50.7** Relate the advances in medical imaging to EHR.

KEY TERMS

- | | |

| brachytherapy | myelography |
| cholangiography | noninvasive |
| contrast medium | nuclear medicine |
| diagnostic radiology | PET |
| dual-energy X-ray absorptiometry (DXA) | radiation therapy |
| intravenous pyelography (IVP) | retrograde pyelography |
| invasive | SPECT |
| | teletherapy |

- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- V.A.4** Explain to a patient the rationale for performance of a procedure

- 2. Anatomy and Physiology**
 - c. Identify diagnostic and treatment modalities as they relate to each body system
- 8. Administrative Procedures**
 - e. Maintain inventory of equipment and supplies
 - (1) Perform routine maintenance of administrative equipment
- 9. Clinical Procedures**
 - a. Practice standard precautions and perform disinfection/sterilization techniques

► Introduction

Diagnostic radiology has evolved immensely since the discovery of the simple X-ray beam, which has become a valuable screening and clinical diagnostic tool for physicians. In this chapter, you will learn the basics of noninvasive and invasive radiology along with your role as a medical assistant in this testing. Safety issues for the administration of radiologic testing are discussed, as are the proper handling and storage of the films. In addition, you will learn about preparing and instructing patients for the more common radiology procedures.

► Brief History of the X-ray LO 50.1

In 1895, Wilhelm Konrad Roentgen (1845–1923) discovered the X-ray, or roentgen ray, a type of electromagnetic wave. It has a high energy level, traveling at the speed of light (186,000 miles per second), and an extremely short wavelength (one-billionth of an inch) that can penetrate solid objects. X-rays react with photographic film to produce a permanent record (X-ray, or radiograph). The X-ray image is lightest where the film is struck by the least X-ray energy. Differences in tissue densities produce the X-ray image, with the most dense—such as bone—being lightest and the least dense—such as air in the lungs—being darkest on the film.

Today, X-rays and radioactive substances have both diagnostic—such as a wrist X-ray to diagnose a fracture—and therapeutic—such as radiation treatment for cancerous tumors—uses. Radiologic technologists are trained medical personnel, certified to perform certain radiologic procedures upon completion of a 2- to 4-year radiology curriculum. Some radiologic technologists receive further training in radiology subspecialties, such as ultrasound, mammography, magnetic resonance imaging, and nuclear medicine. Radiographers, sonographers, radiation therapists, and nuclear medicine technologists are all radiologic technologists. Invasive radiologic procedures and procedures requiring a high degree of expertise are nearly always performed by a radiologist—a physician who specializes in radiology. A radiologist is also the physician who interprets the films for other physicians. Other

specialists who perform radiologic procedures, either alone or with a radiologist's assistance, include cardiologists, orthopedists, obstetricians, and oncologists.

► Diagnostic Radiology LO 50.2

Diagnostic radiology is the use of X-ray technology for diagnostic purposes. Radiologic tests sometimes use contrast media as well as special techniques or instruments for viewing internal body structures and functions. A **contrast medium** is a substance that makes internal organs denser and blocks the passage of X-rays to the photographic film. Introducing contrast media into certain structures or areas of the body can provide a clearer image of organs and tissues and an indication of how well they are functioning. Contrast media include gases (air, oxygen, or carbon dioxide); heavy metal salts (barium sulfate or bismuth carbonate); paramagnetic compounds (substances that are attracted to a magnetic field), which are used for MRI contrast (gadolinium); and iodine compounds. They can be administered orally, parenterally (for example, intravenously), or by routes that introduce them into an organ or a body cavity (for example, by insertion). Types of diagnostic imaging include X-rays, computed tomography (CT), nuclear medicine, magnetic resonance imaging (MRI), and ultrasound.

Invasive Procedures

Diagnostic tests can be invasive or noninvasive. An **invasive** procedure, such as angiography, requires a radiologist to insert a catheter, wire, or other testing device into a patient's blood vessel or organ through the skin or a body orifice. All invasive tests require surgical aseptic technique. Some procedures, including angiography, are performed in a hospital or same-day surgical facility. The patient may need general anesthesia for some procedures. The anesthetist must closely monitor the patient, who is under anesthesia during and after the test, for life-threatening complications such as anaphylaxis.

Noninvasive Procedures

Noninvasive procedures, such as standard X-rays or ultrasonography, use other technologies to view internal structures.

FIGURE 50-1 A standard X-ray is one of the most frequently performed radiologic tests.

© Steve Hix/Fuse/Getty Images RF

They do not require inserting devices, breaking the skin, or monitoring at the degree needed with invasive procedures.

The most familiar equipment used for diagnostic imaging is the conventional X-ray machine, as shown in Figure 50-1. This machine consists of a table, an X-ray tube, a control panel, and a high-voltage generator. The image produced by a conventional X-ray may be developed on standard X-ray film or captured digitally. Digital radiography is discussed later in the chapter. Other equipment used for diagnostic radiology includes instruments specifically designed for the test. Examples are a mammography unit, a scanner for CT, and a transducer for ultrasound.

► The Medical Assistant's Role in Diagnostic Radiology

LO 50.3

As a medical assistant, you may work with diagnostic radiology in a radiology facility or in a medical office. Your duties in a radiology facility will include assisting a radiologic technologist or a radiologist in performing diagnostic radiologic procedures. Depending on the scope of practice in your state, you may be allowed to learn how to operate certain X-ray equipment. Even if you are not allowed to assist with an X-ray procedure or to operate X-ray equipment, you will probably provide preprocedure and postprocedure patient care. Your duties in an orthopedic office may include assisting a radiologic technologist in performing X-ray procedures. In an obstetric practice, you might assist a physician in performing

an ultrasound examination of a pregnant woman. Even if you work in a medical office that does not perform radiologic testing, you must still provide a certain amount of preprocedure care and education. In order to properly explain a test to a patient and to assist a radiologic technologist or radiologist in performing a test, you must have a basic understanding of X-ray technology. You also may need in-service training to ensure accuracy and patient safety for some procedures. See the *Educating the Patient* feature Providing Patient Instruction for Radiologic Procedures.

Preprocedure Care

Preprocedure care varies somewhat, depending on the test. In general, however, you may do the following:

- Schedule the patient's appointment, if necessary. Inform the patient of the location, date, and time of the procedure.
- Provide preparation instructions. Advise the patient about dietary restrictions or requirements (such as fasting or drinking liquids) as well as medication requirements (such as taking a laxative). Always check with the radiology facility for specific requirements and be sure the patient receives this information.
- Explain the procedure to the patient briefly and clearly. Use proper terminology and nontechnical language. Reinforce the doctor's reason for requesting the procedure and provide any available written information about the test. Inform the patient about the length of the examination, possible side effects or safety precautions and warnings, and injections or uncomfortable steps. Check for clarity and understanding by using the mirroring communication technique when communicating with the patient. You must ensure that the patient understands the preprocedure directions.
- Ask pertinent questions. Obtain a medication history from the patient, because current medications could interfere with some procedures. If the patient is a woman of child-bearing age, ask whether she is pregnant or if there is any chance she could be pregnant. Report the answers to the physician in a medical office or to the radiologic technologist in a radiology facility.

Care During and After the Procedure

If you work in a radiology facility, your responsibilities include preparing and guiding the patient through the procedure. You also may assist the radiologic technologist or the radiologist in performing the procedure by placing, removing, and developing film in the X-ray machine. Procedure 50-1, at the end of this chapter, describes the general process of assisting with a radiologic procedure.

You may care for a patient and assist the radiologic technologist or radiologist during a wide variety of X-ray and other diagnostic imaging tests. While requirements of different procedures vary, you will probably be asked to perform many of the duties described in Procedure 50-1. Although you are unlikely to position the patient, you should know that the position relative to the X-ray source determines the path of the X-rays and the resulting images. Figure 50-2 illustrates common X-ray pathways and the images produced.

Verifying Insurance for Radiologic Procedures

Managed care health insurance plans are the most common type of insurance you will encounter in the office. Patients with HMOs are often required to use the services of certain radiology facilities. Because managed care plans often have facilities with which they are contracted, be sure the patient is sent to a radiology facility that is contracted with his or her health insurance. If needed, verify and complete the necessary referrals for all radiology testing. Make insurance verification a regular step in preprocedure care.

Storing and Filing X-rays

Many X-rays are now stored digitally, but there may be some instances where an actual X-ray film is produced. In this case, you may be responsible for storing X-ray films if you work in

a radiology facility. Follow these guidelines for proper X-ray storage:

- Keep fresh film on hand at all times.
- Maintain new and exposed films in as good a condition as possible by keeping them at a temperature between 50°F and 70°F (between 10°C and 20°C) and a relative humidity between 30% and 50%. Radiology facilities usually have one or more special rooms for films.
- Prevent pressure marks and keep expiration dates visible by storing packages on end; do not stack them on top of each other.
- Use a first-in, first-out method for using film (that is, use the oldest film first).
- Open film packages or boxes only in the darkroom.
- Do not store film near acid or ammonia vapors.

FIGURE 50-2 These are X-ray pathways and resulting projections for the most common types of X-rays. (Images are for instruction only. Patients should have protective lead shields during X-ray procedures.)

EDUCATING THE PATIENT

Providing Patient Instruction for Radiologic Procedures

It is crucial for patients to thoroughly understand the pre- and postprocedural instructions because accurate and focused diagnoses depend on correct radiology images. Provide patient instructions orally, observing for understanding and soliciting feedback from the patient. Follow the oral instructions with written instructions. Review the written instructions and encourage questions to clarify patient understanding. A collection of instructions for common radiologic tests ordered by your facility can be obtained from the radiology facility your facility uses most frequently. Keep a library of patient instructions for a variety of diagnostic procedures.

You also will be responsible for providing accurate record-keeping of X-rays. See Procedure 50-2, at the end of this chapter, for guidelines on documentation and filing techniques.

Remember, X-ray films are the property of the radiology facility or the doctor's office where they are taken. Although the films may be sent (or taken by the patient) to a hospital or another doctor for consultation, they should be returned to the original facility (for example, the radiologist's office). In some facilities, the images are stored on the computer and the patient receives an electronic copy to take to another doctor or medical facility. The information, however, is the patient's property, so the patient need not return reports.

► Common Diagnostic Radiologic Tests

LO 50.4

A variety of radiologic imaging tests are available. Table 50-1 identifies some of the most frequently ordered tests and the disorders they are used to diagnose.

Contrast Media in Diagnostic Tests

Various procedures involve the use of contrast media to see body structures and observe their function. These procedures include angiography, arthrography, barium enema, barium swallow, cholangiography, cholecystography, cystography, fluoroscopy, hepatobiliary (HIDA) scan, intravenous pyelography, magnetic resonance imaging (sometimes), myelography, nuclear medicine studies, and retrograde pyelography.

As mentioned, contrast media can be administered by mouth, by needle or catheter into a blood vessel, or by a route that introduces the medium into an organ or a body cavity (for example, into the colon). A contrast medium can cause adverse effects in some patients. Common adverse effects with oral agents include mild and transient abdominal cramping, constipation, nausea, vomiting, diarrhea, skin rashes, itching, heartburn, dizziness, and headache. Intravenous agents cause some of the same adverse effects, as well as localized injection-site reactions and more serious reactions such as anaphylaxis.

Because many contrast media contain iodine, a common allergen, patients should be questioned about known allergies to iodine or shellfish, which contain iodine, before procedures involving the use of contrast media. All patients should be observed during such procedures for signs of allergic reaction.

Fluoroscopy

X-rays can cause certain chemicals to fluoresce, or emit visible light. When X-rays penetrate a body structure and are directed onto a fluorescent screen, they produce an image the radiologist can view either directly or through special glasses. Usually, a radiologist, rather than a radiology technician or medical assistant, performs fluoroscopic procedures.

Many diagnostic procedures involve fluoroscopy, which allows viewing of internal organ movement or the movement of a contrast medium, such as barium sulfate, while the contrast medium travels through the alimentary canal. Fluoroscopy also guides the radiologist in locating a precise internal area that needs to be recorded on film or digitally.

Fluoroscopic images are sometimes photographed for further study. Photofluorography is a series of these photographs that records the body's internal movements over time. Cine-fluorography is a motion picture of the internal movements of the body.

Hysterosalpingography

Hysterosalpingography, also called uterosalpingography, is a radiologic examination of a woman's uterus and fallopian tubes using fluoroscopy. This procedure is used to examine women who have difficulty becoming pregnant. It is sometimes ordered as part of a fertility exam or when the woman has a history of miscarriages that result from congenital abnormalities of the uterus. It is also used to determine the presence and severity of tumor masses or adhesions, uterine fibroids, and fallopian tube adhesions or obstructions. A hysterosalpingogram (Figure 50-3) assists the radiologist in evaluating the shape and structure of the uterus, the openness (patency) of the fallopian tubes, and any scarring within the fallopian tubes and peritoneal cavity. Hysterosalpingography is usually performed on an outpatient basis.

FIGURE 50-3 A hysterosalpingogram of the uterus and fallopian tubes.

TABLE 50-1 Common Radiologic Tests and Disorders Diagnosed

Test	Disorders Diagnosed/Treated
Angiography	
Cardiovascular	Status of blood flow, collateral circulation, malformed vessels, aneurysms, narrowing or blockages of vessels, and presence of hemorrhage
Cerebral	Aneurysm, hemorrhage, evidence of cerebrovascular accident, and arteriosclerosis
Gastrointestinal (GI)	Upper gastrointestinal bleeding
Pulmonary	Pulmonary emboli (especially when lung scan is inconclusive) and evaluation of pulmonary circulation in some heart conditions before surgery
Renal	Abnormalities of blood vessels in urinary system
Arthrography	Joint conditions
Barium enema (lower GI series)	Obstructions, ulcers, polyps, diverticulosis, tumor, and motility problems of colon or rectum
Barium swallow (upper GI series)	Obstructions, ulcers, polyps, diverticulosis, tumor, and motility problems of esophagus, stomach, duodenum, and small intestine
Cholangiography	Gallstones, gallbladder, or common bile duct stones or obstructions and ability of gallbladder to concentrate and store dye
Computed tomography (CT)	Aortic and heart aneurysms, disorders of liver and biliary systems, renal and pulmonary tumors, brain abnormalities (tumors, blood clots, evidence of cerebrovascular accident, outlines of brain ventricles), GI tract lesions, GI disorders (acute pseudocyst of pancreas, abdominal abscesses, biliary obstruction), breast diseases and disorders, spinal disorders, and to guide biopsy procedures
Fluoroscopy	Structure, process, and function of organs in motion to detect abnormalities
HIDA (hepatobiliary) scan	Diagnosis of structural and functional problems with the liver, gallbladder, and bile ducts
Intravenous pyelography (IVP) (excretory urography)	Urinary system abnormalities, including renal pelvis, ureters, and bladder (for example, kidney stones); abnormal size, shape, or structure of kidneys, ureters, or bladder; space-occupying lesions; pyelonephrosis; hydronephrosis; and trauma to the urinary system
KUB (kidneys, ureters, bladder) radiography	Size, shape, and position of urinary organs; urinary system diseases or disorders; and kidney stones
Magnetic resonance imaging (MRI)	Cancerous tissue, atherosclerotic tissue, blood clots, tumors, and deformities, particularly of the heart valves, brain, spine, and joints
Mammography	Breast tumors and lesions
Myelography	Irregularities or compression of spinal cord
Nuclear medicine (radionuclide imaging)	Abnormal function (defects), lesions, or disorders of bone, brain, lungs, kidneys, liver, pancreas, thyroid, and spleen
Radiation therapy	Treatment of cancer
Retrograde pyelogram	Obstruction of ureters, bladder, or urethra (including tumors, stones, strictures, or blood clots) and perinephritic abscess
Ultrasound	Abnormalities of gallbladder, liver, spleen, heart, kidneys, gonads, blood vessels, lymphatic system, and fetal conditions (including number of fetuses; age and sex of fetus; fetal development, position, and deformities)

Angiography

Angiography is a test used to diagnose abnormalities in blood vessels, including the following:

- Aneurysm—a widening or ballooning of an artery
- Atherosclerotic disease—fatty plaques on the walls of arteries
- Arteriovenous malformations (AVM)—abnormal connections between arteries and veins
- Arterial stenosis—narrowing of an artery

The test is done in one of three ways:

- Catheter angiography with X-rays

- CT angiography
- MRI angiography

Catheter angiography requires a physician (usually a radiologist) to insert a catheter into the patient's vein (venography) or artery (arteriography). The physician first guides the catheter tip to the vessel being examined, then injects a contrast medium through the catheter and takes a series of X-rays to assess the vessel's blood flow and condition (Figure 50-4). The test—used to evaluate the heart vessels (coronary angiography), the brain (cerebral angiography), or the femoral, brachial, or carotid artery—may be performed jointly by a radiologist and a vascular surgeon or other specialist.

FIGURE 50-4 Carotid angiogram: an intra-arterial catheter is inserted and a contrast medium is injected to create an image of the arteries.
© Royalty-Free/CORBIS

Because this procedure requires insertion of a catheter into a blood vessel and the use of local anesthesia, the patient is admitted to a hospital or same-day surgical facility. The physician who performs the examination provides the patient with instructions immediately before the procedure. You will, however, schedule the procedure, and you can encourage the patient to ask questions. Radiology facilities usually have information sheets for each procedure. If the patient has questions you cannot answer or if you have any doubt about preprocedure instructions, check with your supervisor.

CT and MRI angiography (MRA) may be performed with or without contrast medium. The contrast medium is injected into a vein, usually in the arm, and images are made using computer programs that produce detailed images of blood vessels. Because CT and MRI angiography are less invasive than catheter angiography, they are usually performed on an outpatient basis. CT and MRI are discussed in more detail later in the chapter.

Arthrography

Arthrography is performed by a radiologist, who uses a contrast medium and fluoroscopy to help diagnose abnormalities or injuries in the cartilage, tendons, or ligaments of the joints—usually the knee or shoulder. Although MRI is used more often to evaluate soft-tissue injuries in joints, arthrography can provide an image while the patient moves the joint. When preparing patients for arthrography or assisting with the procedure, follow these guidelines:

- Describe the procedure to patients and inform them the examination will take about 1 hour. Ask patients about possible allergies to contrast media, iodine, or shellfish. If they have any of these allergies, inform the radiologist immediately.
- Explain to patients that no special preprocedure preparations are necessary.
- Tell patients the doctor will first inject a local anesthetic to numb the area being examined. Then the doctor will inject the contrast medium (dye, air, or both) into the joint and will use a fluoroscope to evaluate the joint's function. Inform patients who are having a knee examined that the doctor may ask them to walk a few steps to spread the contrast medium.
- After the test is completed, advise patients that for 1 or 2 days they may experience some pain or swelling, particularly if the joint is exercised. Tell them to rest and avoid putting strain on the joint.

Barium Enema (Lower GI Series)

A **barium enema** is performed by a radiologist, who instills barium sulfate through the anus into the rectum and then into the colon, to help diagnose and evaluate obstructions, ulcers, polyps, diverticulosis, tumors, or motility problems of the colon or rectum. This procedure is called a *lower GI (gastrointestinal) series*—a series of X-rays of the colon and rectum. The two types of barium enema techniques are single-contrast, in which only barium is instilled into the colon, and double-contrast, in which air is forced into the colon to distend or inflate the tissue. The air may be added while the barium is present, after it has been expelled, or both. The double-contrast technique makes structures more visible by fluoroscopy and allows identification of small lesions. The digestive tract must be totally empty, requiring the patient to thoroughly cleanse the tract with a series of preparatory steps and to have nothing by mouth for 8 hours before the test, except for one cup of clear liquid on the morning of the test. In most facilities, a radiologic technologist assists with a barium enema, but you may assist the patient before and after the procedure. If you do assist with a barium enema, you will have various responsibilities before, during, and after the procedure.

Before the Procedure Schedule the patient's appointment in the morning so that he can sleep through most of the period during which his digestive tract must be empty and thus avoid experiencing hunger unnecessarily. Include the following items when you instruct a patient about the preparation for a barium enema:

- Describe the procedure and tell the patient the examination will take 1 to 2 hours.
- Ask about possible allergies to contrast media, iodine, or shellfish and report such allergies to the radiologist.
- Explain the importance of following the preparation instructions so that the colon and rectum are free of residual material. Residual material in the colon or rectum could cause blockages or shadows, resulting in an inaccurate test.

- Preprocedure preparation on the day before the examination includes following a clear liquid diet beginning in the morning (coffee, tea, carbonated beverages, clear gelatin, strained fruit juice, bouillon, or clear broths; milk is not permitted) and taking prescribed amounts of electrolyte solution or other laxative preparations and fluids on a specified schedule.
- Tell the patient he may have one cup of coffee, tea, or water on the morning of the examination.

During the Procedure Follow these steps when assisting during a barium enema:

1. Have the patient undress and put on a gown.
2. Tell the patient to expect some discomfort during the examination, as well as frequent side-to-side turning.
3. Have the patient lie on his side. The radiologist inserts the enema tip, designed to help the patient hold the liquid, into the rectum and instills the barium sulfate into the colon. If the patient experiences cramping or the urge to defecate during instillation of the barium, instruct him to relax the abdominal muscles by breathing slowly and deeply through the mouth.
4. Instruct the patient to remain still and hold his breath when X-rays are taken. Using a fluoroscope, the doctor observes the barium as it flows through the lower bowel and periodically takes X-rays while the patient is placed in various positions. You may be asked to assist with placing the patient in these positions.
5. If a double-contrast study is being performed, tell the patient that air will be introduced into the colon to expand the colon tissue. Explain that the combination of air and barium provides a clearer view of structures than only one contrast medium would provide and allows possible identification of small lesions if they are present.
6. When the doctor has completed the barium portion of the examination, including X-rays with both barium and air, tell the patient to use the toilet and expel as much barium as possible. Explain that if enough barium is expelled, the doctor may take a final X-ray of the empty colon.
7. Have the patient wait to dress until the doctor tells you that no additional X-rays are needed.

After the Procedure After the radiologist has completed the barium enema, instruct the patient in postprocedure care. Tell the patient the following:

- He may now have a regular meal.
- The residual barium may make his stools appear whitish or lighter than usual, but this is normal.
- The barium may cause constipation, so he should drink extra water to help relieve constipation and to eliminate the remaining barium sulfate. The physician may order a laxative to be taken if constipation is not relieved within 1 or 2 days.

Barium Swallow (Upper GI Series)

A **barium swallow** involves oral administration of a barium sulfate drink to help diagnose and evaluate obstructions,

ulcers, polyps, diverticulosis, tumors, or motility problems of the esophagus, stomach, duodenum, and small intestine. This test is called an *upper GI series*. In preparation for this test, the patient can have nothing by mouth for at least 8 hours before the test. You will have various responsibilities before, during, and after the procedure.

Before the Procedure Schedule the patient's appointment in the morning so that she can sleep through most of the period during which her digestive tract is empty and thus avoid experiencing hunger unnecessarily. When instructing a patient about the preparation for an upper GI series, include the following items:

- Describe the procedure and tell the patient the examination will take about 1 hour. If X-rays of the small bowel are needed, the test may take several hours.
- Ask about possible allergies to contrast media, iodine, or shellfish and report such allergies to the radiologist.
- Explain the importance of following the preparation instructions so that the stomach is empty. Preprocedure requirements include having nothing by mouth (food or liquids) after midnight the night before and no breakfast the morning of the examination. If the patient's small bowel is to be evaluated, also tell her to take the prescribed laxative preparation between 2:00 and 4:00 p.m. the day before the examination.
- Instruct the patient not to swallow water when brushing her teeth or rinsing her mouth and, if applicable, to stop smoking because nicotine stimulates gastric secretions and can affect the test results.

During the Procedure When assisting during an upper GI series, take the following steps:

1. Have the patient undress and put on a gown.
2. Explain that she will be drinking a barium sulfate drink that tastes chalky and resembles a milk shake.
3. Have the patient stand and drink part of the barium.
4. The radiologist will use a fluoroscope to observe the flow of the barium and to assess the functioning of the esophagus, stomach, duodenum, and small intestine as the barium passes through the structures. (The doctor will then direct the patient to drink additional barium and continue to observe the function of the various structures.)
5. Place the patient on the X-ray table and move her into different positions (if medical assistants are permitted to do so in your state), as instructed by the doctor, to allow X-rays to be taken of the upper digestive tract. Instruct the patient to remain still and hold her breath when X-rays are taken.

After the Procedure After the physician completes the upper GI series, instruct the patient in postprocedure care. Give the patient the following information:

- She may now have a regular meal.
- Her stools may appear whitish or lighter than usual as the barium is eliminated, but this is normal.

- Sometimes, another examination is required after 24 hours to determine whether the barium has moved into the large intestine. If this test is indicated, tell the patient to follow a clear liquid diet (coffee, tea, carbonated beverages, clear gelatin, strained fruit juices, bouillon, or clear broths; milk is not permitted) and to return in 24 hours.

Cholangiography

Cholangiography is performed by a radiologist to evaluate the function of the bile ducts. It involves injection of the contrast medium directly into the common bile duct (during gallbladder surgery) or through a T tube (after gallbladder surgery or during radiologic testing). X-rays or MRIs are taken immediately after injection. Instruct the patient as follows:

- Describe the procedure to the patient and tell him the examination will take about 2 to 3 hours. Ask the patient about possible allergies to contrast media, iodine, or shellfish and report them to the radiologist.
- Explain the preparation instructions. Tell the patient to eat a light evening meal the night before the examination, to take a laxative (as prescribed by the doctor), and to have no food or liquids after midnight. He also should have no solid food the morning of the examination.

Computed Tomography (CT)

Computed tomography (CT) scans are produced by a specialized X-ray camera that rotates completely around the patient and a computer that compiles one cross-sectional view from each rotation of the camera. The patient is lying on a table that gradually moves through the doughnut-shaped machine containing the rotating camera. Cross-sectional images can be reconfigured by a computer program into different planes (frontal, transverse, and sagittal), creating images that give different views of the same area. The images can also be combined to create three-dimensional images.

CT scans are used to diagnose abnormalities in almost all body structures, including the head, kidneys, heart, chest, liver, biliary tract, pancreas, GI tract, spine, pelvis, bones, and breast. Abnormalities and disorders that can be detected using CT scans include the following:

- Cancer
- Injuries from trauma
- Spinal injury
- Pulmonary embolism (blood clot in the vessels of the lung)
- Aortic aneurysm
- Skeletal injuries and abnormalities

When preparing the patient for a CT scan,

- Ask the patient about possible allergies to contrast media, iodine, or shellfish and report them to the radiologist.
- Tell the patient he will be placed on a table that moves through the scanner but he will be able to see around the room during the test.
- Inform the patient that the procedure will last about 45 to 90 minutes and that he must lie still while the scans are taken.

- If a contrast medium will be used, advise the patient that it will be injected into a vein in the arm or on the back of the hand (except with a CT scan of the spine) to enhance detail of the structure being evaluated.
- If the patient is having a CT scan of the head, chest, abdomen, or pelvis, instruct him not to eat anything for 4 hours or drink any liquids for 2 hours before the examination. Explain that he may experience mild nausea after injection of the contrast medium if the stomach is too full.
- Tell the patient to remove metallic objects that could interfere with the path of the X-rays. Also, ask if the patient has skin staples or metallic prostheses that could interfere.
- Inform the patient that a written report of the results should be available within 24 hours of the test and that a report will be sent to his primary care physician (or the referring physician).

Intravenous Pyelography

Also known as *excretory urography*, **intravenous pyelography (IVP)** is performed by a radiologist who injects a contrast medium into a vein. The doctor then takes a series of X-rays as the contrast medium travels through the kidneys, ureters, and bladder. IVP is used to evaluate urinary system abnormalities or trauma to the urinary system. In most facilities, a radiologic technologist assists with IVP, but you may assist the patient before the procedure. If you assist with IVP, you will have several responsibilities both before and during the procedure.

Before the Procedure Schedule the patient's appointment in the morning so that she can sleep through most of the period during which her digestive tract is empty and thus avoid experiencing hunger unnecessarily. When instructing a patient about the preparation for an IVP, include the following information:

- Describe the procedure and tell the patient the examination will take about 1½ hours.
- Ask the patient about possible allergies to contrast media, iodine, or shellfish and report such allergies to the radiologist.
- Explain the importance of adhering to the preparation instructions so that the bowel is free of any material that could obstruct the view of the urinary organs.
- Tell the patient to follow a liquid diet (coffee, tea, carbonated beverages, clear gelatin, strained fruit juice, bouillon, or clear broths, but no milk) the day before the examination. The patient may be given a laxative preparation to take the night before the examination.
- No food or liquids are allowed after midnight and no breakfast the morning of the examination. Some physicians also order an enema to be taken about 2 hours before the examination.

During and After the Procedure When assisting during an IVP, you will generally proceed in this manner:

1. Have the patient undress and put on a gown.
2. Explain that a contrast medium will be injected into her vein (usually in the arm). Instruct her to inform the physician if she notices shortness of breath or itching after injection of the dye because this can indicate an allergic reaction.

3. Have the patient lie on the X-ray table and move her into different positions, as instructed by the physician, to allow X-rays to be taken of the urinary tract as the contrast medium is excreted. Instruct the patient to remain still and hold her breath when X-rays are taken.
4. Note that some physicians place a compression device on the abdomen, which helps hold the contrast medium in the kidneys and ureters by exerting moderate pressure.
5. After the physician takes the series of X-rays to evaluate urinary system function, ask the patient to urinate, and explain that a final X-ray will be taken.
6. Inform the patient that she may resume a normal diet after the test and that the contrast medium will be eliminated in the urine.

Retrograde Pyelography

Retrograde pyelography is similar to the IVP, except that the doctor injects the contrast medium through a urethral catheter. This procedure, which evaluates function of the ureters, bladder, and urethra, is often used for patients with poor kidney function. Follow the same preparation and assistance instructions as for the IVP.

Kidneys, Ureters, and Bladder (KUB) Radiography

Also called a *flat plate of the abdomen*, **KUB radiography** is an X-ray of the abdomen used to assess the size, shape, and position of the urinary organs; to evaluate urinary system diseases or disorders; and to determine the presence of kidney stones. It also can be helpful in determining the position of an intrauterine device (IUD) or in locating foreign bodies in the digestive tract. No patient preparation is required. A radiologic technologist takes a KUB X-ray; thus, you follow the guidelines you would use for a patient having any type of standard, noninvasive X-ray.

Magnetic Resonance Imaging (MRI)

Magnetic resonance imaging (MRI) uses a strong magnetic field and radio frequency signals in combination with a computer to allow the physician to examine internal structures and soft tissues. The combination of nonionizing (radio frequency) radiation and a magnetic field allows the MRI scanner to produce images based primarily on the water content of tissues, making MRI a useful imaging tool for soft tissues. Because no ionizing radiation (X-ray) is used to produce the image, the risk of harmful effects to the patient is very low. The test may be performed with or without contrast. You will be responsible for preparing the patient for an MRI and assisting with the procedure.

Before the Procedure When instructing a patient about preparing for an MRI, include the following steps:

- If a contrast medium is going to be used, ask the patient and inform the radiologist about possible allergies to contrast media, iodine, or shellfish.
- Screen the patient to determine whether any internal metallic materials are present. (This is especially important

because a strong magnetic field is involved in creating the image.) Ask about a pacemaker, brain or aneurysm clips, brain or heart surgery, shunts and heart valves, other surgeries, and shrapnel or metal fragments (particularly in an eye).

- Ask the patient whether he is or has been a metalworker. If so, he may carry metal slivers, chips, or filings under his nails or skin.
- Instruct women not to wear eye makeup the day of the examination, as it often contains metallic ingredients.
- Describe the procedure to the patient and explain that the examination will take between 45 minutes and 2 hours.
- Inform the patient that he may wear street clothing during the test but to avoid wearing clothing with metallic thread, metal stays or grippers, or thick elastic. Tell the patient that depending upon the location to be examined he could be asked to undress and put on a gown.
- Tell the patient he does not need to fast before the examination or follow any prepcedure diet, unless he is having an MRI of the pelvis. In that case, instruct him to have no solid food for 6 hours and no liquids for 4 hours before the examination. Inform the patient that he may take prescription medications.
- Explain that he will not be required to drink an oral contrast preparation but should avoid caffeine for 4 hours before the examination. Tell the patient he will probably have no side effects from the examination but that some nausea may occur as a result of the contrast medium.

During and After the Procedure When assisting during an MRI, you will need to follow these specific steps:

1. Have the patient lie on the padded table.
2. Explain that the table will be placed inside a long, narrow tube about 22 inches in diameter and that he will hear a loud knocking noise as the machine scans. Offer the patient hearing protection devices (ear plugs or headphones) during the test. Warn the patient to remain still to avoid blurring the image and the consequent need for a retake. Note that physicians may order sedation for patients who are claustrophobic or cannot lie still for a long period (Figure 50-5).
3. Advise the patient that although the technician will not be in the scanning room during the examination, she will maintain contact with a camera and a microphone. The patient may speak to the technician at any time in case of a problem, but he is encouraged to be still for each series.
4. Inform the patient that his primary care physician or referring doctor should have a preliminary report of test results within about 24 hours.

Mammography

Mammography, the X-ray exam of the internal breast tissues, helps in diagnosing breast abnormalities (Figure 50-6). A specially trained radiologic technologist takes mammograms.

You will have several responsibilities during both setup and patient care before and after mammography. However,

FIGURE 50-5 A patient who is claustrophobic or unable to lie still may require sedation during an MRI.

© UpperCut Images/SuperStock RF

a medical assistant does not assist during mammography in most states. Instead, you will prepare the patient for the procedure and ease her fears. For more information regarding patient education before a mammogram, see the *Assisting in Reproductive and Urinary Specialties* chapter.

Stereotactic Breast Biopsy

When a mammogram reveals an abnormality in the breast tissue, the physician may want a biopsy to determine if it is malignant. Because so many abnormalities revealed by mammography are benign and present no health risk, physicians now perform *stereotactic breast biopsies*, which are less painful and less invasive than conventional excisional biopsies. The procedure is performed by a physician and a radiologic technologist and is similar to mammography, except that the patient is usually lying face down or sitting rather than

FIGURE 50-6 Mammograms can reveal the presence of tumors that are not detected by other means. The mammogram on the right indicates normal breast tissue, whereas the one on the left suggests a malignancy.

© UHB Trust/Stone/Getty Images

standing. The breast is compressed with a compression paddle to confirm that the area of the breast with the lesion is correctly centered in the paddle window. X-rays are taken of the breast from two different angles. A computer is used to help determine the exact positioning of the biopsy needle and the physician uses a needle to take a small sample of tissue for examination by a pathologist. The attending physician later contacts the patient with the test results.

Myelography

Although MRI is used more often to evaluate the spinal cord and spinal nerves, **myelography** is a kind of fluoroscopy of the spinal cord used when MRI is not practical—if a patient has a pacemaker or other medical device that prevents the patient from undergoing MRI. The physician performs a lumbar puncture, removes some cerebrospinal fluid (CSF), and instills a contrast medium to evaluate spinal abnormalities, such as compression of the spinal cord. Sometimes the physician performs pneumoencephalography, which involves instilling air after removal of the CSF to allow viewing of the cerebral cavities.

The physician who performs myelography or pneumoencephalography must be skilled in performing lumbar puncture—most likely a radiologist, neurologist, neurosurgeon, or anesthesiologist. A radiologic technologist is typically the only other person present for the test. Although myelography is not used as frequently as it was before the invention of CT and MRI, it is still performed when these newer techniques do not provide enough information about the spinal canal. Myelography may be reserved for cases in which the clinical findings are unusual or the scanning results uncertain.

Nuclear Medicine

Also known as *radionuclide imaging*, **nuclear medicine** involves the use of radionuclides, or radioisotopes (radioactive elements or their compounds). The radionuclides are administered orally, intravenously, or through routes that introduce them into organs or body cavities. The purpose is to evaluate the bone, brain, lungs, kidneys, liver, pancreas, thyroid, or spleen. Sometimes, the entire body is scanned for “hot spots,” or places where the radioisotope is concentrated.

For common nuclear medicine scans, the technician uses a scanner called a *gamma camera*. This scanner detects radiation from the radioisotope and converts it into an image (called a *scintiscan* or *scintigram*) to be photographed or displayed on a screen (see Figure 50-7). Some images are produced immediately, whereas others take up to several days. Radionuclide imaging exposes patients to lower doses of radiation than some radiologic techniques because the amount of ionizing radiation in the isotope is less than that emitted from X-ray cameras. Other nuclear medicine procedures include single photon emission computed tomography (SPECT), positron emission tomography (PET), and MUGA (multiple gated acquisition) scan.

- **SPECT** is often used to locate and determine the extent of brain damage from a stroke. The gamma camera detects signals induced by gamma radiation and a computer converts these signals into either two- or three-dimensional images that are displayed on a screen.

FIGURE 50-7 This bone scan shows the uptake of the radioactive contrast medium.

© Jim Wehtje/Getty Images RF

- **PET** entails injecting isotopes combined with other substances involved in metabolic activity, like glucose. These special isotopes emit positrons, which a computer processes and displays on a screen. PET is especially useful for diagnosing brain-related conditions like epilepsy, mental illnesses, and Parkinson's disease.
- **MUGA scan (nuclear ventriculography)**—evaluates the condition of the heart's myocardium. It can be done while the patient is at rest or in stress (exercise) and involves the injection of radioisotopes that concentrate in the myocardium. The gamma camera allows the physician to measure ventricular contractions to evaluate the patient's heart wall.

When preparing a patient for a nuclear medicine procedure, describe the procedure and explain how long it will take. Also, explain any preparation requirements and other special instructions and tell the patient she will need to wait the required length of time for the uptake of the radioisotope. Length of examination and requirements for common scans are as follows:

- A bone scan lasts about 1 hour; it is done 2 to 3 hours after a 15-minute injection; the patient drinks 1 quart of liquid between the injection and the scan; a normal diet is permitted.
- A liver/spleen or lung scan lasts approximately 1 hour; there are no dietary restrictions.
- A kidney scan lasts about 2 hours; there are no dietary restrictions.

- A thyroid uptake and scan test usually requires 2 days; the patient takes a capsule of contrast medium in the morning and has the scan on the first day; the patient returns 24 hours later for the second scan; there are no dietary restrictions, except the patient must have no fish because of its natural iodine content.

Ultrasound

Ultrasound directs high-frequency sound waves through the skin over the area of the body being examined and produces an image based on the echoes created by the sound waves bouncing off of body structures. A radiologist or an ultrasound sonographer coats the body area with a special gel and passes a transducer (instrument similar to a microphone) over the area. As the transducer passes back and forth, it picks up echoes from the sound waves, which a computer converts into an image—sometimes called a sonogram—on a screen. Ultrasound is used to detect abnormalities in the gallbladder, liver, spleen, heart, and kidneys. It is also safe to use in obstetrics to evaluate the developing fetus or to detect multiple fetuses because it does not expose the patient (or the fetus) to radiation (Figure 50-8). In this case, the obstetrician may perform the test in the office.

One form of ultrasound—Doppler echocardiography—involves sound waves that echo against the flow of blood through vessels. Doppler echocardiography is usually performed by a cardiologist to determine whether blood flow is laminar (normal) or turbulent (disturbed).

Echocardiography, a type of ultrasound test, is used to study the structure and function of the heart. The test is usually performed while the patient is resting and again after exercising on a treadmill or bicycle. Images of the heart before and after exercise help the physician diagnose abnormalities of the structure and function of the heart and heart valves.

When preparing the patient for an ultrasound or assisting with the examination, follow these guidelines:

FIGURE 50-8 Ultrasound is commonly used to evaluate the health of a developing fetus.

© UHB Trust/Stone/Getty Images

- Describe the procedure to the patient and inform her that the examination will take about 1½ to 2 hours, depending on the type of ultrasound. For example, a cardiac ultrasound takes about 1½ hours; pelvic, 1 to 2 hours; and abdominal, ½ to 1 hour.
- Explain the preparation requirements, which vary according to the type of ultrasound. Tell a patient who is having a gallbladder or liver ultrasound not to eat for several hours before the test. Tell a pregnant patient to drink the prescribed amount of water 1 hour before the examination and not to void. Advise a patient having a pelvic ultrasound to take the prescribed laxative (if indicated), drink three to four glasses of water within 1 hour, and not to void within 1 hour of the test. If the patient is having an abdominal ultrasound, instruct her to take a laxative the night before the examination and not to have any food or fluids for 8 hours before the test.
- Advise the patient to wear loose, easy-to-remove clothing.

Dual-Energy X-ray Absorptiometry (DXA)

Dual-energy X-ray absorptiometry (DXA), often called bone densitometry, is a screening test that uses small doses of X-rays to determine the mineral density of a person's bones. The test may be used to diagnose osteoporosis or to monitor treatment of osteoporosis or other conditions that cause bone loss after diagnosis. Patients who take medications known to cause bone loss, such as Dilantin®, corticosteroids, and some barbiturates, should be screened for bone loss using DXA. Bone densitometry is also recommended for people with the following conditions:

- Postmenopausal women
- Smokers
- Hyperthyroidism
- Hyperparathyroidism
- Type 1 diabetes
- Kidney disease
- Recurrent fractures

During the test, the patient will lie on a padded table while very low-dose radiation is generated below the table and detected with a specialized arm that passes over the patient. The patient must lie very still while the test is being performed. DXA is usually completed within 30 minutes.

When instructing patients preparing for a DXA, tell them to wear loose-fitting clothing that does not have zippers, metal buttons, or belts. Patients will be asked to remove wallets, keys, or jewelry in the area being scanned. Tell patients they should avoid taking calcium supplements 24 hours before the test. A patient who has recently had X-rays or CT scans using a contrast medium such as barium may need to wait 2 weeks after the contrast before having a DXA scan.

The test is most often read by a radiologist; however, rheumatologists and endocrinologists can also read DXA scans. The report includes two results: the T score and the Z score. The T score is a measure of the amount of bone the person has compared to that of young adults. This number is used

to assess risk of bone fractures. The Z score is the amount of bone the patient has compared to people of the same race, gender, age, and size. If the Z score test is high or low, additional medical tests for other underlying conditions, such as hyperparathyroidism, may be needed.

► Common Therapeutic Uses of Radiation

LO 50.5

Used therapeutically, radiology is called **radiation therapy**, which is used to treat cancer by preventing cellular reproduction. The two types of radiation therapy are teletherapy and brachytherapy. **Teletherapy**, also called external beam radiotherapy, is the most common form of radiation therapy and is done on an outpatient basis. It allows deep penetration of tissues and is used primarily for deep tumors. The patient experiences minimal side effects, which may include a “sunburn” effect at the treatment site, mild swelling and tenderness, and sometimes mild fatigue. Generally, the superficial tissues are not permanently damaged.

Stereotactic radiosurgery is a type of teletherapy that uses CT or MRI scanning in conjunction with radiation to treat brain tumors, acoustic neuromas, and arteriovenous malformations—defects in connections between arteries and veins—deep in the brain. In some cases, liver, prostate, and lung tumors are also treated with stereotactic radiosurgery. This method allows for very precise delivery of radiation to areas of the brain or other organs that are normally inaccessible with traditional surgical techniques, helping spare precious healthy tissue while still treating the tumor.

For a patient having stereotactic radiosurgery for brain tumors, first a neurosurgeon temporarily fastens a stereotactic frame to the patient's head using local anesthesia. The frame helps guide the physician to precisely locate the treatment. A CT or MRI scan is then performed to locate the tumor or malformation. Once the frame is in place and the imaging scan is complete, a radiation oncologist and a neurosurgeon plan the patient's treatment. The patient undergoes treatment based on this plan, has the stereotactic frame removed, and, in most cases, can go home the same day.

Localized cancers are treated with **brachytherapy**. In this technique, the radiologist places temporary radioactive implants close to or directly into cancerous tissue. This technique limits radiation exposure to healthy tissue, targeting only the area where the tumor is located. During brachytherapy, both the staff and the patient are subject to radiation exposure, so radiation safety precautions must be closely followed. When preparing the patient for radiation therapy, follow these guidelines:

- Describe the procedure and explain how long it will take, as determined by the radiologist and oncologist according to the patient's diagnosis and condition.
- Encourage patients to tell the physician about all medications, vitamins, or supplements they are taking.
- Inform the patient that the radiologist or oncologist will explain the treatment's possible side effects. Common

side effects include nausea, vomiting, hair loss, ulceration of mucous membranes, weakness, and malaise. Other possible effects include localized burns on tissue and damage to organs in the treatment path. Encourage the patient to discuss with the doctor (or the oncology nurse specialist) measures to relieve or minimize stress and discomfort.

- Advise the patient to immediately report any other symptoms to the doctor.
- Encourage the patient to get plenty of rest, eat a balanced diet, and drink plenty of fluids.

► Radiation Safety and Dose LO 50.6

For many years after the X-ray's discovery, the seriousness of radiation hazards was not addressed. In the 1920s, the government of Great Britain took the first steps to limit X-ray exposure. Since World War II, studies have been performed, mostly on the effects of high-dose radiation.

Other studies on the effects of background radiation and nonradiologic versus radiologic (X-ray-related) risks have enabled scientists to assess diagnostic X-ray risks. Results from these studies show the risk of excess radiation from routine X-rays to be minimal.

Reducing Patient Exposure

Advances in diagnostic imaging technology, and limits to radiation exposure, have helped reduce the dose of radiation to which a patient is exposed during a diagnostic procedure. Another way to reduce excessive radiation exposure risk lies with the physician, who must assess the benefit-to-risk ratio when recommending a diagnostic radiology procedure. Because radiation has a cumulative effect, the physician must have valid medical reasons for ordering the test, particularly if the patient has recently had other X-rays. Some types of X-rays, such as mammograms, should be repeated regularly, however, because of their potential to prevent or promote treatment of life-threatening disorders.

According to a 1993 report by the National Council on Radiation Protection and Measurements (NCRP), titled *Limitation of Exposure to Ionizing Radiation*, one of the earliest pieces of legislation in the United States to limit occupational radiation exposure was enacted in the 1930s. The first legislation to limit public exposure, however, was not enacted until the 1950s. The 1993 NCRP report set guidelines for protection from radiation in and out of the workplace. The two primary objectives outlined in the report are to prevent serious general tissue damage from radiation by limiting radiation dose to levels below known thresholds for such damage and to reduce the risk of cancer and genetic effects to a level balanced by potential benefits to the individual and society.

Because radiation exposure always poses some degree of risk, the NCRP recommends that any activity involving radiation exposure be justified, or balanced against the expected benefits to society. Furthermore, the NCRP recommends the cost, or detriment, to society from such activities be kept as

low as reasonably achievable (ALARA) and that individual dose limits be applied to ensure that justification and ALARA principles do not result in unacceptable risk levels for individuals or groups.

The NCRP has developed detailed lists on radiation doses to achieve the primary objectives stated in the report. Separate specific limits exist for occupational and public exposure.

Safety Precautions

Understanding and following standard safety precautions are crucial for protection from radiation exposure and are essential to the health and safety of both medical personnel and patients.

Personnel Safety If you work in a medical facility that performs radiologic tests, you are at risk for excessive radiation exposure. To protect yourself from exposure, you must adhere to the following guidelines:

- You (and other members of the medical staff) must always wear a radiation exposure badge, or dosimeter, which is a sensitized piece of film in a holder (Figure 50-9). You must have the badge checked regularly by specially qualified personnel, who measure the degree of radiation uptake on the film to determine the amount of radiation to which you have been exposed.
- Make sure all equipment is in good working order and is checked routinely for radiation leakage and any other problems.
- Be aware that the technician and any other staff members present when equipment is operating should always wear a garment that contains a lead shield.

Patient Safety You must follow all rules governing patient safety from radiation exposure. The *Educating the Patient* section explains safety measures and information that help protect a patient from exposure to unnecessary radiation.

FIGURE 50-9 A radiation exposure badge contains a film that registers the levels of radiation to which a medical staff member is exposed at work.

EDUCATING THE PATIENT

Safety with X-rays

You are responsible for teaching the patient about X-ray safety. In this role, you will need to obtain pertinent patient history data, answer questions, and provide basic information on X-rays, possible side effects, and other important guidelines. Consider the following points when teaching the patient about X-ray safety.

Patient History

- Ask the patient about X-rays received in the past, including how many and what type, and about the possibility of exposure to radiation in the home, school, or workplace. Explain that the effects of radiation exposure are cumulative; that is, the effects are related to total exposure over the lifetime as well as to exposure from each procedure.
- Ask a female patient about the possibility of pregnancy. Use the 10-day rule—take an X-ray only within 10 days of the last menstrual period to avoid taking an X-ray of a patient who is unknowingly pregnant. If the patient knows she is pregnant, do not schedule an X-ray unless approved by the radiologist.
- Inform the patient about possible radiation exposure side effects, which include fetal abnormality or genetic mutation in a fetus (when a patient is pregnant) and the depression of bone marrow activity, which decreases the production of red blood cells and white blood cells.

Patient Questions

- Always answer questions in simple, easy-to-understand language; make explanations brief and clear. Do not use complex medical terms; however, do include proper terminology. Offer written information about the test, if available.
- Answer fully any questions about examinations, including descriptions of procedures; the doctor's reason for ordering them; their length, side effects, injections, or other uncomfortable aspects; preprocedure requirements; cost and insurance issues; and availability of test results.
- Help reduce the patient's fear or anxiety surrounding the scheduled test and help her feel comfortable and informed about the procedure.

General X-ray Information

- Be aware of the most current guidelines established by the American College of Radiology. Always keep up with new studies on radiation exposure risks.

- Encourage the patient to ask questions about the need for X-rays ordered by the doctor and risks associated with those X-rays.
- If the patient's employer requires annual X-rays or a potential employer asks for preemployment X-rays, advise the patient to question the necessity of these tests. Suggest that the patient find out whether the doctor has submittable X-rays on file.
- Advise the patient to discuss testing options with the doctor. For instance, if the doctor orders fluoroscopy, the patient might ask whether standard X-rays can be taken instead, as fluoroscopy, and often mobile X-ray exams, usually carry a higher radiation exposure risk than standard X-rays. Advise the patient to ask questions about X-ray safety standards in the office or hospital in which the tests are to take place.
- Tell the patient to avoid dental X-rays performed with wide-beamed plastic cones; narrow-beamed cones are more exact and less dangerous. In addition, educate the patient about the opinions of the American Dental Association and the National Conference of Dental Radiology, both of which believe X-rays should not be performed solely for insurance claim purposes. Advise the patient to always ask for a lead apron over organs not being studied. Tell the patient to avoid retakes of X-rays because of blurriness or shadows (which are caused by movements or breathing) by remaining still when instructed to do so during X-ray exams.
- Explain the importance of X-rays in proper diagnosis of disorders. Inform the patient about the constant improvements in equipment and X-ray procedures and the much lower doses of radiation now used in these procedures.
- Advise the patient to keep a family record of X-ray exams.
- Educate a female patient without breast disease on the correct schedule for mammography exams. The patient should have a baseline mammogram between ages 35 and 40; a mammogram every 1 to 2 years between ages 40 and 49; and an annual mammogram after age 50.
- Also, tell the patient to see a doctor immediately if she notices a breast mass, lump, or nipple discharge.

► Electronic Medicine

LO 50.7

Recent major advances in telemedicine technology, including rapid video and computer-based communications of medical information, enable physicians to “examine” a patient in

another city or country, view highly detailed medical images, consult with specialists in other cities, and supervise complex medical procedures. In addition, healthcare personnel, including medical assistants, can participate in interactive teaching conferences by means of closed-circuit television.

In some cities, emergency medical technicians (EMTs) can transmit an electrocardiogram (ECG) electronically to an emergency room physician to obtain life-saving directives from the physician. These directives may involve administration of drugs or other measures the EMTs would not be permitted to perform without a physician's order. Similarly, cardiologists monitor some patients by the transmission of daily ECGs through telephone lines to the cardiologist's office.

Digital Imaging and the EHR

With the emergence of electronic health records (EHR), technology in healthcare is expanding rapidly. However, no department is affected more than radiology because it is the only completely technology-driven specialty. Digital radiology (DR) devices are integrated with the EHR system to provide quality images and rapid access and to eliminate the time and equipment associated with film processing and development (Figure 50-10).

Digital Radiography

Conventional, film-based radiography is quickly being replaced by digital imaging techniques. Digital radiography uses a digital reader to “capture” or digitize the X-ray image instead of exposing traditional film (Figure 50-11). Using digital radiography has several advantages, including:

- Better image consistency and quality
- Faster results
- Decreased radiation to patient
- Easier X-ray file sharing
- Simpler storage
- Environmentally safer (producing the image requires no chemicals)

Digital Imaging and Communications (DICOM)

in Medicine Digital Imaging and Communications is a communications protocol or standard for handling, storing,

FIGURE 50-10 A digital sagittal MRI image of the brain.

© Royalty-Free/CORBIS

FIGURE 50-11 A digital bone scan of the neck and skull showing malignant tumors.

© SPL/Science Source

printing, and transmitting information in medical imaging. DICOM was designed as part of the Integrating the Healthcare Enterprise (IHE) initiative that makes it easier for medical systems to share information. A Picture Archive and Communication System (PAC) is the digital storage area where digital images are sent and stored for diagnostic viewing and electronic image storage and distribution.

Advances in Radiology

As radiology continues to experience technological changes, more advances are occurring to enhance digital imaging quality. Some major advances include 3D/4D ultrasound, which provides “live-action” images that allow physicians to observe fetal movement, study body organs, and guide needle biopsies (Figure 50-12).

FIGURE 50-12 A 3D ultrasound shows the fetus in great detail.

PROCEDURE 50-1 Assisting with an X-ray Examination

WORK // DOC

Procedure Goal: To assist with a radiologic procedure under the supervision of a radiologic technologist

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue. You must wear a radiation exposure badge (dosimeter), however, and will be required to wear a garment containing a lead or approved nonlead shield if you remain in the room during the operation of X-ray equipment.

Materials: Patient chart/progress note, X-ray examination order, X-ray machine, X-ray film and holder, X-ray film developer, drape, and patient shield

Method:

1. Check the X-ray examination order and equipment needed.
2. Identify the patient and introduce yourself.
3. Determine whether the patient has complied with the preprocedure instructions. Do not depend on the patient to inform you, but ask the patient if and how he prepped for the procedure.

RATIONALE: *If a patient has not been compliant with preprocedural directions, then the test ordered may not be as effective as it should and will need to be rescheduled.*

4. Explain the procedure and the purpose of the examination to the patient.
5. Instruct the patient to remove clothing and all metals (including jewelry) as needed, according to the body area to be examined, and to put on a gown. Explain that metals may interfere with the image. Ask whether the patient has any surgical metal or a pacemaker and report this information to the radiologic technologist. Leave the room to ensure patient privacy.

Note: Steps 6 through 11 are nearly always performed by a radiologic technologist.

6. Position the patient according to the X-ray view ordered.

7. Drape the patient and place the patient shield appropriately.
 8. Instruct the patient about the need to remain still and to hold the breath when requested.
 9. Leave the room or stand behind a lead shield during the exposure.
 10. Ask the patient to assume a comfortable position while the films are developed. Explain that X-rays sometimes must be repeated.
 11. Develop the films.
 12. Determine if the X-ray films are satisfactory by allowing the radiologist to review the films.
- RATIONALE:** *The radiologist may want another film or view.*
13. Instruct the patient to dress and tell the patient when to contact the physician's office for the results.
 14. Label the dry, finished X-ray films; place them in a properly labeled envelope; and file them according to your office's policies.
 15. Record the X-ray examination, along with the final written findings, in the patient's chart (refer to Progress Note).

PROCEDURE 50-2 Documentation and Filing Techniques for X-rays

WORK // DOC

Procedure Goal: To document X-ray information and file X-ray films properly

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: X-ray film(s), patient X-ray record card or book, label, film-filing envelopes, film-filing cabinet, inserts, and a marking pen

Method:

1. Document the patient's X-ray information on the patient record card or in the record book. Include the patient's name, the date, the type of X-ray, and the number of X-rays taken.

X-RAY EXAMINATIONS RECORD					
Patient	Date	Type X-Ray	No. Taken	Referring Doctor	Comments
Jill Cabot	2/16	Chest	4	Wapnir	
M. C. Gaines	2/16	Right knee	8	Wright	
J. Hale	2/19	Right wrist	6	McCarthy	
L. Becker	2/23	Left hip	4	Wright	
R. Bell	2/24	Chest	4	Wapnir	
Donna Lin	2/24	Sinuses	6	Harris	
Jon Carey	2/26	Right hand	2	Cohen	

FIGURE Procedure 50-2 Step 1 Keeping accurate records of patient X-ray information is an important duty of the medical assistant.

2. Verify that the film is properly labeled with the referring doctor's name, the date, and the patient's name. To note corrections or unusual positions or to identify a film that does not include labeling, attach the appropriate label and complete the necessary information. Some facilities also record the name of the radiologist who interpreted the X-ray.

RATIONALE: To reduce the likelihood of misidentifying a patient's X-ray.

3. Place the processed film in a film-filing envelope. File the envelope alphabetically or chronologically (or according to your office's protocol) in the filing cabinet.
4. If you remove an envelope for any reason, put an insert or an "out card" in its place until it is returned to the cabinet.

RATIONALE: Proper filing techniques save time and prevent litigation.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
50.1 Explain what X-rays are and how they are used for diagnostic and therapeutic purposes.	An X-ray is a high-energy electromagnetic wave that travels at the speed of light and can penetrate solid objects. X-rays can be used for diagnosis by producing images of internal body structures. Therapeutically, X-rays are used to treat cancer by preventing cellular reproduction.
50.2 Compare invasive and noninvasive diagnostic procedures.	Invasive procedures require a radiologist to insert a catheter, wire, or other testing device into a patient's blood vessel or organ through the skin or a body orifice. Noninvasive diagnostic procedures do not require inserting devices, breaking the skin, or monitoring at the degree needed with invasive procedures.
50.3 Carry out the medical assistant's role in X-ray and diagnostic radiology testing.	A medical assistant can work directly with a radiology facility to assist the radiologist or technicians in performing diagnostic procedures. Providing preprocedure and postprocedure care are duties a medical assistant can perform in a medical or radiology facility.
50.4 Discuss common diagnostic imaging procedures.	Numerous diagnostic imaging procedures are used in medicine today, including angiography, fluoroscopy, MRI, CT, arthrography, IVP, KUB, mammography, stereotactic breast biopsy, upper and lower GI series, ultrasound, and bone densitometry.
50.5 Describe different types of radiation therapy and how they are used.	The two basic types of radiation therapy are teletherapy and brachytherapy. Teletherapy is also called external beam radiotherapy because an external beam of radiation is used to penetrate deep tumors. Brachytherapy uses temporary radioactive implants positioned close to or directly into cancerous tissue to treat the tumor and spare healthy tissue.
50.6 Explain the risks and safety precautions associated with radiology work.	The greatest risk associated with a radiology facility is the potential for radiation exposure to patients and healthcare workers. To eliminate this risk, certain safety precautions should be followed. These include careful evaluation by the physician to determine the medical necessity of radiology testing, avoidance of X-rays altogether if a patient is pregnant, and the requirement that all personnel who work in a radiology facility wear a dosimeter.

LEARNING OUTCOMES**50.7 Relate the advances in medical imaging to EHR.****KEY POINTS**

Major advances in telemedicine technology, including rapid video and computer-based communications of medical information, enable physicians to “examine” a patient in another city or country, view highly detailed medical images, consult with specialists in other cities, and supervise complex medical procedures. Sharing records, including actual radiographic images, between facilities is easier with the advent of digital radiographic procedures and the electronic health record.

Recall Raja Lautu from the beginning of the chapter. Now that you have read the chapter, answer the following questions regarding her case.

1. What is the difference between brachytherapy and teletherapy?
2. What should you tell Raja to help prepare her for her radiation treatment?

3. What are the advantages of brachytherapy?
4. What instructions will you give Raja to prepare for her screening DXA test?
5. Why should the DXA be completed before the brachytherapy?

E X A M P R E P A R A T I O N Q U E S T I O N S

1. (LO 50.3) Which of the following would the medical assistant *least* likely perform?
 - a. Performing stereotactic breast imaging
 - b. Filing X-rays
 - c. Providing preprocedure instruction for a mammogram
 - d. Advising the patient to report symptoms after radiation treatment
 - e. Assisting with an ultrasound
2. (LO 50.6) A dosimeter is used to
 - a. Prevent radiation exposure
 - b. Measure radiation exposure
 - c. Measure the dose of medicine given during radiation treatments
 - d. Monitor fluctuations in radiation exposure
 - e. Determine how much radiation is needed to obtain an image
3. (LO 50.2) Which of the following is considered invasive?
 - a. Chest X-ray
 - b. Mammogram
 - c. MRI
 - d. Fluoroscopy
 - e. Angiogram
4. (LO 50.4) What organs are evaluated with a KUB?
 - a. Kidneys, ureters, bladder
 - b. Kidneys, urethra, bladder
 - c. Kidneys, ureters, bowels
 - d. Kidneys, urethra, bowels
 - e. Kidneys and urethra for blood
5. (LO 50.3) Which step in the X-ray procedure would *most* likely be performed by a medical assistant?
 - a. Develop the films
 - b. Evaluate the films
 - c. Label the films
 - d. Position the patient
 - e. Set up the X-ray machine
6. (LO 50.2) A substance that makes internal organs denser and blocks the passage of X-rays to the photographic film is a
 - a. Shielding material
 - b. Dosimeter
 - c. Radiolucent medication
 - d. Digital reader
 - e. Contrast medium

7. (LO 50.4) Which of the following is used to detect osteoporosis?
- Angiography
 - DXA
 - MUGA scan
 - Lower GI series
 - IVP
8. (LO 50.4) Hysterosalpingography is used to determine which of the following?
- Position of the kidneys
 - Presence of gallstones
 - Liver abscess
 - Patency of the fallopian tubes
 - Development of the fetus
9. (LO 50.5) Which of the following is used to treat tumors deep in the brain while sparing healthy tissue?
- Stereotactic radiosurgery
 - Chemotherapy
 - MRI
 - Cerebral angiography
 - Paramagnetic contrast
10. (LO 50.1) Wilhelm Konrad Roentgen is credited with discovering
- X-rays
 - Photographic film
 - Radiation therapy
 - Magnetic resonance imaging
 - SPECT scanning

SOFT SKILLS SUCCESS

Recall Raja Lautu from the case study at the beginning of the chapter. While reviewing the patient preparation information for the DXA scan with Raja, you notice she is distracted and looks worried. After you complete the instructions, you ask if she has any questions. Raja tells you that she doesn't understand why she is having the DXA before her brachytherapy and wants to know why she can't wait until they start the treatment for her breast cancer. What should you tell Raja about the timing of the DXA?

to the samples and office medications, but the area is very disorganized. Kaylyn's first task will be to organize and implement an inventory system for the drugs. Kaylyn is concerned about her abilities because she has only been working for BWW Associates for a couple of months.

Keep Kaylyn Haddix, RMA (AMT), in mind as you study the chapter.

There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

LEARNING OUTCOMES

After completing Chapter 51, you will be able to:

- 51.1** Identify the medical assistant's role in pharmacology.
- 51.2** Recognize the five categories of pharmacology and their importance to medication administration.
- 51.3** Differentiate the major drug categories, drug names, and their actions.
- 51.4** Classify over-the-counter (OTC), prescription, and herbal drugs.
- 51.5** Use credible sources to obtain drug information.
- 51.6** Carry out the procedure for registering or renewing a physician with the Drug Enforcement Administration (DEA) for permission to administer, dispense, and prescribe controlled drugs.
- 51.7** Identify the parts of a prescription, including commonly used abbreviations and symbols.
- 51.8** Discuss nonpharmacologic treatments for pain.
- 51.9** Describe how vaccines work in the immune system.

KEY TERMS

administer	opioid

magnetic therapy	toxicology
narcotic	trade name

- I.C.11** Identify the classifications of medications including:
 - (a) indications for use
 - (b) desired effects
 - (c) side effects
 - (d) adverse reactions
- II.C.5** Identify abbreviations and symbols used in calculating medication dosages
- V.P.3** Use medical terminology correctly and pronounced accurately to communicate information to providers and patients
- X.P.5** Perform compliance reporting based on public health statutes
- X.P.6** Report an illegal activity in the healthcare setting following the proper protocol

3. Medical Terminology

- d. Define and use medical abbreviations when appropriate and acceptable

4. Medical Law and Ethics

- f. Comply with federal, state, and local health laws and regulations as they relate to healthcare settings

6. Pharmacology

- a. Identify drug classification, usual dose, side effects, and contraindications of the top most commonly used medications
- c. Prescriptions
 - (1) Identify parts of prescriptions
 - (2) Identify appropriate abbreviations that are accepted in prescription writing
 - (3) Comply with legal aspects of creating prescriptions, including federal and state laws
- d. Properly utilize Physician's Desk Reference (PDR), drug handbook and other drug references to identify a drug's classification, usual dosage, usual side effects, and contraindications
- e. Comply with federal, state, and local health laws and regulations

7. Records Management

- a. Perform basic keyboarding skills (i.e. Microsoft Word, etc.)

8. Administrative Procedures

- a. Gather and process documents

► Introduction

Pharmacology—the science of drugs—is a great responsibility of allied health professionals. Medication mistakes can injure or even cause the death of a patient. Before you administer drugs, it is important to begin with a good working knowledge of the foundations of pharmacology, including how medications work, how they should be taken, and what problems can occur when they are taken. This chapter provides an overview of the role of drugs in ambulatory health-care facilities.

► The Medical Assistant's Role in Pharmacology

LO 51.1

As a medical assistant, you will be expected to have a basic knowledge of medications. This includes knowledge of prescription drugs and over-the-counter (OTC) drugs. Prescription drugs require a licensed practitioner's written order to authorize the dispensing (and, sometimes, administering) of

drugs to a patient. OTC drugs—available in pharmacies and supermarkets—are purchased by people to treat themselves for ailments ranging from arthritis to colds to stomach ulcers. As a medical assistant you will need to

- Ensure that the licensed practitioner is aware of all medications a patient is taking, both prescription and OTC, as well as vitamins and herbal remedies.
- Ask each patient about alcohol and recreational drug use (both past and present).
- Assist in managing and renewing medication prescriptions.
- Educate the patient, using guidelines provided by the licensed practitioner, about the purpose of a drug and how to take the drug for maximum effectiveness and minimum side effects.

As your state and scope of practice permit, you also may be asked to enter medication orders and give drugs to a patient. Safe and effective drug therapy requires additional knowledge and special skills. To handle these important functions, you must understand pharmacologic principles and sources of drug

FIGURE 51-1 A medical assistant may need to be prepared to answer the patient's questions about a drug the doctor is prescribing.

© Jose Luis Pelaez/Getty Images RF

information, be able to read prescriptions accurately, and be prepared to answer basic patient questions (Figure 51-1). You also must adhere to legal requirements and keep accurate records. Additionally, the Centers for Medicare and Medicaid Services (CMS) ruled in September 2012 that credentialed medical assistants may enter medication orders into a computerized order entry system. This is another excellent reason to become a credentialed medical assistant once you complete your program.

► Pharmacology

LO 51.2

A drug is a chemical compound used to prevent, diagnose, or treat a disease or other abnormal condition. The study of drugs is called **pharmacology**. A specialist in pharmacology is called a *pharmacologist*. Included in pharmacology are

- **Pharmacognosy** (the study of characteristics of natural drugs and their sources).
- **Pharmacodynamics** (the study of what drugs do to the body).
- **Pharmacokinetics** (the study of what the body does to drugs).
- **Pharmacotherapeutics** (the study of how drugs are used to treat disease).
- **Toxicology** (the study of poisons or poisonous effects of drugs).

According to the Department of Justice's Drug Enforcement Administration (DEA) guidelines, a doctor **prescribes** a drug when he gives a patient a prescription to be filled by a pharmacy. To **administer** a drug is to give it directly by injection, by mouth, or by any other route that introduces the drug into a patient's body. A healthcare professional **dispenses** a drug by distributing it, in a properly labeled container, to a patient who is directed to use it.

Sources of Drugs (Pharmacognosy)

Many drugs originate as natural products. Other drugs are developed in the chemical laboratory, as chemists seek to improve existing drugs.

Natural Products Most often, drugs originate as substances from natural products, such as plants, animals, minerals, bacteria, or fungi. For hundreds of years, drugs have been made from seeds, bulbs, roots, stems, buds, leaves, and other parts of plants. Two examples of plant-derived drugs are digitoxin, which comes from the foxglove plant (see Figure 51-2), and quinine, which comes from cinchona tree bark. Digitoxin is used to treat heart failure and abnormal heartbeats. Quinine is used to treat malaria.

Animals also are used as a source of drugs. Certain animal substances have been shown to be compatible with human physiology. Some examples of animal substances used as drugs are glandular substances, such as thyroid hormones; fats and oils, such as cod-liver oil; enzymes, such as pancreatin and pepsin; and antiserums and antitoxins for vaccines.

Mineral sources yield various substances that can be used as they occur naturally or mixed with other substances. Two drugs derived from mineral sources are potassium chloride and mineral oil. Simple organisms, such as bacteria and fungi, produce substances that are used to make certain antibiotics, such as cephalosporins and penicillins (see Figure 51-3).

Chemical Development A chemist conducts investigations that lead to the synthesis (creation) of drugs based on a natural substance's chemical properties. Some drugs are synthesized by strictly chemical methods. Others are created by manipulating genetic information in a host organism. For example, human insulin is produced by these means, also known as *recombinant deoxyribonucleic acid (DNA)* techniques.

FIGURE 51-2 The foxglove plant, shown here, is the natural source for the medication digitoxin.

Pharmacodynamics

Pharmacodynamics is the study of the mechanism of action, or how the drug works to produce a therapeutic effect. Drugs are placed in categories based on their mechanism of action. Pharmacodynamics includes the interaction between the drug and target cells or tissues and the body's response to that interaction. For example, when a patient with diabetes takes insulin, the drug acts by allowing the movement of glucose across cell membranes. This movement makes the glucose available to cells to use as an energy source. The end result is a decrease in the blood glucose level.

Go to CONNECT to see an animation exercise about Pharmacokinetics vs. Pharmacodynamics.

Pharmacokinetics

Pharmacokinetics is what the body does to a drug—that is, how the body absorbs, distributes, metabolizes, and excretes the drug. It is important to understand these processes so that you will be able to explain to patients the reasons for taking a particular drug with food or for drinking plenty of water while taking a drug. These four processes can be remembered by using the acronym ADME: Absorption–Distribution–Metabolism–Excretion.

Absorption Absorption is the process of converting a drug from its dose form, such as a tablet or capsule, into a form the body can use. For example, tablets and capsules are absorbed through the stomach or intestines into the bloodstream. Water or a particular food may either hinder or assist the absorption of a specific drug through the stomach or intestines. Some drugs may irritate the digestive organs if they are taken without food or water. Because of such possible reactions, patients must precisely follow instructions for taking a drug with plenty of water, with food, or without food.

Injected drugs are absorbed through the skin (intradermally), through the tissue just beneath the skin (subcutaneously), or through muscle (intramuscularly), depending on the method of injection. Absorption allows the drug to enter the bloodstream and pass into tissues. The extent and rate of drug absorption depend on several factors, including the route of administration. When the drug is administered by mouth, for example, coatings on tablets or capsules and the amount and type of food consumed with the drug may affect absorption. Drugs administered intravenously do not require absorption; they are directly available to target cells from the bloodstream.

Distribution Distribution is the process of transporting a drug from its administration site, such as the muscle of an injection site, to its site of action. Distribution also pertains to the length of time a drug takes to achieve maximum or peak plasma levels—that is, the length of time between dosing and availability in the bloodstream.

Metabolism Drug metabolism is the process by which drug molecules are transformed into simpler products called *metabolites*. This transformation usually occurs in the liver, where enzymes break down the drug. Some drugs, however, are metabolized in the kidneys. Metabolism can be affected by disease, a patient's age or genetic makeup, a drug's characteristics, and other factors. When drugs metabolized in the liver are prescribed for either children or the elderly, the dose is likely to be lower than that prescribed for young adults. Metabolism in children and the elderly is different from metabolism in other patients; the drugs may remain in the body longer and possibly reach harmful levels. The same concern holds true for any patient with impaired liver or kidney function if prescribed drugs are metabolized in the affected organ.

Excretion *Excretion* describes the manner in which a drug is eliminated from the body. Most drugs are eliminated in urine. Drugs also may be excreted in feces, perspiration, saliva, bile, exhaled air, and breast milk.

Go to CONNECT to see animation exercises about Medication Absorption, Medication Distribution, Medication Metabolism, and Medication Excretion.

Pharmacotherapeutics

Pharmacotherapeutics is the study of how drugs are used to treat disease. This area of pharmacology is sometimes called *clinical pharmacology*. Pharmacotherapeutics includes topics such as drug categories, drug indications and labeling, safety, **efficacy** (therapeutic value), and kinds of therapy.

Indications and Labeling An **indication** is the purpose or reason for using a drug. The Food and Drug Administration (FDA) must approve indications before they can become part of a drug's **labeling**. The FDA is an agency of the Department of Health and Human Services. It regulates the manufacture and distribution of every drug used in the United States. Labeling also includes the form of the drug, such as tablet or liquid. Regardless of category, some drugs may be used to treat several different conditions. Multiple uses are possible if the drug affects several body systems at once or if the drug's primary effect produces significant secondary effects in other body systems.

When a drug is used for multiple indications, one or more indications might not be in its labeling. Off-label prescribing is legal. For example, Benadryl® (diphenhydramine) is an antihistamine used to treat allergic symptoms in both children and adults. Because it tends to make a patient sleepy but is safe for children, a pediatrician may use a low dose of Benadryl® as a temporary sedative for a young child. Its use as a sedative, however, is not part of the labeling for Benadryl®.

Another example of a drug with multiple uses is minoxidil. As a trade-name tablet, it is known as the antihypertensive Loniten; as a trade-name topical solution, it is known as the hair-growth stimulant Rogaine®. In the case of minoxidil, both indications are approved, but the tablet labeling is for hypertension and the topical solution labeling is for hair growth. It is important to be aware of these labeling considerations when dealing with questions from patients. Never assume a drug is appropriate for only one use or administered in only one form. Always consult the licensed practitioner or other approved source of drug information before answering a patient's question.

Safety The safety of a drug is determined by how many and what kinds of adverse reactions are associated with it. Adverse reactions include both side effects and adverse effects. **Side effects** are unintended but fairly mild and common effects of a medication. For example, patients may experience constipation as a side effect of taking codeine for pain. Side effects generally are not severe enough to warrant stopping a medication. Some side effects are common, whereas others are rare. **Adverse effects** are potentially more harmful, but less common, effects. For example, reported adverse effects of Benadryl® include confusion and disturbed coordination. A patient experiencing these effects may be told to stop taking Benadryl® because the adverse effects outweigh the benefit of taking the medication. An adverse effect may require immediate attention.

It is not uncommon for a patient to call the physician's office with complaints of new symptoms soon after beginning therapy with a drug. Be alert for such complaints because they might be signs of an adverse reaction to the drug or an interaction with another medication. These calls should be brought to the attention of the licensed practitioner.

Efficacy A patient may complain that a newly prescribed drug is not doing what the doctor said it would. There are a variety of possible explanations for such a complaint, including

- The drug is working adequately, but the patient does not understand how it works.
- The dosage (size, frequency, and number of doses) needs to be adjusted.
- The patient is not taking the medication according to the directions.
- The drug has not yet reached a therapeutic level in the bloodstream.
- The wrong drug was prescribed, or the wrong drug was dispensed by the pharmacy (this is rare, but possible).
- Some drugs work better in some patients than in others; not every drug is for everyone (this is particularly true of antihistamines).
- Some forms of a drug work better than others, such as tablets versus injection.
- The generic drug does not work, but the trade-name drug does. A generic drug may not work because it is made with additional or different inert (not active) ingredients. These inert ingredients could interfere with the drug's active ingredient or could change the patient's response to the medication.

Kinds of Therapy Depending on a patient's condition, the licensed practitioner may use drugs for any of the following kinds of therapy:

- **Acute:** drug is prescribed to improve a life-threatening or serious condition, such as epinephrine for severe allergic reaction
- **Empiric:** drug is prescribed according to experience or observation until blood or other tests prove another therapy to be appropriate, such as penicillin for suspected strep throat
- **Maintenance:** drug is prescribed to maintain health or protect against exacerbations of a condition, especially in chronic disease, such as an anti-inflammatory medication for inflammatory bowel disease
- **Palliative:** drug is prescribed to reduce the severity of symptoms of a condition such as its accompanying pain. For example, morphine is given to reduce the pain caused by cancer
- **Prophylactic:** drug is prescribed to prevent a disease or condition, such as immunizations or birth control drugs
- **Replacement:** drug is prescribed to provide chemicals otherwise missing in a patient, such as hormone replacement therapy for a woman in menopause
- **Supportive:** drug is prescribed for a condition other than the primary disease until that disease resolves, such as a corticosteroid for severe allergic reactions
- **Supplemental:** drug or nutrients are prescribed to avoid deficiency, such as iron for a woman who is pregnant

Toxicology

Toxicology is the study of the poisonous effects, or toxicity, of drugs, including adverse effects and drug interactions. In addition to immediate toxic effects that can occur when drugs are administered, you must be aware of some possible toxic effects that may not be apparent right away:

- An adverse effect on a fetus when the drug crosses the placenta
- An adverse effect on infants when the drug passes easily into breast milk
- Adverse reactions reported in clinical trials, such as headache, drowsiness, gastric upset, or other effects
- An adverse effect in immunocompromised patients who are unable to metabolize a drug normally
- An adverse effect in pediatric or elderly patients or in patients with hypertension, diabetes mellitus, or other serious chronic conditions
- An adverse drug interaction when the drug is taken with another drug or food that is incompatible
- A carcinogenic (cancer-causing) effect in some patients

Adverse reactions are nearly always encountered during the clinical trials of a drug, and there will be mention of these reactions under that heading in the package insert or in accepted drug reference works. In the reports of clinical trials, the drug company must report all adverse reactions noted during testing. As a result, all of the adverse reactions that, at least theoretically, could be caused by the drug are included.

In dealing with patients who are about to begin drug therapy, use discretion when mentioning specific adverse reactions associated with drugs. The patient must be informed; however, you do not want to cause undue alarm or discourage patients from taking the needed medication. Always ask patients if they have any questions and have the licensed practitioner answer patients' drug-related questions. Because patients will receive lists of possible adverse reactions from the pharmacist, encourage them to discuss concerns with the pharmacist or to call the practitioner's office. Also encourage patients to inform the practitioner of adverse reactions they experience after beginning drug therapy.

▶ Drug Names and Categories LO 51.3

One drug may have several different names, including the drug's **generic name** (official, nonproprietary name), chemical name, and **trade name** (brand, or proprietary name). For instance, the trade-name cholesterol-lowering drug prescribed by authorized prescribers as Mevacor® or Altoprev® is also identified by the following names:

- Lovastatin (generic name)
- 2-methyl-1S,2,3R,7S,8S,8aR-hexahydro-3,7-dimethyl-8-[2-[2(2R,4R)-tetrahydro-4-hydroxy-6-oxo-2H-pyran-2-yl]ethyl-1-naphthalenyl ester, butanoic acid (chemical name)

As a medical assistant, you will probably need to use only generic and trade names. In general, think of the generic name of a drug as a simple form of its chemical name. For each new drug

marketed by a manufacturer, the United States Adopted Names (USAN) Council selects a generic name. This name is nonproprietary, meaning it does not belong to any one manufacturer. A generic name is also considered a drug's official name, which is listed in the *United States Pharmacopeia/National Formulary*.

A drug's manufacturer selects the drug's trade name, which is protected by copyright and is the property of the manufacturer. When a new drug enters the market, its manufacturer has a patent on that drug, which means that no other manufacturer can make or sell the drug for 17 years. When the patent runs out, any manufacturer can sell the drug under the generic name or a different trade name. The original manufacturer, however, is the only one allowed to use the drug's original trade name. For example, the antibiotic amoxicillin has two trade names, Amoxil® and Prevpac®. A different manufacturer owns each of these names.

A licensed practitioner may prescribe a drug by its generic or trade name. Because generic drugs are usually less expensive, most practitioners try to prescribe them if possible. Many states allow pharmacists to substitute a generic drug for a trade-name drug unless the practitioner specifies otherwise. In fact, most health insurance prescription plans require the substitution of generic drugs for trade-name drugs (unless otherwise specified by a licensed practitioner). Frequently, they also require the pharmacy to charge a higher copay amount for trade-name drugs than for generic drugs. Some prescription plans offer a mail-in pharmacy, through which a patient can obtain generic drugs with a reduced copayment or without any copayment.

Drugs are categorized by their action on the body, general therapeutic effect, or body system affected. Table 51-1 lists a variety of drug categories, their actions, and common drugs, including drugs from the top 200 drugs most commonly prescribed in the year 2014.

▶ FDA Regulation and Drugs LO 51.4

The Food and Drug Administration (FDA) requires that drug manufacturers perform clinical tests on new drugs before humans use the drugs. These tests include toxicity tests in laboratory animals, followed by clinical studies (clinical trials) in controlled groups of volunteers. Some volunteers are patients; others are healthy subjects. Clinical tests are designed to consider the ratio of benefits to the risk of adverse reactions. If the clinical tests prove the drug is safe and effective, the FDA approves it for marketing. The manufacturer must continue to demonstrate the drug's safety and efficacy and must submit reports whenever it discovers unexpected adverse reactions. The FDA can withdraw a drug from the market at any time if evidence suggests it is no longer safe or effective. This is known as a *recall*.

The FDA also regulates drug manufacturing. It ensures that drugs shipped between states have the proper identity, strength, purity, and quality. Each manufacturer must consistently identify each drug by a particular color, form, shape, size, and label. It must produce every dose at the same tested strength, using the exact formula approved by the FDA. The manufacturer also must use high-quality, contaminant-free ingredients. The FDA regulates all drugs, including over-the-counter, prescription, and even complementary and alternative medicine (CAM). See *Points on Practice: The FDA and CAM Therapies*. To

TABLE 51-1 Drug Categories and Actions for Commonly Prescribed Drugs

Drug Category	Action of Drug	Examples* Generic Name (Trade Name)
Analgesic	Relieves mild to severe pain	Acetaminophen (Tylenol®); acetylsalicylic acid, or aspirin; morphine sulfate (MS Contin®)*; oxycodone HCl (Oxycontin®)*
Anesthetic	Prevents sensation of pain (generally, locally, or topically)	Lidocaine HCl (Xylocaine®; Lidoderm®)*; tetracaine HCl (Pontocaine®)
Antacid/antiulcer	Neutralizes stomach acid	Calcium carbonate (Tums®); esomeprazole (Nexium®)*; lansoprazole (Prevacid®); pantoprazole sodium (Protonix®)*
Anthelmintic	Kills, paralyzes, or inhibits the growth of parasitic worms	Mebendazole (Vermox®); pyrantel pamoate (Combantrin®, Antiminth®)
Antidysrhythmic (antiarrhythmic)	Normalizes heartbeat in cases of certain cardiac arrhythmias	Disopyramide phosphate (Norpace®); propafenone HCl (Rythmol®); propranolol HCl (Inderal®)
Antiasthmatic	Treats or prevents asthma attacks	Montelukast (Singulair®)*; fluticasone propionate/salmeterol (Advair Diskus®)*; albuterol (ProAir HFA®)*
Antibiotics (antibacterial)	Kills bacterial microorganisms or inhibits their growth	Amoxicillin (Amoxil®)*; azithromycin (Zithromax®)*; cefprozil (Cefzil®); ciprofloxacin (Cipro®)*; clarithromycin (Biaxin® XL); clindamycin (Cleocin®)*
Anticholinergic	Blocks parasympathetic nerve impulses	Atropine sulfate (Isopto® Atropine); dicyclomine HCl (Bentyl®); ipratropium (Atrovent®)
Anticoagulant	Prevents blood from clotting	Enoxaparin sodium (Lovenox®); heparin sodium (Hep-Lock®); warfarin sodium (Coumadin®)*
Anticonvulsant	Relieves or controls seizures (convulsions)	Clonazepam (Klonopin®)*; divalproex (Depakote®); phenobarbital sodium (Luminol® Sodium); phenytoin (Dilantin®)
Antidepressant (four types)	Relieves depression	
Tricyclic		Amitriptyline HCl (Elavil); doxepin HCl (Sinequan®)
Monoamine oxidase inhibitor (MAOI)		Phenelzine sulfate (Nardil®); tranylcypromine sulfate (Parnate®)
Selective serotonin reuptake inhibitor (SSRI)		Escitalopram (Lexapro®)*; fluoxetine HCl (Prozac®); paroxetine (Paxil®)*; sertraline HCl (Zoloft®)*
Serotonin-norepinephrine reuptake inhibitor (SNRI)		Venlafaxine HCl (Effexor XR®)*; duloxetine HCl (Cymbalta®)*
Antidiabetic	Treats diabetes by reducing glucose	Metformin (Glucophage®)*; glipizide (Glucotrol®) pioglitazone HCl (Actos®)*; insulin glargine (Lantus®)*
Antidiarrheal	Relieves diarrhea	Bismuth subsalicylate (Pepto-Bismol®); kaolin and pectin mixtures (Kaopectate®); loperamide HCl (Imodium®)
Antiemetic	Prevents or relieves nausea and vomiting	Prochlorperazine (Compazine®); promethazine (Phenergan®); trimethobenzamide HCl (Tigan®)
Antifungal	Kills or inhibits growth of fungi	Amphotericin B (Fungizone®); fluconazole (Diflucan®)*; nystatin (Mycostatin®); terbinafine (Lamisil®)
Antihistamine	Counteracts effects of histamine and relieves allergic symptoms	Cetirizine HCl (Zyrtec®); diphenhydramine HCl (Benadryl®); fexofenadine (Allegra®); desloratadine (Clarinex®)
Antihypertensive	Reduces blood pressure	Amlodipine (Norvasc®)*; diltiazem HCl (Cartia XL®); quinapril (Prinivil®); metoprolol succinate (Toprol-XL®)*; valsartan (Diovan®)*
Anti-inflammatory (two types)	Reduces inflammation	
Nonsteroidal (NSAIDs)		Naproxen (Aleve®)*; colchicine* (Colcrys®); ibuprofen (Motrin®, Advil®)*; celecoxib (Celebrex®)*
Steroids		Dexamethasone (Decadron®); methylprednisolone (Medrol®)*; prednisone (Deltasone™)*; triamcinolone (Kenalog®)*

(Continued)

TABLE 51-1 Drug Categories and Actions for Commonly Prescribed Drugs

Drug Category	Action of Drug	Examples* Generic Name (Trade Name)
Antilipemic (antilipidemic)	Lowers blood lipids such as triglycerides	Gemfibrozil (Lopid®); atorvastatin (Lipitor®)*; fenofibrate (TriCor®)*; ezetimibe/simvastatin (Vytorin®)*; ezetimibe (Zetia®)*; rosuvastatin (Crestor®)*
Antineoplastic	Prevents or inhibits the growth of cancer	Bleomycin sulfate (Blenoxane®); dactinomycin (Cosmegen®); paclitaxel (Taxol®); tamoxifen citrate (Nolvadex®)
Antipsychotic	Controls psychotic symptoms	Chlorpromazine HCl (Thorazine®); clozapine (Clozaril®); haloperidol (Haldol®); risperidone (Risperdal®)*; thioridazine HCl (Mellaril®)
Antipyretic	Reduces fever	Acetaminophen (Tylenol®); acetylsalicylic acid, or aspirin
Antiseptic	Inhibits growth of microorganisms	Isopropyl alcohol; 70% povidone-iodine (Betadine®); chlorhexidine gluconate (PerioChip®)
Antitussive	Inhibits cough reflex	Codeine; dextromethorphan hydrobromide (component of Robitussin® DM)
Bronchodilator	Dilates bronchi (airways in the lungs)	Albuterol (Proventil®)*; epinephrine (Epinephrine Mist); salmeterol (Serevent®); tiotropium bromide (Spiriva®)*
Cathartic (laxative)	Induces defecation, alleviates constipation	Bisacodyl (Dulcolax®); casanthranol (Peri-Colace®); magnesium hydroxide (Milk of Magnesia®)
Contraceptive	Reduces risk of pregnancy	Ethinyl estradiol and norgestimate (Ortho Tri-Cyclen®); norethindrone and ethinyl estradiol (Loestrin® 24 Fe)* norgestrel (Ovrette®)
Decongestant	Relieves nasal swelling and congestion	Oxymetazoline HCl (Afrin®); phenylephrine HCl (Neo-Synephrine®); pseudoephedrine HCl (Sudafed®)
Diuretic	Increases urine output, reduces blood pressure and cardiac output	Bumetanide (Bumex®); furosemide (Lasix®)*; hydrochlorothiazide (HydroDIURIL®)*; mannitol (Osmitol®); spironolactone (Aldactone®)
Expectorant	Liquefies mucus in bronchi; allows expectoration of sputum, mucus, and phlegm	Guaifenesin (Mucinex®)
Hemostatic	Controls or stops bleeding by promoting coagulation	Aminocaproic acid (Amicar®); phytonadione or vitamin K ₁ (Mephyton®); thrombin (Thrombogen)
Hormone replacement	Replaces or resolves hormone deficiency	Insulin (Humulin®) for pancreatic deficiency; levothyroxine sodium (Synthroid®)* for thyroid deficiency; conjugated estrogens (Premarin Tabs®)*
Hypnotic (sleep-inducing) or sedative	Induces sleep or relaxation (depending on drug potency and dosage)	Chloral hydrate (Noctec®); secobarbital sodium (Seconal® Sodium); zolpidem (Ambien®)*
Muscle relaxant	Relaxes skeletal muscles	Carisoprodol (Rela or Soma®); cyclobenzaprine HCl (Flexeril®)*
Mydriatic	Constricts vessels of eye or nasal passage, raises blood pressure, dilates pupil of eye in ophthalmic preparations	Atropine sulfate (Atropisol) for ophthalmic use; phenylephrine HCl (Alcon Efrin) for ophthalmic use or (Neo-Synephrine®) for nasal use
Stimulant (central nervous system)	Increases activity of brain and other organs, decreases appetite	Amphetamine sulfate (Benzedrine); caffeine (No-Doz®); also a component of many analgesic formulations and coffee
Vasoconstrictor	Constricts blood vessels, increases blood pressure	Dopamine HCl (Intropin); norepinephrine bitartrate (Levophed®)
Vasodilator	Dilates blood vessels, decreases blood pressure	Enalapril (Vasotec®); lisinopril (Prinivil®)*; nitroglycerin (Nitrostat®, NitroQuick®)

*Indicates top 200 commonly prescribed drugs in the year 2014.

Sources: RxList, <http://www.rxlist.com>.

help regulate the safety of drugs, the FDA has a program called MedWatch for voluntary reporting of adverse events noted during clinical care. An adverse event is any undesirable experience for a patient associated with the use of a medical product. Reporting of these events is done on the FDA site at <http://www.fda.gov/Safety/MedWatch/default.htm>.

Over-the-Counter Drugs

A nonprescription, or over-the-counter (OTC), drug is one the FDA has approved for use without a licensed healthcare practitioner's supervision. The consumer must follow the manufacturer's directions to use the drug safely. Some drugs, such as aspirin and vitamin supplements, have been OTC drugs for many years. The number of prescription drugs granted OTC status is increasing. Although OTC drugs are safe when used as directed on the package, patient education contributes significantly to their safe use.

Prescription Drugs

A prescription drug is one that can be used only by order of a licensed practitioner. It must be dispensed by a licensed healthcare professional, such as a pharmacist, physician, podiatrist, or licensed midwife. Some prescription drugs are available at much lower strengths as OTC medications.

Pregnancy Categories

Because clinical trials are not typically done on pregnant women, most of the data about the effect of medications on pregnant women are obtained after FDA approval. Drugs can cause defects to the fetus if taken during pregnancy. Prior to June 2015, drugs were labeled as a category A, B, C, D, or X based on the degree to which information has ruled out risk to the fetus. In June 2015, more comprehensive labeling requirements were set for three categories: Pregnancy, Lactation, and Females and Males of Reproductive Potential. The new

POINTS ON PRACTICE

The FDA and CAM Therapies

Complementary and alternative medicine (CAM) such as dietary supplements, herbal products, and other natural but as yet scientifically unproven therapies are increasing in use. Many licensed practitioners prescribe these therapies and even more patients take them on their own with positive effects.

There is one important difference between dietary supplements and medications. Medications must earn FDA approval prior to being marketed and sold. Drug manufacturers must provide scientific documentation of the effectiveness of a drug before it can be marketed. On the other hand, manufacturers of dietary supplements do not have to provide evidence of effectiveness or safety. Of course, they are not permitted to market or sell a product that is proven unsafe. However, once a supplement is marketed, the FDA must prove that the product is not safe to have it taken from the market. Additionally, dietary supplements are not standardized between batches or among manufacturers. Standardization is a process that ensures the consistency and quality of each batch of supplement produced. Thus, the amount and quality of a dietary supplement may differ between batches produced by one manufacturer or between the same supplement made by two different manufacturers. FDA-approved medications must be standardized and will always be consistent between batches and manufacturers.

The FDA does require that certain information appear on dietary supplement labels. Dietary supplements may include claims on their labels that describe the effect of a substance in maintaining the body's normal structure or function. For example, a label might state "Promotes healthy joints and bones." The FDA does not review or authorize this claim, so the manufacturer is also required to place a disclaimer on the product. This disclaimer is a statement indicating that the claims have not been evaluated by the FDA—for example, "This statement has not been evaluated by the Food and Drug

Administration. This product is not intended to diagnose, treat, cure, or prevent disease." Figure 51-4 shows an example of a label that meets the FDA's labeling requirements.

FIGURE 51-4 The Food and Drug Administration provides specific guidelines for the information to be included on a dietary supplement label.

TABLE 51-2 Pregnancy and Lactation Drug Label Requirements (June 2015)

The FDA requires the following information on prescription drug labels to assist the prescriber and the patient in determining the risks and benefits of each.

Category	Label Requirements
Pregnancy (Includes Labor and Delivery)	• Pregnancy/fetal risk summary • Clinical considerations and data • Inadvertent exposure considerations • Prescribing decisions for pregnant patients • Information for the pregnancy exposure registry when available
Lactation (Includes Nursing Mothers)	• Information about the amount of drug in the breast milk • Information about potential effects of the drug on the breastfed infant
Females and Males of Reproductive Potential	• Need for pregnancy testing when taking the drug • Contraception recommendations • Information about infertility as it relates to the drug

labeling requirement starts for all medications submitted to the FDA after June 30, 2015, and the old labeling will be phased out. The new labels include pregnancy exposure registries that collect and maintain data on the effects of medications used by pregnant women. The new rule dictates what must be included on the drug label based on the three categories. See Table 51-2.

► Sources of Drug Information LO 51.5

Having access to up-to-date and credible sources of drug information in the office is essential. The most up-to-date resources are found online or through smartphone or other electronic applications. Books are available, but resource books are also

available online. *Physicians' Desk Reference*® (Figure 51-5), *United States Pharmacopeia/National Formulary*, *American Hospital Formulary Service (AHFS)*®, and *Epocrates*® are credible sources of drug information. Package inserts and drug labels are also valuable drug information sources.

Physicians' Desk Reference® (PDR)

The *Physicians' Desk Reference*®, or *PDR*, is published annually, along with supplements twice a year. It is sent free to doctors' offices and sold through bookstores. PDR Network, the company that publishes the *PDR*, also publishes separate editions for generic, nonprescription, and ophthalmologic drugs, as well as a guide to drug interactions, adverse effects, and

The screenshot displays the PDR.net website interface. At the top, there is a navigation bar with links: HOME, DRUG INFORMATION, DRUG COMMUNICATIONS, PHARMACY SAVINGS, RESOURCES, and CLINICAL ARTICLES. A login section for PDR MEMBER LOGIN is visible, with fields for Email or Username, Password, and a Remember me checkbox. Below the navigation bar, there is a large advertisement for the PDR mobile app, featuring a smartphone and the text 'It's here... The official comprehensive drug reference and comparison app from PDR. INSTALL NOW - FREE -'. A search bar labeled 'PDR Search' with the placeholder 'type drug name here...' and a 'GO' button is present. Below the search bar, there is another advertisement for the 'PDR® Pharmacy Discount Card Mobile' app, with a 'Download Today!' button. At the bottom, there are four small boxes with links to 'mobilePDR®', 'PDR Drug Communications', 'Savings on Consumer Health products', and 'PDR Pharmacy Discount Card'. The footer contains links for 'About Us', 'Help', 'Contact Us', 'Order Books', 'Report Adverse Events', 'Privacy Policy', and 'Terms of Service', along with a disclaimer and copyright information.

FIGURE 51-5 PDR.net® is a complete and current resource for drug information which includes all the information found in the PDR.

Physicians' Desk Reference. 70th ed. Montvale, NJ: PDR, LLC; 2015:100–105

indications. It is also available online. The *PDR* presents information provided by pharmaceutical companies about more than 2,500 prescription drugs. It has the following sections:

- Section 1—manufacturer's index (color-coded white), which includes the pharmaceutical company's name, address, emergency telephone number, and available products
- Section 2—brand- and generic-name index (color-coded pink)
- Section 3—product category index (color-coded blue)
- Section 4—product identification guide with full-color photos of more than 2,400 medications
- Section 5—product information
- Section 6—diagnostic product information

The product information section is divided according to manufacturer, and the drugs are then grouped alphabetically within each manufacturer's subsection. The information is provided for the *PDR* by the manufacturer and is either the drug package insert or a similar document.

After the large product information section, various smaller other sections are provided, which include diagnostic product information, state drug information centers, ratings for drug use in pregnancy, a state DEA directory, state-aided drug-assistance programs, patient assistance programs, drugs that should not be crushed, dosing instructions in Spanish, and the system for reporting adverse reactions to medications. All of these plus the *PDR* Internet site and *PDR* electronic library that come with the *PDR* are important resources for drug information.

United States Pharmacopeia/ National Formulary

The *United States Pharmacopeia/National Formulary*, or *USP-NF*, is the official source of drug standards in the United States, published about every 5 years. It is the official public standards-setting authority for all prescription medications, OTC drugs, dietary supplements, and other healthcare products. By law, every product sold under a name listed in the *USP-NF* must meet the USP's strict standards.

The *USP-NF* describes each product approved by the federal government and lists its standards for purity, composition, and strength as well as its uses, dosages, and storage. The NF portion of the book provides the chemical formulas of the drugs. The *USP-NF* is available online.

American Hospital Formulary Service (AHFS®)

The American Society of Hospital Pharmacists in Bethesda, Maryland, publishes *American Hospital Formulary Service Drug Information*®, or *AHFS DI*. It sells the two-volume set by subscription and provides four to six supplements each year. The *AHFS*® lists generic names and is divided into sections based on drug actions. The *AHFS*® is also available online.

Epocrates®

Epocrates® is a software program that can be loaded onto a smartphone or other personal digital assistant. Epocrates® includes more than 3,300 brand and generic drugs, alternative

medicines, a drug-drug interaction checker, an IV compatibility checker, health insurance Medicare Part D formularies, and an infectious disease treatment guide.

Package Insert

The **package insert** for each drug describes the drug: its purpose and effects (clinical pharmacology), indications, contraindications (conditions under which the drug should not be administered), warnings, precautions, adverse reactions, drug abuse and dependence, overdosage, and dosage and administration, as well as how the drug is supplied (for example, tablets in different doses, or liquid). The package insert, whether part of the *PDR* or found in the medication package, is a valuable resource for drug information. See Figure 51-6.

Drug Labels

To prepare and administer drugs, you must understand information that appears on drug labels, including the drug name, form, dosage strength, total amount in the container, route of administration, warnings, storage requirements, and manufacturing information. See Figure 51-7. By law, the generic name, as listed in the *USP-NF*, must appear on the drug's label. The drug label also may include the trade (brand) name used to market the drug. The trade name is typically indicated by the registered trademark symbol®. The form of the drug is included, such as tablet, capsule, or liquid for oral administration. In some cases, a drug may be a combination drug, meaning more than one drug is in each tablet, capsule, or amount of liquid. Drug labels also include information about the amount of the drug present.

On the label, the dosage strength is stated as the amount of drug per dosage unit. In most cases, the amount of the drug is listed in grams (g), milligrams (mg), or micrograms (mcg), or if it is a liquid, in milliliters (mL). If a container holds more than one dose of medication, then the total number or volume of medication is listed on the label.

The label also should include the route of administration, especially if it is a liquid. Warnings, such as "May be habit forming," are included, as well as storage information. Storage information indicates the specific conditions under which a medication must be stored. The manufacturer's information is always included. Information about how to mix or reconstitute a medication also may be found on the label.

▶ Controlled Substances

LO 51.6

A **controlled substance** is a drug or drug product categorized as potentially dangerous and addictive. The greater the potential for abuse, the more severe the limitations on prescribing it. Federal laws strictly regulate use of these controlled drugs. States, municipalities, and institutions must adhere to these laws but may also impose their own regulations, as long as they are at least as strict as the federal laws.

Comprehensive Drug Abuse Prevention and Control Act

The Comprehensive Drug Abuse Prevention and Control Act, also known as the Controlled Substances Act (CSA) of 1970,

FIGURE 51-6 Use the package insert to become familiar with a drug's indications, contraindications, dosage, and potential adverse reactions.

is the federal law that created the DEA and strengthened drug enforcement authority. The CSA designates five schedules, according to degree of potential for a substance to be abused or used for a nontherapeutic effect. Schedule I drugs do not have a medical use and cannot be prescribed in the United States. Schedule II drugs include **opioids**, which are natural or synthetic drugs that produce opium-like effects. Examples of Schedule II drugs include codeine, morphine, and meperidine (Demerol®). Government agencies use the popular term **narcotics** for opioids. Prescription requirements are the strictest for Schedule II drugs. Schedule III through V drugs have reduced prescription requirements and are progressively less addictive the larger the schedule number.

Sometimes the DEA reclassifies drugs. For example, a Schedule III drug may eventually be found to be less addictive than originally determined and therefore reclassified as a Schedule IV drug. The five schedules, their prescription and legal requirements, and examples of substances in each are outlined in Table 51-3.

Controlled Substance Labeling

The CSA also set up a labeling system to identify controlled substances. An example of this label is shown in Figure 51-8. The large C means the drug is a controlled substance and the Roman numeral inside the C corresponds to the drug's DEA schedule.

FIGURE 51-7 (a) Check the medication label carefully. (b) Always read reconstitution instructions and storage information. (c) Note any warnings on the label.

FIGURE 51-8 This symbol indicates that the drug is a Schedule II controlled substance.

Doctor Registration and Drug Ordering

Authorized prescribers who administer, dispense, or prescribe any controlled substance must register with the DEA and have a current state license to practice medicine and, if required, a state-controlled substance license. They also must comply with all aspects of the CSA. This includes registration, renewal, and ordering of controlled substances. For example, DEA Form 224 is used to register a practitioner, DEA Form 222 is used to order scheduled drugs, and DEA Form 41 is

used to dispose of these drugs. Procedure 51-1 at the end of this chapter outlines this process.

Drug Security

Drugs that are controlled substances must be kept in a locked cabinet or safe. If required by state law, use double locks for opioids. The licensed practitioner should keep the key(s) at all times, except when asking you to add to or take from the stock (if this is a task medical assistants are permitted to perform in your state). If controlled drugs are stolen from the licensed practitioner's office, call the regional DEA office at once. Also, notify the state bureau of narcotic enforcement and the local police. File all reports required by the DEA and other agencies as a follow-up.

Recordkeeping

A licensed practitioner who administers and/or dispenses controlled drugs to patients from his facility must maintain two types of records: dispensing records and inventory records. However, if the physician only writes (but does not dispense or administer) prescriptions for controlled drugs, these two types of records are not necessary.

Dispensing Records The dispensing record for Schedule II drugs must be kept separate from a patient's regular medical record. Each time a drug is administered or dispensed, the

TABLE 51-3 Schedule of Controlled Substances

Schedule	Description	Prescription and Legal Considerations	Examples
I	High abuse potential (no accepted medical use)	No prescriptions written	GHB, heroin, LSD, mescaline
II	High abuse potential (accepted medical use; abuse may lead to dependence)	- Must be written by DEA-licensed physician and include DEA number - Multiple and/or special forms may be required - Must be filled in 7 days and cannot be refilled - Must be stored under lock and key - Dispensing records kept for 2 years	Opioids: morphine (MS-Contin®), meperidine (Demerol®), fentanyl (Duragesic®) Barbiturates: secobarbital Amphetamines: Methylphenidate (Ritalin®)
III	Lower abuse potential than Schedule I and II drugs (accepted medical use; abuse may lead to moderate dependence)	- Five refills allowed in 6 months - Handwritten by physician - Can be telephoned by physician only	Anabolic steroids Analgesic: hydrocodone/codeine (Vicodin®), Tylenol 3® Barbiturate: talbutal Antidiarrheal: Paregoric
IV	Lower abuse potential than Schedule III drugs (accepted medical use; abuse may lead to limited dependence)	- Five refills allowed in 6 months - Must be signed by physician - Refills may be authorized over the phone - Inventory records must be kept on these drugs	Benzodiazepines: alprazolam (Xanax®), chloridiazepoxide (Librium®), diazepam (Valium®), zolpidem (Ambien®), pentazocine (Talwin®)
V	Lower abuse potential than Schedule IV drugs (accepted medical use; very limited physical dependence)	- Inventory records must be kept on these drugs - Five refills allowed in 6 months - Must be signed by physician - Refills may be authorized over the phone	Antitussive and antidiarrheals that combine small amounts of opioids, including Lomotil®, Kaolin, and Robitussin AC®

Source: US Department of Justice, Drug Enforcement Administration, Office of Diversion Control, <http://www.deadiversion.usdoj.gov>.

licensed practitioner must note the date, the patient's name and address, the drug, and the quantity dispensed. The dispensing record for drugs on Schedules III through V must include the same information. The record for these drugs may be kept in the patient's medical record unless the physician charges for the drugs dispensed. All dispensing records must be kept for 2 years and are subject to inspection by the DEA.

Inventory Records A licensed practitioner who regularly dispenses controlled drugs also must keep inventory records of all stock on hand. This regulation applies to all scheduled drugs. To take an inventory, count the amount of each drug on hand. Compare this amount with the amount of the drug ordered and the amount dispensed to patients. The controlled drug inventory must be repeated every 2 years. You must include copies of invoices from drug suppliers in the inventory record. All Schedule II drug inventories and records must be kept separate from other records.

Inventories and records of other controlled drugs must be separate or easily retrievable from ordinary business and professional records. All records on controlled drugs must be retained for 2 years and made available for inspection and copying by DEA officials if requested.

Disposing of Drugs If the doctor asks you to dispose of any outdated, noncontrolled drugs, you will most likely use the disposal company that takes your biohazardous waste. The DEA does not allow businesses to flush any medications, and medications should not be placed in the trash. In some cases, you may work with a larger healthcare facility or pharmacy to ensure proper disposal so that medications do not pollute the environment or end up in the trash, where someone may take them.

If the licensed practitioner needs to dispose of controlled drugs, such as expired samples, obtain DEA Form 41, called Registrants Inventory of Drugs Surrendered, which is available from the nearest DEA office or the Internet. Complete the form in quadruplicate, have the doctor sign it, and call the DEA to obtain instructions for disposal of the drugs. If you must ship them, use registered mail. After the drugs have been destroyed, the DEA will issue the licensed practitioner a receipt, which you should keep in a safe place. If practitioners terminate their medical practice, they must return their DEA registration certificate and any unused copies of DEA Form 222, which is used for ordering scheduled medications, to the nearest DEA office. To prevent unauthorized use, write the word VOID across the front of these forms. Regional DEA offices will tell the practitioner how to dispose of any remaining controlled drugs.

► Prescriptions

LO 51.7

Any drug not available over the counter requires a prescription. As a medical assistant, you should be able to interpret a prescription in order to discuss it with the patient, authorized prescriber, or pharmacist. You must become familiar with the prescriber's style of writing or the electronic prescription process at your facility.

Interpreting a Prescription

Prescriptions for new or refilled medications are completed or approved by the licensed practitioner. A prescription has specific parts that must be present before it can be filled or refilled (Figure 51-9).

The basic components of a prescription are

1. *Prescriber information:* Name, address, telephone number, and other information identifying the prescriber.
2. *Patient information:* Patient's full name, date of birth, address, and other information to identify the patient.
3. *Medication prescribed:* Includes generic or brand name, strength, and quantity. This is sometimes called the inscription and is found after the Rx.
4. *Subscription:* Instructions to the pharmacist dispensing the medication. This may include generic substitution and refill authorization.
5. *Signa:* Also known as the transcription; refers to patient instructions. These instructions generally follow the abbreviation *Sig*, which means "mark."
6. *Signature:* Prescriber's signature for handwritten prescriptions. The prescriber's signature must be in ink, but it cannot be a stamped signature. A digital signature is used if it is secure; otherwise, the prescription must be printed and then signed or otherwise authorized. The prescriber must also include the date the prescription was generated.
7. *DEA number:* This is required for prescriptions of Schedules II, III, IV, and V medications only.

Many terms and abbreviations are used in prescriptions. See Table 51-4 for some examples. Abbreviations for drug names should not be used, because there are similar abbreviations for multiple drugs. Recall from the *Patient Interview and History* chapter that there are many abbreviations that should not be used. These are known as the "Do Not Use" abbreviations, as identified by The Joint Commission (<http://www.jointcommission.org>), and "Error Prone," as identified by the Institute for Safe Medical Practices (<http://www.ismp.org>).

A medical assistant must be able to interpret a prescription with accuracy. Refer to Procedure 51-2 at the end of this chapter.

Managing Prescriptions Prescriptions may be printed or handwritten on a prescription blank. They also may be entered electronically and printed, or entered electronically and transmitted directly to a pharmacy. When the information is entered electronically and transmitted directly, this is known as **e-prescribing**. With e-prescribing, the medication information is received at the pharmacy; the actual prescription is never in the patient's hands. This is the most secure and efficient way for prescriptions to be completed. See *Points on Practice: E-prescribing*.

In rare cases, preprinted prescription blanks are used that include the licensed practitioner's name, address, telephone number, state license number, and DEA registration number plus blank space for writing the patient's name and address, the date, and other information. To prevent unauthorized use

of prescription blanks, never leave them unattended. Most frequently, prescriptions are entered into an EHR, then printed and signed for patients to take with them to the pharmacy. If something about a prescription arouses suspicion, the pharmacist who receives a prescription may call the licensed practitioner's office to verify it. You should be able to check the patient's records and tell the pharmacist whether the practitioner wrote a prescription for that patient. If the prescription

is a forgery, notify the licensed practitioner and, if she gives you authorization, notify the DEA.

Telephone Prescriptions If requested by the licensed practitioner, you may telephone a new or renewal prescription to the patient's pharmacy. You may not, however, telephone a prescription for a Schedule II drug. In an emergency situation, when a patient needs a drug immediately and no alternative

POINTS ON PRACTICE

E-Prescribing

On July 15, 2008, Congress enacted the Medicare Improvements for Patients and Providers Act of 2008 (MIPPA) and it became law. MIPPA provided positive incentives for practitioners who used electronic prescribing in 2009 through 2013. E-prescribing is intended to bring greater safety to patients by providing for automatic drug and allergy interaction checking and by eliminating medication errors due to poor handwriting. E-prescribing also is designed to bring greater efficiency to the prescribing process for providers, as it dramatically decreases communications from pharmacies, requesting prescription clarifications.

Surescripts is the national clearinghouse for e-prescribing. The company electronically connects authorized prescribers,

pharmacists, and payers nationwide, enabling them to exchange health information and prescribe without paper. Surescripts collaborates with national EHR vendors, pharmacies, and health plans to support authorized prescribers using EHR software. With this network in place, healthcare providers can electronically access prescription information from pharmacies, health plans, and other providers to see the patient's total prescription history from all sources. Through e-prescribing, EHRs are providing meaningful improvements in cost, quality, and patient safety. For example, when a medication is taken off the market, a record of all patients who have been prescribed this medication can be queried electronically and the prescribers and patients notified of the change.

TABLE 51-4 Abbreviations Used in Prescriptions

Abbreviation	Meaning	Abbreviation	Meaning
$\bar{a}$	Before	min	Minute, minimum
aa	Of each	mL	Milliliters
ac	Before meals	mm	Millimeters
AM	Morning	neb	Nebulizer
amp	Ampule	noct	Night
apl	Applicatorful	NPO	Nothing by mouth
aq	Water	nr	No refills
bid	Twice daily	oz	Ounce
$\bar{c}$	With	pc	After meals
cap	Capsule	per	By means of; through
cd	Cycle day (menstrual cycle)	PM	Evening or nighttime
cmpd	Compound	po, PO	By mouth
cr	Cream	PR, pr	Rectally
d	Daily or day	q	Every
DAW	Dispense as written (no generic)	qam	Every morning
disp	Dispense	q4h	Every 4 hours
ds	Double strength	qid	Four times daily
dx	Diagnosis	qs	Sufficient amount
elix	Elixir	r, rec	Rectally
eq	Equivalent	rept	Repeat
g, gm	Gram	rf	Refill(s)
gen	Generic	$\bar{s}$	Without
gr	Grain (60 to 65 mg)	stat	Immediately
gtt	Drop(s)	subcut, subQ	Subcutaneously
h, hr	Hour	sup	Suppository
H ₂ O	Water	susp	Suspension
IM	Intramuscularly	sx	Symptoms
inj	Inject, injection	syr	Syrup
IV	Intravenously	tab	Tablet(s)
kg	Kilogram	tblsp	Tablespoon
L	Liter	tsp	Teaspoon
liq	Liquid	tx	Treatment
lot	Lotion	ud, utd	As directed
MDI	Metered dose inhaler	ung	Ointment
mEq	Milliequivalent	vag	Vaginally, into vagina
mg	Milligram(s)	YO	Years old

is available, the physician may telephone a prescription for a Schedule II drug. The amount must be limited to the period of emergency, and a written prescription must be sent to the pharmacist within 72 hours. The pharmacist must notify the DEA if a written prescription does not arrive within the specified time.

Patient requests for prescription renewals occur daily. The renewal requests may be called in to the receptionist or left on a designated phone or mail system. It is the medical assistant's

responsibility, if asked, to handle the prescription renewals/refills in an appropriate manner.

► Nonpharmacologic Pain Management

LO 51.8

Because of drug interactions, adverse reactions, or the risk of dependence, many patients either prefer not to or should not take drugs to relieve chronic pain. The overuse and abuse of pain medications can be a problem. Pain frequently motivates these patients to use complementary and alternative medicine (CAM). The following are some examples:

- Chiropractors use spinal adjustments to treat chronic back or neck pain.
- Massage is used to treat headache or arthritis and to promote healing through relaxation.
- An acupuncture procedure in which very small amounts of electrical current are applied through needles has been used successfully to block the pain of surgery without anesthesia.
- Yoga uses postures to exercise the spine and stimulate the lymphatic system, helping to remove from the body toxins that may cause pain and stiffness in muscles and joints.
- Meditation is said to balance a person's physical, emotional, and mental states and is used as an aid in treating stress, anxiety, and pain.
- Hypnotism may be used to help patients overcome pain caused by stress-induced migraine headaches.
- Glucosamine chondroitin, a dietary supplement, is taken to treat osteoarthritis by reducing pain and slowing down joint cartilage damage.
- **Magnetic therapy** involves the use of magnets of varying sizes and strengths placed on the body to relieve pain or treat disease.
- Biofeedback can help a patient learn to evoke relaxation, which helps block pain perception.

CAM approaches and therapies have become more common in recent years. Some physicians and patients are seeking agents and treatments to manage health problems, such as chronic pain, that are less expensive, have fewer side effects, and are more accessible than traditional medical interventions. Pain clinics that use multiple pain management techniques are common.

► Vaccines

LO 51.9

A vaccine is a preparation made from microorganisms and administered to a person to produce reduced sensitivity to, or increased immunity to, an infectious disease. Vaccines are stored with the office supply of drugs and require similar handling. If you work in a pediatrician's office, you will handle the vaccines for childhood diseases. In an adult practice, you can expect to see influenza and pneumonia vaccines and vaccines for diseases to which patients might be exposed in foreign travel.

It is important to know how vaccines work in the immune system. Through the immune system's action, a patient can be protected from—or made not susceptible to—a disease. This

immunity results from the formation of antibodies that destroy or alter disease-causing agents. You can review information about immunity discussed in the chapter *The Lymphatic and Immune Systems*.

Antibody Formation

Antigens are foreign substances—bacteria, viruses, and other organisms—that can enter the human body in spite of its natural defenses. In response to an invasion by antigens, the body's specialized white blood cells (lymphocytes) produce antibodies. These antibodies are specific to the invading antigens and combine with the antigens to neutralize them. This action arrests or prevents the reaction or disease that the antigens would otherwise cause. Toxins, pollens, and drugs also can be antigens if the body reacts to them by forming antibodies. (Allergens are antigens that induce an allergic reaction.)

Vaccines contain organisms that have been killed or attenuated (weakened) in a laboratory. Because the organisms have been weakened, they stimulate antibody formation but do not overpower the body and cause disease. They may, however, still be strong enough to cause a fever and slight inflammation at the injection site. Some vaccines, such as those for influenza, may even produce some of the lesser effects of the disease against which they provide protection.

Immunizations made from organisms are called *vaccines*. Those made from the toxins of organisms are called *toxoids*. Some immunizations, such as the polio vaccine, last a lifetime. Others, such as tetanus toxoid, do not. In the latter case, booster immunizations must be used to stimulate the lymphocytes to produce antibodies again.

Immunizations

The Advisory Committee on Immunization Practices, the American Academy of Pediatrics, and the American Academy of Family Physicians jointly publish immunization schedules (see the *Assisting in Pediatrics* chapter). These schedules cover children from infancy through 18 years of age. Just as children receive immunizations before exposure to disease, adults may receive immunizations for influenza, pneumonia, or other diseases, including those to which an adult could be exposed during travel. Figure 51-10 displays the adult immunization schedules based on age and on health condition.

Patients are sometimes immunized after exposure. For example, if patients have been exposed to a serious disease and there is too little time for them to produce antibodies, they may receive an antiserum containing antibodies to the disease-carrying organism. These immunizations are made from human or animal serum. If bacterial toxins (rather than bacteria) cause the disease, the patient may receive an antitoxin.

Antisera and antitoxins must be used cautiously and are usually reserved for life-threatening infectious diseases. Because patients can be allergic to substances in animal antisera and antitoxins, human sera are usually preferred. An example of a postexposure immunization is one given to a patient who has been exposed to hepatitis B virus (HBV). This patient should be given the antiserum hepatitis B immune globulin (HBV-Ig) within 7 days after exposure and again

2015 Recommended Immunizations for Adults: By Age

If you are this age, talk to your healthcare professional about these vaccines

	Flu Influenza	Td/Tdap Tetanus, diphtheria, pertussis	Shingles Zoster	Pneumococcal		Meningococcal	MMR Measles, mumps, rubella	HPV Human papillomavirus		Chickenpox Varicella	Hepatitis A	Hepatitis B	Hib Haemophilus influenzae type b
				PCV13	PPSV23			for women	for men				
19–21 years									3 doses				
22–26 years							1 or 2 doses	3 doses	3 doses				
27–49 years		1 dose of Tdap*		1 dose	1 or 2 doses	1 or more doses							
50–59 years	Flu vaccine every year	Td booster every 10 years								2 doses	2 doses	3 doses	1 or 3 doses
60–64 years			1 dose										
65+ year				1 dose	1 dose								

More Information: There are several flu vaccines available. Talk to your healthcare professional about which flu vaccine is right for you.

*If you are pregnant, you should get a Tdap vaccine during the 3rd trimester of every pregnancy to help protect your babies from pertussis (whooping cough).

You should get zoster vaccine even if you've had shingles before.

There are two different types of pneumococcal vaccine: PCV13 (conjugate) and PPSV23 (polysaccharide). Talk with your healthcare professional to find out if one or both pneumococcal vaccines are recommended for you.

Your healthcare professional will let you know how many doses you need.

Recommended for you if you did not get it when you were a child.

If you were born in 1957 or after, and don't have a record of being vaccinated or having had measles, mumps and rubella, talk to your healthcare professional about how many doses you may need.

There are two HPV vaccines but only one HPV vaccine (Gardasil®) should be given to men.

If you are a male 22 through 26 years old and have sex with men you should complete the HPV vaccine series if you have not already done so.

Your healthcare professional will let you know how many doses you need.

(a)

2015 Recommended Immunizations for Adults: By Health Condition

If you have this health condition, talk to your healthcare professional about these vaccines

	Flu Influenza	Td/Tdap Tetanus, diphtheria, pertussis	Shingles Zoster	Pneumococcal		Meningococcal	MMR Measles, mumps, rubella	HPV Human papillomavirus		Chickenpox Varicella	Hepatitis A	Hepatitis B	Hib Haemophilus influenzae type b
				PCV13	PPSV23			for women	for men				
Pregnancy		*see below			1–2 doses								
Weakened Immune System			SHOULD NOT GET VACCINE				SHOULD NOT GET VACCINE		3 doses through age 26 years	SHOULD NOT GET VACCINE		3 doses	post-HSCT* recipients only
HIV: CD4 count less than 200						1 or more doses							
HIV: CD4 count 200 or greater		1 dose of Tdap		1 dose									
Kidney disease or poor kidney function	Flu vaccine every year	followed by Td booster every 10 years			1–2 doses			3 doses through age 26 years	3 doses through age 21 years	2 doses	2 doses	3 doses	1 or 3 doses
Asplenia (if you do not have a spleen or if it does not work well)			1 dose for those 60 years or older			1 or more doses	1 or 2 doses					3 doses	1 or 3 doses
Heart disease Chronic lung disease Chronic alcoholism													1 or 3 doses
Diabetes (Type 1 or Type 2)				1 dose		1 or more doses						3 doses	
Chronic Liver Disease											2 doses		

More Information: There are several flu vaccines available. Talk to your healthcare professional about which flu vaccine is right for you.

*If you are pregnant, you should get a Tdap vaccine during the 3rd trimester of every pregnancy to help protect your babies from pertussis (whooping cough).

You should get zoster vaccine even if you've had shingles before.

There are two different types of pneumococcal vaccine: PCV13 (conjugate) and PPSV23 (polysaccharide). Talk with your healthcare professional to find out if one or both pneumococcal vaccines are recommended for you.

Your healthcare professional will let you know how many doses you need.

Recommended for you if you did not get it when you were a child.

If you were born in 1957 or after, and don't have a record of being vaccinated or having had measles, mumps and rubella, talk to your healthcare professional about how many doses you may need.

There are two HPV vaccines but only one HPV vaccine (Gardasil®) should be given to men.

If you are a male 22 through 26 years old and have sex with men you should complete the HPV vaccine series if you have not already done so.

Your healthcare professional will let you know how many doses you need.

*Hematopoietic stem cell transplant

(b)

Recommended For You: This vaccine is recommended for you *unless* your healthcare professional tells you that you cannot safely receive it or that you do not need it.

May Be Recommended For You: This vaccine is recommended for you if you have certain other risk factors due to your age, health, job, or lifestyle that are not listed here. Talk to your healthcare professional to see if you need this vaccine.

YOU SHOULD NOT GET THIS VACCINE

If you are traveling outside the United States, you may need additional vaccines.
Ask your healthcare professional about which vaccines you may need at least 6 weeks prior to your travel.

For more information, call 1-800-CDC-INFO (1-800-232-4636) or visit www.cdc.gov/vaccines

U.S. Department of Health and Human Services
Centers for Disease Control and Prevention

CS251118

FIGURE 51-10 Adult immunization schedule (a) by age and (b) by health condition.

28 to 30 days later. Because HBV-Ig is made from human serum, it causes relatively few adverse reactions. Another example is a patient who may have been exposed to tetanus (lockjaw) organisms as the result of an injury such as a

puncture wound. This patient may receive tetanus immune globulin (T-Ig, a human product) or tetanus antitoxin. Because tetanus antitoxin is made from horse serum, it may cause serious reactions in patients who are allergic to horses or horsehair.

For every vaccine in your medical office, you must be familiar with the indications, contraindications, dosages, administration routes, potential adverse reactions, and methods of storage and handling. You must carefully read the package insert provided with each vaccine and, when necessary,

consult drug reference books for further information. Knowledge of correct administration techniques is required and will be discussed in the *Medication Administration* chapter.

PROCEDURE 51-1 Helping the Licensed Practitioner Comply with the Controlled Substances Act of 1970

WORK // DOC

Procedure Goal: To comply with the Controlled Substances Act of 1970

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: DEA Form 224, DEA Form 224a, DEA Form 222, DEA Form 41 (available in the workbook that accompanies this textbook or online at the US Department of Justice's website), computer or pen

Method:

1. Use DEA Form 224 to register the practitioner with the Drug Enforcement Administration. Be sure to register each office location at which the practitioner administers or dispenses drugs covered under Schedules II through V. Renew all registrations every 3 years using DEA Form 224a. Form 224 can be printed from the US Department of Justice website. The renewal application (Form 224a) can be completed through registration at this site.
2. Order Schedule II drugs using DEA Form 222, as instructed by the practitioner. (Stocks of these drugs should be kept to a minimum.)

RATIONALE: *Accurate instruction from the practitioner is necessary to ensure safety.*

3. Include the practitioner's DEA registration number on every prescription for a drug in Schedules II through V.

RATIONALE: *The DEA number is required or prescriptions will not be accepted.*

4. Complete an inventory of all drugs in Schedules II through V every 2 years (as permitted in your state; this task may be reserved for other healthcare professionals).
 5. Store all drugs in Schedules II through V in a secure, locked safe or cabinet (as permitted in your state).
- RATIONALE:** *To prevent theft.*
6. Keep accurate dispensing and inventory records for at least 2 years.
 7. Dispose of expired or unused drugs according to the DEA regulations. Always complete DEA Form 41 when disposing of controlled drugs.

PROCEDURE 51-2 Interpreting a Prescription

WORK // DOC

Procedure Goal: To read and accurately interpret a prescription

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Prescription (use Figure 51-9), Table 51-4, and a method of recording (pen or electronic)

Method:

1. Verify the prescriber information. This is especially important in a multiphysician practice or electronic health record.

2. Ensure that patient information is accurate, including correct spelling of name, date of birth, and address. For written prescriptions, check legibility.
3. Confirm the date of the prescription.
4. Check the medication name and double-check spelling.
5. Verify that instructions to the pharmacist are complete and include refill authorization and generic substitution.
6. Interpret the instructions to the patient using abbreviations found in Table 51-4.
7. Make sure that the prescription is signed in ink for handwritten prescriptions and digitally for electronic prescriptions.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
51.1 Identify the medical assistant's role in pharmacology.	The role of the medical assistant in pharmacology includes being attentive to ensure that the licensed practitioner is aware of all medications, both prescription and OTC, that a patient is taking; asking each patient about alcohol and recreational drug use (both past and present), as well as herbal remedies; assisting in managing and renewing medication prescriptions; and educating the patient, using guidelines provided by the licensed practitioner, about the purpose of a drug and how to take the drug for maximum effectiveness and minimum adverse reactions.
51.2 Recognize the five categories of pharmacology and their importance to medication administration.	The five categories of pharmacology are pharmacognosy, pharmacokinetics, pharmacodynamics, pharmacotherapeutics, and toxicology. It is important to understand each of these in order to carry out the medical assistant's role in pharmacology.
51.3 Differentiate the major drug categories, drug names, and their actions.	Drug categories are sometimes named based on their action; for example, anticonvulsants are used to treat convulsions (seizures). The major drug categories and their actions are outlined in Table 51-1.
51.4 Classify over-the-counter (OTC), prescription, and herbal drugs.	Nonprescription drugs, including herbal and OTC drugs, can be obtained without a licensed practitioner's order. For prescription drugs, patients must have an authorized prescriber's written (or oral) order.
51.5 Use credible sources to obtain drug information.	Credible sources for drug information are the <i>Physicians' Desk Reference® (PDR)</i> , <i>United States Pharmacopeia/National Formulary</i> , and <i>American Hospital Formulary Service (AHFS®)</i> . You also may access medication information from package inserts, drug labels, and reliable Internet sites.
51.6 Carry out the procedure for registering or renewing a physician with the Drug Enforcement Administration (DEA) for permission to administer, dispense, and prescribe controlled drugs.	The medical assistant should assist the licensed practitioner with registration, renewal, and ordering of controlled substances, as outlined in the Controlled Substances Act of 1970 and Procedure 51-1.
51.7 Identify the parts of a prescription, including commonly used abbreviations and symbols.	A prescription must be complete to be filled. The medical assistant must be able to interpret a prescription in order to manage new and refilled medications. Procedure 51-2 and Table 51-4 will assist the medical assistant in performing these tasks.
51.8 Discuss nonpharmacologic treatments for pain.	Multiple nonpharmacologic methods are used to treat pain, including CAM therapies such as massage, yoga, biofeedback, chiropractic, acupuncture, magnetic therapy, hypnotism, and glucosamine chondroitin.
51.9 Describe how vaccines work in the immune system.	Immunizations usually contain killed or weakened organisms. When given, they stimulate the body to build up a resistance to the organism. They are used to provide immunity against specific diseases.

CASE STUDY CRITICAL THINKING

© Rubberball/Getty Images RF

Recall Kaylyn Haddix, RMA (AMT), from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. Detail the steps Kaylyn should take to design and implement an inventory system.
2. What are some credible sources of drug information Kaylyn can use to complete her task?
3. Why is Kaylyn's attention to detail a critical skill for managing the office sample drug inventory and office medications?

EXAM PREPARATION QUESTIONS

1. (LO 51.3) Which drug may prevent an asthma attack?
 - a. ProAir HFA[®]
 - b. Elavil[®]
 - c. Lovenox[®]
 - d. Levaquin[®]
 - e. Lipitor[®]
2. (LO 51.5) Which source of medication information is divided into six major sections?
 - a. *American Hospital Formulary Service (AHFS[®])*
 - b. *United States Pharmacopeia/National Formulary*
 - c. *Physicians' Desk Reference[®] (PDR)*
 - d. Epocrates[®]
 - e. RXList.com
3. (LO 51.6) Which of the following medications has the highest potential for addiction?
 - a. Lomotil[®]
 - b. Vicodin[®]
 - c. Valium[®]
 - d. Demerol[®]
 - e. Ambien[®]
4. (LO 51.6) What method is used for disposing of controlled drugs?
 - a. Discard drugs; then complete DEA Form 41
 - b. Use the disposal company that takes your biohazardous waste
 - c. Turn drugs over to a larger healthcare facility
 - d. Complete DEA Form 41 and call the DEA for disposal instructions
 - e. Complete DEA Form 222; then dispose of drugs with biohazardous waste
5. (LO 51.4) An example of an OTC medication is
 - a. Glucophage[®]
 - b. Lasix[®]
 - c. Coumadin[®]
 - d. Lipitor[®]
 - e. Prevacid[®]
6. (LO 51.7) The *Sig* line of a prescription reads "i tab po bid" What does it mean?
 - a. Take 1 tablet by mouth twice a day
 - b. The order is not accurate and cannot be used
 - c. Take 1 tablet by mouth daily
 - d. Take ½ tablet daily
 - e. Take daily 1 tablet
7. (LO 51.8) A patient would like to know more about non-pharmacologic treatments for pain. Which of the following would you *least* likely discuss with this patient?
 - a. Massage therapy
 - b. Biofeedback therapy
 - c. Acupuncture
 - d. Glucosamine chondroitin
 - e. Opioids
8. (LO 51.1) Which of the following would *least* likely be the medical assistant's role?
 - a. Make sure the licensed practitioner is aware of all medications a patient is taking
 - b. Ask each patient about alcohol and recreational drug use
 - c. Prescribe and dispense certain medications
 - d. Manage and renew medication prescriptions
 - e. Educate the patient according to licensed practitioner guidelines
9. (LO 51.9) Which of the following is made from micro-organisms and administered to a person to produce reduced sensitivity to an infectious disease?
 - a. Controlled substance
 - b. Immunity
 - c. Vaccine
 - d. Antibiotic
 - e. Pharmaceutical
10. (LO 51.2) Which of the following is the category of pharmacology that is also called *clinical pharmacology*?
 - a. Pharmacodynamics
 - b. Pharmacognosy
 - c. Pharmacokinetics
 - d. Pharmacotherapeutics
 - e. Toxicology

connect[®]

Go to CONNECT to see a video exercise about Managing a Prescription Refill.

Recall Kaylyn Haddix from the case study at the beginning of the chapter. Once Kaylyn finished her organization of the drugs at BWW, she received compliments from Malik, and he even gave her a small raise. She was so excited that at dinner one night with a group of friends she mentioned how she had organized the drug inventory at work and that she had gotten a raise. Someone at the table said, "Hey, can you get me some drugs?" Later, the same person, whom Kaylyn did not know very well, asked what kind of drugs she was working with and explained how she had a lot of trouble getting enough

medication for her back pain. What should Kaylyn say or do in this situation?

Go to PRACTICE MEDICAL OFFICE and complete the module Clinical - Privacy and Liability.

Dosage Calculations

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Chris Matthews	11/19/20XX	NKA
PATIENT INFORMATION	Attending	MRN	Other Information
	Alexis N. Whalen, MD	324-95-786	Home-schooled. Parents have refused immunizations.

Seven-year-old Chris's mother brings him to the clinic today because he has a sore throat and has had a fever since yesterday. Although Chris is home-schooled, he went to a friend's birthday party last week. According to the friend's mother, her son is displaying similar symptoms. You check and record Chris's vital signs as follows: BP 110/64, T 101.8,

© McGraw-Hill Education

P 96, R 20, Ht. 48 inches, and Wt. 49.5 lb. During the physical exam, the physician notes that Chris's lymph nodes are swollen and he has some drainage from the tonsillar area. She orders a rapid strep test, which is positive, and diagnoses streptococcal pharyngitis. She writes a prescription for an antibiotic and tells Chris to take it easy until his symptoms subside.

Keep Chris Matthews in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 52, you will be able to:

- 52.1** Explain the role of the medical assistant to ensure safe dosage calculations.
- 52.2** Identify systems of measurements and their common uses.
- 52.3** Convert among systems of measurements.
- 52.4** Execute dosage calculations accurately.
- 52.5** Calculate dosages based on body weight and body surface area.

KEY TERMS

- | | |
|-----------------------------------|-----------------------|
| amount to administer (<i>A</i>) | metric system |
| apothecary system | nomogram |
| body surface area (BSA) | proportion method |
| desired dose (<i>D</i>) | proportions |
| dose on hand (<i>H</i>) | quantity (<i>Q</i>) |
| formula method | volume |
| household system | weight |

- II.C.1** Demonstrate knowledge of basic math computations
- II.C.2** Apply mathematical computations to solve equations
- II.C.3** Define basic units of measurement in:
 - (a) the metric system
 - (b) the household system
- II.C.4** Convert among measurement systems
- II.C.5** Identify abbreviations and symbols used in calculating medication dosages
- II.P.1** Calculate proper dosages of medication for administration

6. Pharmacology

- b. Demonstrate accurate occupational math and metric conversions for proper medication administration

9. Clinical Procedures

- j. Make adaptations with patients with special needs

► Introduction

Depending on the facility and state where you work as a medical assistant, you may be called on to administer medications. All aspects of this skill require close attention to detail for the safety of the patient. Before you administer a drug, you may need to calculate the dose prescribed by the licensed practitioner. You should also be familiar with the equipment you will be using. You must execute all dosage calculations carefully and accurately in order to prevent medication errors. To do so, you must perform basic math, understand various systems of measurement, and be able to convert from one measurement system to another or within a system. You also may need to know calculations for special patient populations. This chapter will provide the basics of safe dosage calculations. Remember to check the scope of practice in your state and at your place of employment before working with dosages.

► Ensuring Safe Dosage Calculations

LO 52.1

In order to calculate dosages, you must understand and be able to perform basic math accurately. Whether you are using a calculator or doing it by hand, accuracy is key. Remember that a minor mistake in basic math can mean major errors in the patient's medication. When you perform any calculation, think about the answer you obtain and determine if it is reasonable.

Consider this example: While performing a calculation, a medical assistant adds the following numbers: $21\frac{3}{4}$, $12\frac{1}{2}$, and $1\frac{1}{2}$. He calculates an answer of $49\frac{1}{4}$. Before he accepts this answer as correct, however, he asks himself, "Is this reasonable?" In order to answer this question, he does a quick estimation. First, he adds the whole numbers from each of the mixed numbers in the problem: $21 + 12 + 1 = 34$. Then he rounds each mixed number up to a whole number and

adds them: $22 + 13 + 2 = 37$. He recognizes that the correct answer to the problem must be between 34 and 37, so his original answer is incorrect. He probably entered one of the numbers into his calculator incorrectly. When he repeats the original calculation, he now comes up with an answer of $35\frac{3}{4}$. This is between the values that he expected based on his estimate, so it is a reasonable answer to the problem.

Think about the example. When performing calculations, there are many steps in which an error might be made. In this case, a number had been entered incorrectly into a calculator. While errors like this can happen to anyone, they can usually be detected by performing a quick check to see if the answer

POINTS ON PRACTICE

Math Review

Recall the following math rules while performing dosage calculations.

- 1. Order of operations:** When solving a math problem, first divide or multiply from left to right; then add or subtract from left to right. For example, for the equation $\frac{650}{325} \times 3 = x$, you would need to divide 650 by 325 first. This equals 2.
 $x = 2 \times 3$
 Multiply second: $= 6$.
- 2. Proportions:** Proportions are two fractions that are equal to each other. When 3 of the 4 values in a proportion are known, the unknown value can be calculated. Proportions using fractions are solved by cross multiplying. For example, to solve for the unknown in $\frac{2}{3} = \frac{x}{12}$, cross multiply ($3 \times x = 2 \times 12$) and then solve for the unknown ($3 \times x = 24$; divide both sides by 3; $x = 8$).

CAUTION: HANDLE WITH CARE

Working with Decimals

Consider the following when working with decimals to prevent errors in dosage calculations.

1. Writing decimals

- Write the whole-number part of the decimal to the left of the decimal point.
- Write the decimal fraction part to the right of the decimal point. Decimal fractions are equivalent to fractions that have denominators of 10, 100, 1,000, and so forth.
- Use zero as a placeholder to the right of the decimal point just as you use zero for whole numbers. The decimal number 1.203 represents 1 ones, 2 tenths, 0 hundredths, and 3 thousandths.

2. Using zeros

- Always write a zero to the left of the decimal point when the decimal number has no whole-number part. Using the zero makes the decimal point more noticeable.

- Never place a zero after the last nonzero digit to the right of the decimal point when working with medication dosages. These “trailing zeros” can be misinterpreted and cause medication errors.

3. Rounding decimals

- Underline the place value to which you want to round.
- Look at the digit to the right of this target place value. If this digit is 4 or less, do not change the digit in the target place value. If this digit is 5 or more, round the digit in the target place value up one unit. For example, to round 2.7384 to the hundredths place, underline the 3, which is in the hundredths place. The digit to the right of the 3 is 8, which is greater than 5, so you round the number up to 2.74.
- Drop all digits to the right of the target place value.

is reasonable. You should develop the habit of asking yourself the same question *every time you perform a calculation*. When performing a calculation, analyze the problem and try to estimate a reasonable range for the answer. This critical thinking skill can help you to detect errors and should become a part of every calculation you perform.

Safe dosage calculations also depend on your understanding of basic math calculations. Refer to the *Points on Practice feature*: Math Review for a quick refresher on some important math concepts.

Measurement Systems LO 52.2

The three systems of measurement used in the United States for pharmacology and drug administration are the metric, apothecary, and household systems. Metric is the most commonly used system. Although apothecary and household systems are rarely used, you may need a basic knowledge of these systems.

To understand drug measurement, focus primarily on remembering the basic unit of volume and weight. **Volume** refers to the amount of space a drug occupies. **Weight** refers to its heaviness. Length, which is also a basic unit, is discussed in the *Vital Signs and Measurements* chapter.

Metric System

Like the decimal system, the **metric system** is based on multiples of 10. The greater your confidence working with decimals, the more comfortable you will be working with metric units. See the *Caution: Handle with Care* feature Working with Decimals. The basic units of volume and weight in the decimal-based metric system are liters (L) to measure volume and grams (g) to measure weight. Prefixes are added to these basic units of measurement to indicate multiples, such as kilogram (kg), or fractions, such as milliliter (mL) or microgram (mcg). Common metric units and equivalents are presented in Table 52-1. Note that a cubic centimeter (cc) is the amount of space occupied by 1 mL. Although these two measurements are equal, the accepted medical abbreviation is mL. Do not use the abbreviation “cc,” even though you may sometimes see it in practice. Additionally, note that the abbreviation for liters is a capital L instead of a small l. The small l can be confused with the numeral 1.

Apothecary and Household Systems

Although the metric system is preferred for dosage calculations, as a medical assistant you should have basic knowledge of the much older apothecary system, as well as the commonly known **household system**. The **apothecary system** uses units such as fluid ounces, fluid drams, pints, and quarts for volume,

TABLE 52-1 Common Metric Units					
Prefix	Kilo-	Base Unit	Centi-	Milli-	Micro-
Value	× 1,000	—	÷ 100	÷ 1,000	÷ 1,000,000
Weight	kilogram (kg) 1,000 g	gram (g) 1 g	centigram (cg) 0.01 g	milligram (mg) 0.001 g	microgram (mcg) 0.000001 g
Volume	kiloliter (kL) 1,000 L	liter (L) 1 L	centiliter (cL) 0.01 L	milliliter (mL) 0.001 L	microliter (mcL) 0.000001 L

TABLE 52-2 Apothecary Units and Equivalents

Apothecary Units	Equivalents
Measures of Volume	
8 fluid drams (fl dr) =	1 fluid ounce (fl oz)
16 fl oz =	1 pint (pt)
2 pt =	1 quart (qt)
4 qt =	1 gallon (gal)
Measures of Weight	
60 gr =	1 dram (dr)
8 dr =	1 ounce (oz)
16 oz =	1 pound (lb)

TABLE 52-3 Household Units and Equivalents

Household Units	Equivalents
Measures of Volume	
60 drops* (gtt) =	1 teaspoon (tsp)
3 tsp =	1 tablespoon (tbsp)
6 tsp =	1 ounce (oz) or 2 tbsp
8 fl oz =	1 cup (c)
2 c =	1 pint (pt)
4 c =	1 quart (qt) or 2 pt

*Droppers may vary.

and drams, ounces, and pounds for weight. The only household units used for measurement are units of volume. They include drops, teaspoons, tablespoons, ounces, cups, pints, quarts, and gallons. Keep in mind that similar units of measurement in both the apothecary and the household systems are equal: An apothecary ounce equals a household ounce. Apothecary and household units and equivalents you may come across in practice are outlined in Table 52-2 and Table 52-3.

► Conversions Within and Between Measurement Systems

LO 52.3

Frequently, you will need to convert units of measure within or between systems of measurement. Most commonly, you will convert within the metric system. For example, you may need to determine how many milligrams of medication to give a patient when the medication only comes in grams. Sometimes you may need to convert from one measurement system to another. For example, a patient may need to take 5 milliliters of medication and the only measuring device she has is a teaspoon.

Converting Within the Metric System

Converting one metric unit of measurement to another is similar to multiplying and dividing decimal numbers. When you convert a quantity from one unit of metric measurement to another, you should follow these rules:

1. Move the decimal point to the right when you convert from a larger to a smaller unit. This is dividing.

FIGURE 52-1 Use the metric steps to convert between units in the metric system.

2. Move the decimal point to the left when you convert from a smaller to a larger unit. This is multiplying.

Use Table 52-1 and Figure 52-1 to help determine both the direction and the number of places to move the decimal point when you convert between units of metric measurement. For example, milliliter is three decimal places to the right of liter, the basic unit. To convert a quantity from liters (larger) to milliliters (smaller), move the decimal point three places to the right, or three steps down the stairs shown in Figure 52-1. Similarly, to convert a quantity from grams (smaller) to kilograms (larger), move the decimal point three places to the left, or three steps up the stairs.

Let's try these examples.

Example A You need to change the patient's weight from grams to kilograms to determine how much medication should be given based on the patient's weight. An infant weighs 9,600 grams (g). How many kilograms (kg) does she weigh? A gram is smaller than a kilogram, so you need to move the decimal point to the left three steps, or divide by 1,000.

$$9,600 \text{ g} \div 1,000 = 9.6 \text{ kg}$$

Example B The physician orders a patient to have a 1-gram dose of amoxicillin. The medication is supplied in 1,000-mg tablets. You will need to determine how many milligrams are in a gram. A gram is larger than a milligram, so you need to move the decimal point to the right three steps, or multiply by 1,000.

$$1,000 \text{ gram} \times 1,000 = 1,000 \text{ mg}$$

Your Turn A patient takes a daily dose of Synthroid® 100 mcg (micrograms). How many mg (milligrams) does he take?

TABLE 52-4 Common Equivalent Measures for the Metric, Apothecary, and Household Systems*

1 teaspoon = 5 mL	1 tablespoon = 15 mL	1 fl oz = 30 mL
1 pint = 480 mL	1 kg = 2.2 lb	1 fl oz = 2 tbsp

*Equivalent measures are approximates.

First determine how many mg are in a mcg. A microgram is smaller than a milligram, so you need to move the decimal point to the left three steps, or divide by 1,000. The answer is 0.1 mg.

Converting Between Systems of Measurement

When performing dosage calculations, sometimes it will be necessary to convert units from one system to another. In order to do this, you must become familiar with their equivalent measures. Because of the difference in basic units of measure, you must remember that conversions between systems are only approximate equivalents. If you use a conversion chart, read it carefully before administering a drug. Check it several times and place a ruler under the line you are reading to be absolutely sure you are reading the chart properly. Table 52-4 provides equivalent measures for the metric, apothecary, and household systems.

In some cases, you may need to convert between systems of measurement by doing a calculation. You can use the **proportion method** to calculate these conversions. Let's try these examples.

Example A Suppose the licensed practitioner orders 10 milliliters (mL) of Benadryl® elixir. However, there is only a teaspoon (tsp) available to measure the dose. To make this conversion, follow these steps.

1. Set up a fraction with the ordered dose on the top and the unknown amount on the bottom:

$$\frac{10 \text{ mL}}{x}$$

2. Next set up a fraction with the standard equivalent. See Table 52-4. Make sure that for this fraction you use units of measure on the top and the bottom that match the units of measure on the top and the bottom of the first fraction:

$$\frac{5 \text{ mL}}{1 \text{ tsp}}$$

3. Then set up a proportion with both fractions:

$$\frac{10 \text{ mL}}{x} = \frac{5 \text{ mL}}{1 \text{ tsp}}$$

4. Now cross multiply. Multiply the bottom left number by the top right number, and multiply the top left number by the bottom right number:

$$x \times 5 \text{ mL} = 10 \text{ mL} \times 1 \text{ tsp}$$

5. To solve for x , divide both sides of the equation by 5 mL; then do the arithmetic, canceling out like terms in the top and bottom of each fraction:

$$\frac{x \times 5 \text{ mL}}{5 \text{ mL}} = \frac{10 \text{ mL} \times 1 \text{ tsp}}{5 \text{ mL}}$$

$$x = 2 \text{ tsp}$$

Example B Suppose the medication is ordered based on the patient's weight in kilograms. You know the patient's weight is 168 lb. To make this conversion, follow these steps:

1. Set up a fraction with the weight in pounds on top and the unknown weight in kilograms on the bottom:

$$\frac{168 \text{ lb}}{x \text{ kg}}$$

2. Next set up a fraction with the standard equivalent. See Table 52-4. Make sure that for this fraction you use units of measure on the top and the bottom that match the units of measure on the top and the bottom of the first fraction:

$$\frac{2.2 \text{ lb}}{1 \text{ kg}}$$

3. Then set up a proportion with both fractions:

$$\frac{168 \text{ lb}}{x \text{ kg}} = \frac{2.2 \text{ lb}}{1 \text{ kg}}$$

4. Now cross multiply. Multiply the bottom left number by the top right number, and multiply the top left number by the bottom right number:

$$x \times 2.2 \text{ lb} = 168 \text{ lb} \times 1 \text{ kg}$$

5. To solve for x , divide both sides of the equation by 2.2 lb; then do the arithmetic, canceling out like terms in the top and bottom of each fraction and then dividing 168 by 2.2:

$$\frac{x \times \cancel{2.2 \text{ lb}}}{\cancel{2.2 \text{ lb}}} = \frac{168 \cancel{\text{ lb}} \times 1 \text{ kg}}{2.2 \cancel{\text{ lb}}}$$

$$x = 76.36 \text{ kg}$$

Your Turn You need to prepare a solution for the licensed practitioner to clean a wound. He asks for 3½ fluid ounces (fl oz) of saline to be placed in sterile bowl. Your container of saline is marked in milliliters (mL). Use these steps to make the conversion:

1. Set up a fraction with the ordered dose on the top and the unknown amount on the bottom.
2. Next, set up a fraction with the standard equivalent. See Table 52-4. Make sure that for this fraction you use units of measure on the top and the bottom that match the units of measure on the top and the bottom of the first fraction.
3. Then set up a proportion with both fractions.
4. Now cross multiply. Multiply the bottom left number by the top right number, and multiply the top left number by the bottom right number.
5. To solve for x , cancel out like terms in the top and bottom of each fraction, then do the arithmetic.

If you followed each step correctly, you find that you need 105 mL of saline.

► Dosage Calculations

LO 52.4

As a medical assistant, you may be called on to calculate medication doses. Remember to follow your scope of practice. You may be able to calculate these using either the proportion

method or a **formula method**. No matter which method you use, you must be aware that the patient's health or life can depend on your calculations. Always take the time to check and recheck your arithmetic. If you have a question or you are not sure about your calculations, check them again and then have a coworker check. If you are not 100% sure you know how to do dosage calculations correctly, consider buying and using a dosage calculation workbook or searching the Internet for extra practice.

Proportion Method for Dosage Calculations

The proportion method described earlier in the chapter for unit conversion also can be used to perform dosage calculations. Let's try some examples.

Example A Suppose the doctor orders 500 mg of ampicillin, but each tablet contains only 250 mg. To calculate how to provide this dose, follow these steps:

1. Set up a fraction with the amount of the drug ordered over the unknown (in this case, the number of tablets).

$$\frac{500 \text{ mg}}{x \text{ tab}}$$

2. Next, set up a fraction with the amount of drug in a single tablet (dose on hand) over 1 tablet (dosage unit).

$$\frac{250 \text{ mg}}{1 \text{ tab}}$$

3. Now set up the proportion with both fractions, making sure the same units of measure are on the top and bottom of each side of the proportion.

$$\frac{500 \text{ mg}}{x \text{ tab}} = \frac{250 \text{ mg}}{1 \text{ tab}}$$

4. Cross multiply. Multiply the bottom left number by the top right number, and multiply the top left number by the bottom right number:

$$x \text{ tab} \times 250 \text{ mg} = 500 \text{ mg} \times 1 \text{ tab}$$

5. To solve for x , divide both sides of the equation by 250 mg; then do the arithmetic, canceling out like terms in the top and bottom of each fraction:

$$\begin{aligned} \frac{x \times 250 \text{ mg}}{250 \text{ mg}} &= \frac{500 \text{ mg} \times 1 \text{ tab}}{250 \text{ mg}} \\ x &= \frac{500 \text{ tab}}{250} \\ x &= 2 \text{ tab} \end{aligned}$$

The patient will receive 2 tablets.

Example B The doctor orders 30 mg of Adalat®, but each capsule (cap) contains only 10 mg. To calculate the prescribed drug dose using the proportion method, you would follow these steps:

1. Set up a fraction with the amount of the drug ordered over the unknown amount (in this case, the number of capsules).

$$\frac{30 \text{ mg}}{x \text{ cap}}$$

2. Next set up a fraction with the amount of drug in a single capsule (dose on hand) over 1 capsule (dosage unit).

$$\frac{10 \text{ mg}}{1 \text{ cap}}$$

3. Now set up the proportion using both fractions, making sure the same units of measure are on the top and bottom of each side of the proportion.

$$\frac{30 \text{ mg}}{x \text{ cap}} = \frac{10 \text{ mg}}{1 \text{ cap}}$$

4. Cross multiply. Multiply the bottom left number by the top right number, and multiply the top left number by the bottom right number:

$$x \text{ cap} \times 10 \text{ mg} = 30 \text{ mg} \times 1 \text{ cap}$$

5. To solve for x , divide both sides of the equation by 10 mg; then do the arithmetic, canceling out like terms in the top and bottom of each fraction:

$$\begin{aligned} \frac{x \times 10 \text{ mg}}{10 \text{ mg}} &= \frac{30 \text{ mg} \times 1 \text{ cap}}{10 \text{ mg}} \\ x &= \frac{30 \text{ cap}}{10} \\ x &= 3 \text{ cap} \end{aligned}$$

The patient will receive 3 capsules.

Example C Now let's try a liquid medication. The licensed practitioner wants a patient to have 375 mg of valproic acid. You have on hand a bottle of valproic acid oral solution. See the label in Figure 52-2. Follow these steps:

1. Set up a fraction with the amount of the drug ordered over the unknown amount (in this case, the amount of liquid in mL).

$$\frac{375 \text{ mg}}{x \text{ mL}}$$

2. Next set up a fraction with the amount of drug in a single dose (dose on hand) over the number of mL in a single dose (dosage unit).

$$\frac{250 \text{ mg}}{5 \text{ mL}}$$

3. Now set up the proportion using both fractions, making sure the same units of measure are on the top and bottom of each side of the proportion.

$$\frac{375 \text{ mg}}{x \text{ mL}} = \frac{250 \text{ mg}}{5 \text{ mL}}$$

FIGURE 52-2 Valproic acid oral solution.

4. Cross multiply. Multiply the bottom left number by the top right number, and multiply the top left number by the bottom right number:

$$x \times 250 \text{ mg} = 375 \text{ mg} \times 5 \text{ mL}$$

5. To solve for x , divide both sides of the equation by 250 mg; then do the arithmetic, canceling out like terms in the top and bottom of each fraction and then multiplying 375×5 and dividing by 250:

$$\begin{aligned} \frac{x \times 250 \text{ mg}}{250 \text{ mg}} &= \frac{375 \text{ mg} \times 5 \text{ mL}}{250 \text{ mg}} \\ x &= \frac{375 \times 5 \text{ mL}}{250} \\ x &= 7.5 \text{ mL} \end{aligned}$$

The patient will receive 7.5 mL of medication.

Your Turn The physician has ordered diazepam 4 mg by mouth. You have on hand the bottle of diazepam shown in Figure 52-3. Follow the steps below to determine how much medicine the patient should receive.

1. Set up a fraction with the amount of the drug ordered over the unknown (in this case, the number of tablets).
2. Next, set up a fraction with the amount of drug in a single tablet (dose on hand) over 1 tablet (dosage unit).
3. Now set up the proportion with both fractions, making sure the same units of measure are on the top and bottom of each side of the proportion.
4. Cross multiply. Multiply the bottom left number by the top right number, and multiply the top left number by the bottom right number.
5. To solve for x , cancel out like terms in the top and bottom of each fraction, then do the arithmetic.

If you did the problem correctly, you will discover that the patient needs 2 tablets.

Formula Method for Dosage Calculations

In some instances, you can use a basic formula to calculate drugs that have the same units as the dose ordered—such as milligrams and milligrams—and therefore do not require a conversion. When you use the formula method, you substitute the correct numbers for what each of the letters

represents. The basic formula that you would use looks like this:

$$A = \frac{D}{H} \times Q$$

Using this formula, you will need to know the following:

A = **Amount to administer** (the amount of medication the patient will receive)

D = **Desired dose** (the amount of medication the licensed practitioner has ordered the patient to take)

H = **Dose on hand** (the amount of medication in each unit of the drug—for example, the number of mcg, mg, or g in each unit dose)

Q = **Quantity** of the dose on hand or dosage unit—for example, a pill or an amount of liquid

Let's try some examples.

Example A Suppose that the licensed practitioner orders acetaminophen 650 milligrams (mg). This is the desired dose (D). However, all that the office has on hand are 325 mg Tylenol® tablets. The dose on hand (H) is 325 mg, and the quantity (Q) or dosage unit is 1 tablet, because the dose on hand (325 mg) is given per tablet. Follow these steps to perform the calculation:

1. Use the formula, inserting each number, and label all the parts:

$$\begin{aligned} A &= \frac{D}{H} \times Q \\ A &= \frac{650 \text{ mg}}{325 \text{ mg}} \times 1 \text{ tablet} \end{aligned}$$

2. Cancel and solve:

$$\begin{aligned} A &= \frac{650 \text{ mg}}{325 \text{ mg}} \times 1 \text{ tablet} \\ A &= \frac{650}{325} \times 1 \text{ tab} \\ A &= 2 \text{ tablets} \end{aligned}$$

Two tablets need to be given to the patient. See the *Medication Administration* chapter for the correct procedure for administering a medication.

Example B Now let's say the licensed practitioner asks you to administer 10 mg of Compazine® by injection. The desired dose (D) is 10 mg. According to the Compazine®

FIGURE 52-3 Diazepam tablets.

CAUTION: HANDLE WITH CARE

Preventing Errors During Dosage Calculations

Medication errors are a serious problem in healthcare. Always pay close attention to the dose and the route of administration (how the medication is given). You must check and recheck the ordered form of the drug as well as the amount of drug per dose of the drug. In the following example, this crucial relationship is illustrated.

Prochlorperazine (Compazine®) is an antiemetic drug for acute nausea and vomiting. It is given to both children and adults. When the vomiting is so severe that a tablet or capsule cannot be swallowed, the drug is administered in injectable or suppository form. This drug is available in multiple forms:

- 10 mL multidose vials with 5 mg of drug per mL, written as 5 mg/mL
- 2 mL single-dose vials with 5 mg/mL
- 4 fl oz bottles of syrup with 5 mg/5 mL (5 mg/1 tsp)
- 5 mg tablets
- 10 mg tablets
- 2 mL prefilled disposable syringes with 5 mg/mL
- 2½ mg suppositories
- 5 mg suppositories
- 25 mg suppositories
- 10 mg extended release capsules
- 15 mg extended release capsules

Because so many forms of this drug are available, there is a high risk of error in choosing the correct form. In addition, the route of administration determines how much drug is delivered in one dose. For example, note that suppositories are available in 2½ mg, 5 mg, and 25 mg forms. If the 2½ mg dose were written as 2.5 mg, there could be confusion with the 25 mg dose suppository. Thus, the 2½ mg suppository is always written this way, even in the *PDR*. This clarification helps prevent a child from receiving the adult dose of 25 mg, which could result in serious complications to the central nervous system. This possible confusion is one example of how much difference a decimal point can make.

Note also that in the syrup there is a 5 mg dose of drug per 5 mL (1 tsp), whereas in the other liquid forms (vials and prefilled syringes), there is a 5 mg dose of drug per 1 mL. The injectable form is five times more concentrated than the syrup. Therefore, if you were to administer the same amount of injectable liquid as syrup to a patient, you would give the patient five times more drug than in the syrup. Just as a child could be endangered with the 25 mg suppository, an adult could be endangered with the wrong form of liquid. Because elderly patients often receive syrup forms of medication, this instruction could be particularly confusing.

label, the liquid contains 5 mg/mL, which means there are 5 mg of Compazine® in every 1 mL of liquid, so 5 mg is the dose on hand (*H*) and 1 mL is the quantity (*Q*) or dosage unit. Always read the label carefully to determine the dose on hand and the quantity or dosage unit. See the *Caution: Handle with Care* feature Preventing Errors During Dosage Calculations. Follow the same steps to perform the calculation:

1. Use the formula, inserting each number in the correct place, and label all the parts:

$$A = \frac{D}{H} \times Q$$
$$A = \frac{10 \text{ mg}}{5 \text{ mg}} \times 1 \text{ mL}$$

2. Cancel and solve:

$$A = \frac{10 \text{ mg}}{5 \text{ mg}} \times 1 \text{ mL}$$
$$A = \frac{10}{5} \times 1 \text{ mL}$$
$$A = 2 \text{ mL}$$

The amount to administer to the patient is 2 mL. See the *Medication Administration* chapter for the correct procedure for administering a medication.

Example C The licensed practitioner wants a pediatric patient to have 200 mg of clarithromycin. The label of the only bottle you have on hand is pictured in Figure 52-4.

FIGURE 52-4 Clarithromycin for oral suspension.

FIGURE 52-5 Granisetron hydrochloride oral solution.

1. Use the formula, inserting each number, and label all the parts:

$$A = \frac{D}{H} \times Q$$

$$A = \frac{200 \text{ mg}}{250 \text{ mg}} \times 5 \text{ mL}$$

2. Cancel and solve:

$$A = \frac{200 \cancel{\text{mg}}}{250 \cancel{\text{mg}}} \times 5 \text{ mL}$$

$$A = \frac{200}{250} \times 5 \text{ mL}$$

$$A = 4 \text{ mL}$$

The patient should receive 4 mL of oral suspension. See the *Medication Administration* chapter for the correct procedure for administering an oral medication.

Your Turn The licensed practitioner orders 1.5 mg of granisetron hydrochloride oral solution. You have on hand the medication shown in Figure 52-5. How much medication should the patient receive?

1. Use the formula, inserting each number, and label all the parts.
2. Cancel units and solve.

The patient should receive 7.5 mL of medication. See the *Medication Administration* chapter for the correct procedure for administering an oral medication.

► Body Weight and Body Surface Area Calculations

LO 52.5

In certain cases, a drug dose is determined based on the **body surface area (BSA)** or the weight of the patient. This is more common with pediatric and geriatric patients. These patients are at greater risk of harm from medication because of the way they break down and absorb medications. Calculations for these individuals must be precise. Although BSA and weight dosage calculations are usually done by the physician or other licensed healthcare personnel, you may be asked to perform calculations, depending on your area of practice.

Dosages Based on Weight

An order based on weight often states the amount of medication per weight of the patient per unit of time. For example, an order for a 34 lb child may read “Clarithromycin 15 mg/kg/day po q12h.” This means that over the course of a day, the

patient should receive 15 mg of medication for every kilogram (kg) he or she weighs. A portion of this total amount is to be given every 12 hours, or 2 times during a 24-hour period. You will need to calculate the patient’s weight in kilograms, the total medication to administer in 24 hours, and the amount of medication to administer in each dose. Use these steps:

1. Calculate the weight in kilograms using the proportion method. For accuracy, round the results to the nearest hundredth.

- a. Set up the proportion. Recall from Table 52-4 that 2.2 lb = 1 kg.

$$\frac{34 \text{ lb}}{x \text{ kg}} = \frac{2.2 \text{ lb}}{1 \text{ kg}}$$

- b. Cross multiply. Remember to multiply the bottom left number by the top right number, and multiply the top left number by the bottom right number.

$$x \text{ kg} \times 2.2 \text{ lb} = 34 \text{ lb} \times 1 \text{ kg}$$

- c. Solve for x (the unknown).

$$x = \frac{34}{2.2} \text{ kg}$$

$$x = 15.45$$

2. Calculate the desired dose (D) for 24 hours by multiplying the dose ordered by the weight in kilograms. (Round your answer to the nearest milligram.)

$$15 \text{ mg} \times 15.45 \text{ kg} = \text{desired dose } (D) \text{ for 24 hours}$$

$$231.75 \text{ mg, rounded to } 232 \text{ mg} = D \text{ (for 24 hours)}$$

3. Calculate the amount of medication to administer in each dose. To do this, divide the amount to be administered in 24 hours by the number of times the medication will be administered in 24 hours. In this case, the medication is to be given two times in 24 hours.

$$232 \text{ mg} \div 2 = 116 \text{ mg (the desired dose for one dose)}$$

4. Calculate the amount to administer. On hand you have the medication shown in Figure 52-6.

- a. Set up the equation. You want to give 116 mg of medication, and the label shows there are 250 mg in 5 mL of medication.

$$\frac{116 \text{ mg}}{x \text{ mL}} = \frac{250 \text{ mg}}{5 \text{ mL}}$$

- b. Cross multiply. Remember to multiply the bottom left number by the top right number, and multiply the top left number by the bottom right number.

FIGURE 52-6 Clarithromycin for oral suspension.

$$x \text{ mL} \times 250 \text{ mg} = 116 \text{ mg} \times 5 \text{ mL}$$

- c. Solve for x to determine the amount of liquid medication to administer to this patient.

$$x \text{ mL} = 116 \times \frac{5}{250}$$

$$\text{mL} = 2.32$$

$$\text{mL} = 2.3 \text{ (rounded to the nearest tenth)}$$

Now that you have determined the amount, refer to the *Medication Administration* chapter before you give the medication to the patient.

Dosages Based on Body Surface Area

The total surface area of the body or body surface area (BSA) is measured in square meters (m^2). A person's BSA is used to calculate very precise medication dosages. Pediatric patients, as well as burn victims and patients undergoing chemotherapy or radiation therapy, may need BSA dosage calculations. A complex formula or a nomogram, as shown in Figure 52-7, may be used to determine the BSA. A **nomogram** is a set of scales arranged so that a ruler aligned with two of the values shows the corresponding value on the third scale. Aligning the ruler with a person's height and weight shows the body surface area. In this case, the child is 89 cm tall and weighs 13.9 kg. The line drawn between these values in the first and third columns crosses the second column at approximately 0.57, so the child's BSA is 0.57 m^2 . For a medication ordered as $30 \text{ mcg}/\text{m}^2$, this patient would receive $30 \text{ mcg} \times 0.57 = 17.1 \text{ mcg}$ of the medication.

FIGURE 52-7 A nomogram is used to determine the BSA in order to calculate a medication dose.

LEARNING OUTCOMES	KEY POINTS
52.1 Explain the role of the medical assistant to ensure safe dosage calculations.	A medical assistant must be proficient in math and determine whether the answer is reasonable for every calculation he or she performs.
52.2 Identify systems of measurements and their common uses.	The metric system is based on 10 and is the most common system of measurement for dosage calculations. Metric units commonly used for dosage calculations include g, mg, mcg, and mL. The apothecary and household systems have some equal measures, but they are used rarely.
52.3 Convert among systems of measurements.	To convert among systems of measurements, you can refer to a conversion chart or perform a proportion method calculation. Keep in mind that measurements between the metric and the apothecary and household systems are only approximations.
52.4 Execute dosage calculations accurately.	Use the proportion method or formula method to perform dosage calculations. <i>Proportion Method</i> 1. Set up a fraction with the amount of the drug ordered over the unknown amount. 2. Set up a fraction with the amount of drug in a single dose (dose on hand) over the dosage unit. 3. Set up the proportion using both fractions, making sure the same units of measure are on the top and bottom of each side of the proportion. 4. Cross multiply. 5. To solve for x, do the arithmetic; then cancel out like terms in the top and bottom of each fraction. <i>Formula Method</i> $A = \frac{D}{H} \times Q$ A = Amount to administer (the amount of medication the patient will receive) D = Desired dose (the amount of medication the licensed practitioner has ordered the patient to take) H = Dose on hand (the amount of medication in each unit of the drug) Q = Quantity of the dose on hand or dosage unit
52.5 Calculate dosages based on body weight and body surface area.	Dosages based on body weight and BSA are used when precise amounts of medication must be administered. Body weight calculations are usually ordered in mg/kg/day. BSA calculations use special formulas or a nomogram.

CASE STUDY / CRITICAL THINKING

© McGraw-Hill Education

Recall Chris Matthews from the beginning of the chapter. Now that you have completed the chapter, answer the following questions.

1. The physician ordered amoxicillin 50 mg/kg/day po q8h. What is Chris's weight in kilograms?
2. The medication on hand is amoxicillin oral suspension 200 mg per 5 mL. How much medication, in milliliters, should Chris receive for each dose?
3. Name at least three things you can do to ensure that Chris receives a safe and accurate dose of medication.

EXAM PREPARATION QUESTIONS

There may be more than one correct answer. Circle the *best* answer.

1. (LO 52.1) As a medical assistant, how can you *best* ensure safe dosage calculations?
 - a. Use a calculator for every calculation
 - b. Check with a coworker for every calculation you perform
 - c. Do not use the unit of measurement when performing calculations
 - d. Use a trailing zero after the decimal point for whole numbers
 - e. Check your calculation by determining if the results are reasonable
2. (LO 52.2) What do the following metric prefixes represent in comparison to the base unit: kilo; milli; micro?
 - a. $\times 1,000$; $\div 100$; $\div 1,000,000$
 - b. $\times 100$; $\div 1,000$; $\div 1,000,000$
 - c. $\div 1,000,000$; $\times 1,000$; $\div 1,000$
 - d. $\times 1,000$; $\div 1,000$; $\div 1,000,000$
 - e. $\div 1,000$; $\times 1,000$; $\div 1,000,000$
3. (LO 52.4) How much medication should be given if the physician ordered Keflex[®] 500 mg and you have on hand Keflex[®] 250 mg per 5 mL?
 - a. 5 mL
 - b. 250 mg
 - c. 250 mL
 - d. 10 mL
 - e. 125 mL
4. (LO 52.4) How much medication would be in the syringe if the physician ordered Decadron[®] 6 mg IM now and you have on hand Decadron[®] 4 mg per mL?
 - a. 1.5 mg
 - b. 1.5 mL
 - c. 4 mL
 - d. 1 mL
 - e. 3 mL
5. (LO 52.4) The doctor orders 5 mg of glyburide, but each tablet contains only 1.25 mg. How many tablets should the patient take?
 - a. 3
 - b. 1.25
 - c. 5
 - d. 1
 - e. 4
6. (LO 52.5) The physician has ordered gemcitabine 400 mg/m² IV for a patient whose BSA is 0.47 m². You have on hand a 200 mg vial of gemcitabine for injection that contains 38 mg per mL. How much medication should this patient receive?
 - a. 94 mg
 - b. 17.9 mL
 - c. 200 mg
 - d. 5 mL
 - e. 10.5 mL
7. (LO 52.3) The licensed practitioner orders Ceclor[®] 0.375 g PO bid. You have on hand Ceclor[®] oral suspension 187 mg per 5 mL. How many mg of Ceclor[®] are ordered?
 - a. 187
 - b. 5
 - c. 0.375
 - d. 375
 - e. 0.187
8. (LO 52.4) The licensed practitioner orders Ceclor[®] 0.375 g PO bid. You have on hand Ceclor[®] oral suspension 187 mg per 5 mL. How many mL of Ceclor[®] do you need to administer?
 - a. 10
 - b. 5
 - c. 187
 - d. 2.5
 - e. 0.375

9. (LO 52.4) The physician wants you to give the patient an IM injection of 135 mg of ceftriaxone. You have on hand the medication pictured here. How many mL of medication would you inject?
- 2 mL
 - 135 mcg
 - 0.11 mL
 - 1,000 mg
 - 1.35 mL

10. (LO 52.5) A 5-year-old child weighs 44 lb. The licensed practitioner orders him to receive Zinacef® 50 mg/kg/day IM q6h. How many milligrams of medication should the child receive in one dose?
- 1,000 mg
 - 167 mg
 - 20 kg
 - 250 mg
 - 50 mg

SOFT SKILLS SUCCESS

- The patient says she is here for a B₁₂ injection and the order reads “Cyanocobalamin 500 mcg IM now.” You have never given cyanocobalamin or a B₁₂ injection before. What should you do?
- Using the order in question 1, you find a vial of cyanocobalamin that is 1,000 mcg/mL and give the patient a 1 mL injection in the deltoid muscle of her left arm. When you get ready to chart the medication, you realize

you should have given only 0.5 mL of the medication. What should you do now?

Medication Administration

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	John Miller	12/5/19XX	Bee stings
	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	082-09-981	Seeing physical therapist 3X a week for injury.

John Miller, a 65-year-old patient, has arrived at the clinic for a return-to-work visit. He has a history of hypertension, diabetes Type 2, myocardial infarction (MI) 4 years ago, and congestive heart failure (CHF). He has been taking glyburide 2.5 mg daily, captopril 25 mg twice a day, and HCTZ 25 mg daily. He is here for a blood pressure check

© McGraw-Hill Education

and the physician wants to evaluate the medications he just started 3 months ago. He also is scheduled for a pneumococcal immunization. As you read through this chapter, think about what the medical assistant should do next and why.

Keep John Miller in mind as you study this chapter. There will be questions at the end of the chapter based on the

case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 53, you will be able to:

- 53.1** Describe rules and responsibilities regarding drug administration and the initial preparation for drug administration.
- 53.2** List the rights of drug administration.
- 53.3** Recognize the correct equipment to use for administering medications.
- 53.4** Carry out the procedures for administering oral medications.
- 53.5** Carry out procedures for administering parenteral medications by injection.
- 53.6** Carry out procedures for administering parenteral medications by other routes.
- 53.7** Relate special considerations required for medication administration to pediatric, pregnant, breast-feeding, and geriatric patients.
- 53.8** Outline patient education information related to medications.
- 53.9** Implement accurate and complete documentation of medications.

KEY TERMS

buccal	ointment
calibrated spoon	scored
diluent	solution
douche	subcutaneous (subcut)
infusion	sublingual
intra dermal (ID)	transdermal
intramuscular (IM)	triple check
intravenous (IV)	Z-track method

I.P.4 Verify the rules of medication administration:

- (a) right patient
- (b) right medication
- (c) right dose
- (d) right route
- (e) right time
- (f) right documentation

I.P.5 Select proper sites for administering parenteral medication

I.P.6 Administer oral medications

I.P.7 Administer parenteral (excluding IV) medications

II.C.5 Identify both abbreviations and symbols used in calculating medication dosages

II.P.1 Prepare proper dosages of medication for administration

V.P.4 Coach patients regarding:

- (b) health maintenance
- (c) disease prevention
- (d) treatment plan

X.C.11 Describe the process in compliance reporting:

- (a) unsafe activities
- (b) errors in patient care
- (d) incident reports

X.P.3 Document patient care accurately in the medical record

X.P.6 Report an illegal activity in the healthcare setting following proper protocol

2. Anatomy and Physiology

- c. Identify diagnostic and treatment modalities as they relate to each body system

6. Pharmacology

- a. Identify drug classification, usual dose, side effects, and contraindications of the top most commonly used medications
- d. Properly utilize Physicians' Desk Reference (PDR), drug handbook and other drug references to identify a drug's classification, usual dosage, usual side effects, and contraindications

9. Medical Office Clinical Procedures

- f. Prepare and administer oral and parenteral medications and monitor intravenous (IV) infusions

► Introduction

Drug administration is one of the most important and most dangerous duties for a medical assistant. By following the procedures for proper drug administration, you can help restore patients to health. If you calculate dosages inaccurately, measure drugs incorrectly, or administer drugs improperly, patients' medications may have no therapeutic effect, may worsen their disease or abnormal condition, or may even cause them to die.

To administer drugs safely and effectively to all patient groups, including pediatric, pregnant, and elderly patients, you must know and understand the principles of pharmacology (see the *Principles of Pharmacology* chapter) and how to perform dosage calculations (see the *Dosage Calculations* chapter). This chapter prepares you to understand the fundamentals of drug administration, including

- Rules and responsibilities of drug administration.
- Rights of drug administration.
- Routes of medication administration.
- Techniques needed to administer drugs.
- Special patient considerations.
- Patient education.

Your role may vary depending on the state and practice where you are employed. Many states have medical practice acts that define the exact duties of medical assistants in drug administration. For example, an act may specify which drugs you are allowed to administer and by which routes. Because state laws vary, you need to research the scope of practice for medical assistants in the state where you will work.

► Preparing to Administer a Drug LO 53.1

To administer drugs, you should know the uses, contraindications, interactions, and adverse effects of common drugs. You should be familiar with the medications frequently prescribed in your practice. Furthermore, to be able to assume a role in patient education, you must be comfortable with all aspects of drug administration so that you can instruct patients about the drugs prescribed to them.

Although the physician gives the order to administer a drug, the medical assistant has a lot of responsibility before a medication can be administered. As a medical assistant, you will often interview the patient. You must be alert to—and inform the licensed practitioner of—any change in the patient's condition that could affect drug therapy. Some preparation tasks

are related to the drugs and drug allergies, administration site, patient condition, and patient consent.

Drugs and Drug Allergies

Before any medication is given, the physician should be aware of the medications the patient is currently taking. As you learned in the *Principles of Pharmacology* chapter, some medications, including herbal medications, can interact in a negative way, so the physician needs to know everything the patient is taking before ordering a medication. The medical assistant is responsible for ensuring that a complete and accurate medication list is maintained on the patient's chart. This medication list must be updated every time the patient comes for an appointment. See Figure 53-1. While asking about medications, you also must ask the patient about any drug allergies. Even though you may see a patient on a regular basis, be in the habit of asking about drugs and drug allergies at every patient visit. Patients often see other physicians or specialists, who may have prescribed different medications. A patient could have had a drug reaction to a medication prescribed by another physician. If applicable, document in the patient chart "NKDA," or "no known drug allergies."

Administration Site

Drugs may be administered for either local or systemic effects. Generally, drugs that have local effects are applied directly to the skin, tissues, or mucous membranes. Drugs that produce systemic effects are administered by routes that allow the drug to be absorbed and distributed in the bloodstream throughout the body. These various routes are discussed in the Drug Routes and Equipment section of this chapter. Before you administer a drug, you must check the site of administration. For example, if you are asked to give an oral medication, you must make sure the patient can take the medication. You may ask if the patient is nauseated, can swallow a pill, or has had anything to eat or drink, depending on the medication.

For an injection, you must locate and inspect the injection site. Find the appropriate injection site by using anatomical landmarks. Inspect the skin by checking for the following conditions, which may eliminate the site:

- Moles
- Scars
- Birthmarks
- Traumatic injury
- Redness
- Rash
- Edema
- Cyanosis
- Burns
- Tattoos
- Site of a mastectomy
- Paralyzed areas
- Warts

If you are unsure about any of these conditions, inform the physician.

Patient Condition

Before administering a medication, observe the patient for any condition that might interfere with the medication you will be administering. For example, a patient who is nauseated or vomiting may not be able to swallow a pill. In addition, review the patient's drug list to ensure that any medications already being taken will not interfere with the ordered drug or route of administration. Double-check the order and ensure that it is appropriate for the patient's age and weight.

Patient Consent Form

Many physicians require that a patient sign a consent form before receiving an injection. A consent is necessary for vaccines, for example. This form provides general information regarding the medication or vaccine and lists the possible side effects or adverse effects. If a consent form is needed, make sure that the patient signs the form and that you have answered any questions prior to giving the injection.

General Rules for Drug Administration

No matter what drug or administration route is ordered, follow these general rules when administering drugs.

- Give only the drugs the physician has ordered. Written orders are preferable, but oral orders are appropriate for emergencies. If you are unfamiliar with any aspect of a drug the physician orders, consult a credible drug reference.
- Wash your hands before handling the drug. Prepare the drug in a well-lit area, away from distractions. Focus only on the task at hand.
- Perform a **triple check** by checking the medication three times. Check the medication three times even if the dose is prepackaged, labeled, and ready to be administered.

1st check—when you take it from the storage container and match it to the medication administration record (MAR)

2nd check—when you prepare it

3rd check—before you close the storage container or just before you administer the medication to the patient

- Calculate the dose if necessary. See the *Dosage Calculations* chapter. Remember, if you are unsure of your computation, ask another medical assistant or a licensed practitioner to check it.
- Avoid leaving a prepared drug unattended and never administer a drug that someone else has prepared.
- Ask the patient to state his name and date of birth to ensure correct identification. Double-check with the patient about possible drug allergies. Do not rely on documentation in his chart; he may have developed a new allergy that has not yet been added to the record.
- Be sure the physician is in the office when you administer a drug or vaccine. If the patient develops an anaphylactic reaction (sudden, severe allergic reaction) to the drug or vaccine, the physician must administer epinephrine.

(a)

(b)

FIGURE 53-1 (a) Each time a patient visits the clinic, update the medication list as needed. (b) Be certain to ask about allergies and record these in the allergy window in the electronic health record.

CAUTION: HANDLE WITH CARE

Handling Medication Errors

Medication errors are a serious, yet inevitable, problem. Great care should always be taken to prevent them. However, if an error does occur, no matter the cause, it must be reported. Immediately tell the licensed practitioner. Not reporting an error is unethical and in some cases illegal, especially if a serious consequence occurs. Most facilities require that an incident report be completed. This form documents the error. It is completed and then signed by everyone involved, as well as your supervisor. Errors also are reported online through an online program developed by the US Pharmacopeia and the Institute for Safe Medical Practices. Reporting errors at these sites provides information to assist in the prevention of errors.

- After administering the drug, ask the patient to remain in the facility for 10 to 20 minutes so that you can observe the patient for any unexpected effects, such as anaphylaxis. See the *Emergency Preparedness* chapter.
- Give the patient specific instructions about the effects of the drug as well as general information about drug use.
- If the patient refuses to take the drug, discard it according to your facility policy. Do not flush it down the toilet or return it to the original container. Be sure to document the refusal in the patient's record and tell the physician.
- If you make an error in drug administration, tell the physician immediately. See the *Caution: Handle with Care* feature Handling Medication Errors.
- Document the drug and dose immediately after administration; never document administration before giving medicine.

► Rights of Medication Administration

LO 53.2

The rights of medication administration are a set of safety checks the medical assistant must follow to prevent errors and ensure patient safety when administering medications (see

TABLE 53-1 The Rights of Medication Administration

Basic Rights	Additional Rights
1. Right patient	7. Right reason
2. Right drug	8. Right to know
3. Right dose	9. Right to refuse
4. Right route	10. Right technique
5. Right time	
6. Right documentation	

Table 53-1). The basic rights of medication administration are the following: right patient, right drug, right dose, right route, right time, and right documentation. Additional rights include right reason, right to know, right to refuse, and right technique. A violation of any of the rights constitutes a medication error.

Right Patient

Always check the name and date of birth on the order for a drug or vaccine in the patient's chart, then compare to the name and date of birth that the patient tells you. Do not call the patient by name because a forgetful or confused patient might answer to any name. Have an attending caregiver or family member state the name and date of birth if the patient is unable.

Right Drug

Carefully compare the name of the prescribed drug or vaccine in the patient's chart with the label on the drug container. As you check the drug name on the label, look at the expiration date. Never use a drug that has passed this date (Figure 53-2). If you are unfamiliar with the drug, look it up in a credible drug reference. Also, never prepare a drug from a container with a damaged or handwritten label. Always perform the triple check every time you prepare a medication.

Right Dose

Compare the dose on the order in the patient's chart with the dose you prepare. To obtain the right dose, read the label closely and calculate accurately. Do not confuse the dose contained in one tablet with the number of tablets in the container.

FIGURE 53-2 Check the label for the expiration date before administering a drug.

© McGraw-Hill Education

Right Route

Double-check to make sure the administration route you are preparing to use matches the route the licensed practitioner ordered. Also check that the medication you are using can be administered by the route ordered. For example, do not confuse ear (otic) drops with eye (optic) drops. Check that the patient can receive the drug by this route and that the route seems appropriate. For example, if the patient has an injury at the specified injection site, consult the licensed practitioner for a possible alternative site or a different route.

Right Time

Be sure to give the drug at the right time. If it must be given after meals, make sure the patient has eaten recently. For certain drugs, you must ensure that it is the correct time of day and the correct time in a series of doses. For example, timing is crucial with allergy shots because of possible reactions.

Right Documentation

Document the procedure immediately after administering the drug or vaccine to the patient. Do not wait until later and do not document before administration. Be sure to include the date, time, drug or vaccine name, lot number, dose, administration route, patient reaction, and patient education about the drug, as well as your first initial and last name. If the drug is a controlled substance, also document it on the controlled substance inventory record. Always double-check your entry for computer documentation before submitting. Use neat handwriting for written documentation.

Right Reason

The person who administers the medication should know the reason the medication is being given.

Right to Know

All patients have the right to be educated about the medications they are receiving. This should include the reason, the effect, and the side effects of medications.

Right to Refuse

Every patient has the right to refuse a medication. If a patient does refuse a medication or vaccine, you should report this to the physician who ordered the medication. A refusal of medication by a patient should be documented in the patient’s medical record.

Right Technique

Always use the proper administration technique. If you have not given a drug or vaccine by the ordered route recently, review the technique before administering the drug.

Drug Routes and Equipment LO 53.3

The physician may ask you to administer drugs by one of the routes outlined in Table 53-2. Most patients take a prescription to a pharmacy to be filled and then take oral drugs at home, so you may not need to administer these drugs in the office very often. However, you are likely to be asked to

- Place drugs in the patient’s mouth between the cheek and gum or under the tongue.
- Administer or teach a parent to administer a medication using a dropper, a medicine cup, an oral syringe, or a calibrated syringe. A **calibrated spoon** has markings (calibrations) that allow you to measure a dose. An oral syringe also has calibrations and a soft, flexible tip. See Figure 53-3.
- Administer a drug by any means other than by mouth (if permitted by your scope of practice and state laws). This would require the use of a syringe and safety-engineered needles, which are discussed later in the chapter.
- Demonstrate how to use an inhaler.
- Apply topical drugs (those applied to the skin).
- Administer or assist in administering drugs into the urethra, vagina, or rectum.
- Administer medications to the eye or ear, as discussed in the *Assisting with Eye and Ear Care* chapter.

These duties require you to master a variety of techniques to give drugs safely by any route.

TABLE 53-2 Routes and Methods of Drug Administration	
Route and Drug Forms	Method
Buccal route Tablets	Place drug between the patient’s gum and cheek. To ensure absorption, tell the patient to leave the tablet there until it dissolves and not to chew or swallow it. Tell the patient not to eat, drink, or smoke until the tablet is completely dissolved.
Inhalation therapy (nasal or oral) Aerosols Sprays Mists or steam	Administer the drug by inhalation to reach the respiratory tract. The drug will be absorbed in 7 to 20 seconds.
Intradermal route Solutions Powders for reconstitution	Administer the drug by injection between the upper layers of the patient’s skin.

(Continued)

TABLE 53-2 Routes and Methods of Drug Administration

Route and Drug Forms	Method
Intramuscular route Solutions Powders for reconstitution	Administer the drug by injection into the muscle. The drug will be absorbed in 3 to 5 minutes.
Intravenous route Solutions (often in bags of 250, 500, or 1,000 mL) Powders for reconstitution Blood and blood products	Administer the drug by injection or infusion into a vein. The drug will be absorbed in 15 to 30 seconds.
Ophthalmic (eye) or otic (ear) route Solutions Ointments	Apply the drug, usually as drops, in the patient's eye or ear.
Oral route Tablets Capsules Liquids Lozenges	Give the drug to the patient to swallow. The drug will be absorbed in 20 minutes to 3 hours, depending on food and drug ingestion.
Rectal route Suppositories Solutions	Insert a suppository into the patient's rectum. Administer a solution as an enema, using a tube and nozzle.
Subcutaneous route Solutions Powders for reconstitution	Administer the drug by injection into the subcutaneous layer of skin. The drug will be absorbed in 3 to 5 minutes.
Sublingual route Tablets Sprays	Place the drug under the patient's tongue. To ensure absorption, tell the patient to leave the tablet there until it dissolves and not to chew or swallow it. Tell the patient not to eat, drink, or smoke until the tablet is completely dissolved.
Topical route Ointments Lotions Creams Tinctures Powders Sprays Solutions	Apply the drug to the patient's skin or rub it into the skin.
Transdermal route Patches	Apply the drug to a clean, dry, nonhairy area of the patient's skin.
Urethral route Solutions	Administer the drug by instilling it in the patient's bladder, using a catheter.
Vaginal route Solutions Suppositories Ointments Foams Creams	Administer a solution as a douche, using a tube and nozzle. Administer other forms by inserting them into the vagina with an applicator.

► Medications by Mouth

LO 53.4

Medications that are put in the mouth are usually swallowed. This is called *oral administration*. Medications that are not meant to be swallowed also may be placed in the mouth. These methods include buccal and sublingual administration.

Oral Administration

Drugs that are swallowed are absorbed relatively slowly as they travel along the gastrointestinal (GI) tract. Drugs for oral administration include tablets, capsules, lozenges, and liquids. One special type of tablet you should be aware of is a **scored** tablet. See Figure 53-4. This medication can be broken into pieces along a scored (indented) line on the tablet.

Oral administration is contraindicated in patients who have severe nausea, are comatose, or cannot swallow. Certain drugs are ineffective when administered orally because the digestive process changes them chemically to an ineffective form or does not deliver them to the bloodstream quickly enough.

Many drugs, however, are most effective when given orally. These include antibiotics, vitamins, throat lozenges, and cough syrups. Although these drugs are familiar to most people, as a medical assistant, you must follow certain steps to ensure that the patient understands the drug and that the drug is administered safely and effectively. The steps for oral administration are outlined in Procedure 53-1 at the end of this chapter.

Buccal and Sublingual Administration

Although **buccal** and **sublingual** drugs are placed in the mouth, they do not continue along the GI tract. Instead, they dissolve and are absorbed in the buccal area (between the

cheek and gum) or the sublingual area (under the tongue), where they are placed. The medication is absorbed through tissue that is rich in capillaries and the drug enters the bloodstream directly. Because the drug does not pass into the stomach or intestines before absorption, it produces a therapeutic effect more quickly than do oral drugs.

Specially formulated tablets may be given by the buccal or sublingual routes. When you administer buccal or sublingual medications, your role usually includes teaching the patient how to administer these medications at home. See Procedure 53-2 at the end of this chapter.

FIGURE 53-4 Unscored tablets should never be broken. Scored tablets, like the ones shown here, can be broken only along the scored line.

► Medications by Injection

LO 53.5

Medications given by injection are called *parenteral medications*. Parenteral administration is the administration of a substance such as a drug by muscle, vein, or any means other than through the GI tract. Although the parenteral route offers the advantage of rapid drug action, it has several potential drawbacks. Parenteral administration poses more safety risks for the patient because, after the drug has been injected, it cannot be retrieved.

Parenteral administration also increases your risk of potential exposure to bloodborne pathogens when you perform injections and dispose of used needles. To minimize risks, follow standard precautions during injections. Also adhere to Occupational Safety and Health Administration (OSHA) and Environmental Protection Agency (EPA) regulations for disposing of contaminated needles and other sharp items. Offices must provide a rigid, puncture-proof container for collecting disposable sharp instruments. This container must be self-sealing and must have a lock-tight cap and a safety neck.

After using a needle, lancet, or syringe, engage the safety mechanism; then immediately place it in the sharps container. See Figure 53-5. To avoid puncturing yourself, always ensure that the safety mechanism is engaged and do not force the needle, lancet, or syringe into the container. If you do accidentally stick yourself, follow OSHA guidelines. Wash the area with soap and water, report the incident to your supervisor, and seek medical treatment.

Never let a sharps container become full. When the container is two-thirds full, seal it and follow your office procedure for container disposal. Before giving an injection, be aware of all injection safety practices, as discussed in the *Infection Control Practices* chapter.

Needles

When you administer a parenteral drug, you must select the appropriate needle, syringe, and drug form to use on the basis of the type of injection. The following are methods of injection:

- Intradermal (ID), or within (between) the upper layers of the skin
- Subcutaneous (subcut), or beneath the skin
- Intramuscular (IM), or within a muscle
- Intravenous (IV), or directly into a vein

See Figure 53-6.

Needles consist of a hub, hilt, shaft, lumen, point, and bevel (Figure 53-7). The hub of the needle fits onto the syringe. The needle tip is beveled (sloped at the opening). The bevel helps the needle cut through the skin with minimum trauma.

Needles are available in various gauges (inside diameters) and lengths (Figure 53-8). A needle's gauge is expressed

FIGURE 53-5 To prevent needlestick injuries, engage the safety mechanism and place all needles in a sharps container like this one immediately.

© McGraw-Hill Education

with numbers. The smaller the number, the larger the gauge. For example, a 25-gauge needle is smaller than an 18-gauge needle. Use the right gauge for the type of injection and the viscosity (thickness) of the drug to be administered.

When selecting a needle, consider its length. It must be long enough to penetrate the appropriate layers of tissue, but not so long as to go too deep. Choose the correct needle length on the basis of the type of injection as well as the patient's size, amount of fatty tissue, and injection site. Table 53-3 lists the approximate ranges of needle gauge and length that are typically used for intradermal, subcutaneous, and intramuscular injections. Always use the smallest allowable needle that will work for the patient, medication, and injection site. For example, you will rarely use an 18-gauge needle for an IM injection. One exception is if you are injecting viscous (thick) medication into a large muscle on a large patient.

Syringes

Syringes have two basic parts: a barrel and a plunger. The barrel is the calibrated cylinder that holds the drug. The plunger forces the drug through the barrel and out the needle. The syringe may be packaged with the needle attached and a guardcap over the needle, or the syringe and needle may be packaged separately. All syringes must include a needlestick prevention safety device. See Figure 53-9.

Syringes come in many sizes and are calibrated according to how the syringe will be used. For example, the common 3-mL syringe is divided into tenths of a milliliter. It is used to measure most drugs. A tuberculin (TB) syringe holds 1 mL and is calibrated in hundredths of a milliliter. Insulin syringes are calibrated in units (U), commonly either 50 U or 100 U (Figure 53-10). Unlike other syringes, insulin syringes have permanently attached needles and no dead space (fluid remaining in the needle or syringe after the plunger is depressed fully). These differences help the patient self-administer the correct amount of insulin.

Forms of Packaging for Parenteral Drugs

Parenteral drugs are supplied in the forms shown in Figure 53-11. They include cartridges, ampules, and vials.

FIGURE 53-6 Injection needles are placed into separate areas under the skin: (a) intradermal (ID), (b) intramuscular (IM), (c) subcutaneous (subcut), or (d) intravenous (IV).

(a)

FIGURE 53-7 Understanding the parts of a needle will help you use it correctly.

- A cartridge is a small barrel prefilled with a sterile drug. It slips into a reusable syringe assembly.
- An ampule is a small glass or plastic container that is sealed to keep its contents sterile. It must be opened and used with care, as described in Procedure 53-3 at the end of this chapter.
- A vial is a small bottle with a rubber diaphragm that can be punctured by needle. A vial contains a liquid or powder, which must first be reconstituted with a **diluent** (liquid used to dissolve and dilute a drug), as described in Procedure 53-4 at the end of this chapter. It may contain a single or multiple doses. This procedure requires two needles and syringe sets—one for inserting the diluent into the vial and another to draw and administer the reconstituted drug—to avoid using a contaminated needle. The first needle is considered contaminated when you set it down to mix the diluent and the drug.

(b)

FIGURE 53-8 (a) The gauge of the needle relates to the diameter. The larger the number, the smaller the needle diameter. (b) Always choose a needle with a length and gauge appropriate to the type of injection, the drug being injected, and the patient receiving the injection.

Go to CONNECT to see video exercises about Drawing a Drug from an Ampule and Reconstituting and Drawing a Drug for Injection.

TABLE 53-3 Suggested Needle Gauge, Length, Injection Amount, and Location

Type	Age	Needle Size	Needle Length	Maximum Injection Amount	Location
Intradermal (ID)					
ID	All ages	25 to 26 gauge	$\frac{3}{8}$ to $\frac{1}{2}$ inch	0.1 mL	Interior aspect of forearm (most common)
Subcutaneous (Subcut)					
Subcut	1 to 12 months	23 to 27 gauge	$\frac{5}{8}$ inch	1 mL	Fatty tissue over anterior lateral thigh muscle
Subcut	> 12 months to adult	23 to 27 gauge	$\frac{1}{2}$ to $\frac{3}{4}$ inch; $\frac{5}{8}$ is most common	1 mL	Fatty tissue over anterior lateral thigh muscle or over triceps
Intramuscular (IM)					
IM	1 to 28 days	18 to 23 gauge	$\frac{5}{8}$ inch	1 mL	Anterolateral thigh muscle
IM	1 to 12 months	18 to 23 gauge	1 inch	1 mL	Anterolateral thigh muscle
IM	1 to 2 years	18 to 23 gauge	1 to $1\frac{1}{4}$ inch; $\frac{5}{8}$ to 1 inch	1 mL	Anterolateral thigh muscle Deltoid muscle of arm
IM	3 to 18 years	18 to 23 gauge	$\frac{5}{8}$ to 1 inch; 1 to $1\frac{1}{4}$ inch	2 mL	Deltoid muscle of arm Anterolateral thigh muscle
IM	All adults $\geq$ 19 years < 130 lb	18 to 23 gauge	$\frac{5}{8}$ to 1 inch	3 mL	Deltoid muscle of arm
IM	All adults $\geq$ 19 years Female 130 to 200 lb Male 130 to 260 lb	18 to 23 gauge	1 to $1\frac{1}{2}$ inch	3 mL	Deltoid muscle of arm
IM	Male adults $\geq$ 19 years Female 200 + lb Male 260 + lb	18 to 23 gauge	$1\frac{1}{2}$ inch	3 mL	Deltoid muscle of arm

FIGURE 53-9 The parts of a standard syringe include (a) the needle; (b) the syringe hub; (c) the barrel that contains the liquid; (d) the plunger; (e) the trailing ring; (f) the plunger tip, also called the leading ring; and (g) the needlestick prevention safety device.

Methods of Injection

Injections are the most common method of drug administration in a medical office. You need to be knowledgeable about all injection methods: intradermal, subcutaneous, intramuscular, and intravenous.

Intradermal An **intradermal (ID)** injection is administered between the upper layers of skin at an angle almost parallel to the skin, as described in Procedure 53-5 at the end of this chapter. Common sites for intradermal injections are

the forearm and back. Intradermal injections are usually used to administer a skin test, such as an allergy test or a TB test. When choosing an injection site on patients, avoid scarred, blemished, or hairy areas because those features interfere with your ability to interpret test results on the skin.

The drug is injected under the top skin layer and a little bubble, or wheal, is raised. If the body reacts to the drug, erythema (redness) and induration (hardening) occur. This reaction generally takes place 15 to 20 minutes after an allergy test and from 48 to 72 hours after a TB test.

FIGURE 53-10 Always check the calibrations of insulin syringes carefully because the marks on syringes of different sizes use different scales.

Subcutaneous A **subcutaneous (subcut)** injection provides a slow, sustained release of a drug and a relatively long duration of action. Generally, 1 mL or less of a drug can be delivered by a subcut injection (see Procedure 53-6 at the end of this chapter). Various drugs, such as insulin and heparin, are commonly administered by a subcut injection. Common subcutaneous injection sites include an area on the back between the shoulder blades, the outer sides of the upper arms and thighs, and the abdomen (except for a 2-inch area around the umbilicus).

To prepare for a subcut injection, select a site away from bones and blood vessels. Do not use an area that is edematous (swollen), scarred, or hardened or one that has a large amount of fat because these areas may not have the capillary network needed for absorption. When patients need regular subcut injections, remember to rotate injection sites systematically. Begin the rotation pattern by giving injections in rows in the same area of the body (such as the abdomen). After all those sites have been used once, proceed to the next area on the body (such as the right leg) and follow a similar pattern there. Rotating sites promotes drug absorption and prevents hard subcutaneous lumps from forming. At the injection site, ensure that you can pinch at least a 1-inch skinfold for the injection. If a patient is frail, dehydrated, or thin, you may need to use a site other than the back or abdomen to provide the necessary fold of skin.

FIGURE 53-11 Injectable drugs come in a cartridge (left), an ampule (center), or a vial (right).

© Cliff Moore

Intramuscular When a patient requires rapid drug absorption, you may be asked to administer an **intramuscular (IM)** injection, as described in Procedure 53-7 at the end of this chapter. An IM injection usually irritates a patient's tissues less than a subcut injection and allows administration of a larger amount of drug.

Common IM injection sites include the ventrogluteal, vastus lateralis, and deltoid muscles, illustrated in Figure 53-12. The dorsogluteal is used less because of the chance of hitting the sciatic nerve. Before giving an IM injection, identify the site carefully to prevent injury to blood vessels and nerves in the area. As with subcut injections, rotate sites if the patient must receive regular or multiple IM injections.

Take into consideration the patient's layer of fat when choosing an IM injection site. You want the injection to penetrate beyond the fat layer to muscle. If, for example, a patient is heavy in the buttocks and thighs, the deltoid may be the best site for administering an IM injection.

When injecting an IM drug that can irritate subcutaneous tissues, such as iron dextran (Imferon), use the **Z-track method**, illustrated in Figure 53-13. To do this, pull the skin and subcutaneous tissue to the side before inserting the needle at the site. After the drug is injected, release the tissue. This technique creates a zigzag path in the tissue layers, which prevents the drug from leaking into the subcutaneous tissue and causing irritation.

Intravenous Although **intravenous (IV)** injections are not commonly performed in a medical office or by medical

FIGURE 53-12 For intramuscular injection in an adult, use (a) the ventrogluteal site, (b) the deltoid site, or (c) the vastus lateralis site.

assistants, certain drugs may be administered this way. Drugs also may be mixed and dissolved into a **solution** (a homogeneous mixture of a solid, liquid, or gaseous substance in a liquid) and given by IV **infusion** (slow drip) into a vein. Examples of IV drugs include powerful antibiotics, chemotherapeutic drugs, emergency drugs, and electrolytes. Because these drugs are introduced directly into the bloodstream, they produce an almost immediate effect. They also can cause sudden adverse reactions.

Although in most cases a licensed practitioner must administer an IV drug, you may assist by laying out supplies and equipment. When assisting with any intravenous medications, gather the ordered drug and a tourniquet, bedsaver pad, gloves, iodine and alcohol swabs, venipuncture device, tape, and gauze pad, as ordered. Obtain other supplies and equipment depending on the specific type of infusion or injection being administered.

FIGURE 53-13 Use the Z-track method for IM injection of irritating solutions. (a) Pull the skin to one side before inserting the needle. (b) After injecting the drug, release the skin to seal off the needle track.

► Other Medication Routes

LO 53.6

Additional parenteral routes of administration include inhalation therapy (sometimes called respiratory therapy); topical application; and urethral, vaginal, and rectal administration.

Inhalation Therapies

Inhalation therapy is medication that is delivered into the respiratory system during inhalation. This medication can be administered through the mouth or nose. There are a number of disorders for which the physician may order an inhaler or aerosol form of medication. For example, an oral inhaler is frequently used by patients with asthma, whereas a nasal inhaler is frequently used for local treatment of nasal congestion. Nasal inhalers also are used to administer medicines for systemic effect, such as a vasopressin derivative for nocturnal bedwetting. Some types of influenza vaccines are now delivered by nasal inhalation. Always read the inserts for inhaled drugs for a detailed description of the exact procedure for the type of inhalation you will be administering. Procedure 53-8, at the end of this chapter, provides the basic steps of the procedure, as well as needed patient education.

Topical Application

Topical application is the direct application of a drug on the skin. Topical drugs can take the form of creams, lotions, **ointments** (salves), tinctures, powders, sprays, and solutions, which are used for their local effects. They include antibacterial and antifungal drugs, as well as corticosteroids.

To apply a cream, lotion, or ointment, use long, even strokes with a cotton-tipped applicator and/or a gloved finger when rubbing it into the skin. Follow the direction of the hair growth to avoid irritating the hair follicles and skin. To apply a powder, shake it on but do not rub it in.

A specialized type of topical administration that produces a systemic effect is the **transdermal** system (or patch). See Figure 53-14. A drug administered through the transdermal patch is absorbed through the skin directly into the bloodstream. The patch slowly and evenly releases a systemic drug, such as scopolamine, nitroglycerin, estrogen, or fentanyl, through the skin. The patient receives a timed-release dose, usually over a day or several days. See Procedure 53-9 at the end of this chapter.

Urethral Administration

The urethral route is used when antibiotic and antifungal drugs are needed locally—that is, at the site of infection—for some urinary tract infections. Depending on the nature of the infection and the duration of drug action, the physician or a nurse may instill liquid drugs only one time or several times a day for a week. Urethral administration is used in both men and women.

Urethral drug administration requires passing a small-diameter urinary catheter into the bladder, instilling a drug through it, and clamping the catheter to let the drug bathe the urinary bladder walls. See Procedure 53-10 at the end of this chapter.

FIGURE 53-14 A transdermal patch should include the date, time, and initials added to the patch when applied by a medical assistant.

© Total Care Programming, Inc.

Vaginal Administration

Physicians usually prescribe vaginal drugs to treat local fungal infections. The drugs also may be used for local bacterial infections. They are usually packaged as suppositories (the most common form), solutions, creams, ointments, and foams. The liquid form of vaginal medication is administered by performing a **douche** (vaginal irrigation). This process is similar to giving a urethral drug, but it requires a special irrigating nozzle. Patients frequently ask about administering vaginal medications, and they usually administer such medications at home. Therefore, you must be prepared to provide detailed patient education for this route of administration. The physician may ask you to administer the first dose as a means of teaching a patient the method to use at home, or you may be asked to administer a one-time-only dose. See Procedure 53-11 at the end of this chapter.

Rectal Administration

Certain medications, such as drugs used to treat constipation, nausea, and vomiting, may be administered by the rectal route. These medications may be given in the form of suppositories or enemas and may produce local or systemic effects. See Procedure 53-12 at the end of this chapter.

► Special Considerations

LO 53.7

Pediatric, pregnant, breast-feeding, and geriatric patients require special considerations when administering medications. When giving a drug to these patients, you must adjust patient care and technique as needed. Note: Geriatric considerations are discussed in the *Assisting in Geriatrics* chapter.

Pediatric Patients

Children pose special challenges in drug administration and use. Their physiology and immature body systems may make drug effects less predictable because drugs are absorbed, distributed, metabolized, and excreted differently in children than in adults. Therefore, plan to observe a pediatric patient closely for adverse effects and interactions.

- Distract the patient. Talk to the child while giving the injection. Don't ask permission. Often the injection is performed and over before the child realizes it.

- Use an anesthetic topical agent prior to the injection. This can be applied in the office or at home before the patient arrives in the office.
- Try not to allow the child to see the syringe before giving the injection.
- Be swift. Do not allow a lot of time to pass before giving the injection—the faster the better.
- Praise the child. Say things that promote maturity and self-esteem.

In many cases, pediatric patients require more than one vaccine injection in a single limb (vastus lateralis). When this is the case, the injections should be at least 1 inch apart on the site, and the specific location of each vaccine should be documented.

Restraining Methods Sometimes a pediatric patient will need to be restrained in order for you to administer an injection. Two medical assistants may be needed to safely restrain a child while giving an injection. Common restraining methods include the following:

- Have the child “hug the mother.” The mother holds the child in front of her, with the child’s thighs extended on either side of her torso. As the mother is talking to her child, make the injection in the vastus lateralis.
- Weight-bearing restraining is better than muscular control. Have the child sit on the edge of the examining table and use your weight to immobilize the child’s legs against the table.

Pregnant Patients

When dealing with pregnant patients, remember that you are caring for two patients at once: the mother and her fetus. When you give the mother a drug, you also may be giving it to the fetus. Some drugs can cause physical defects in the fetus if the mother takes them during pregnancy (especially in the first trimester). It is extremely important to double-check the drug in a credible drug reference for toxicology or pregnancy warnings. After administering the drug, assess the patient carefully for therapeutic and adverse effects of the drug. If the physician orders a drug for a pregnant patient, double-check the order against the pregnancy drug risk categories discussed in the *Principles of Pharmacology* chapter. If it is a high-risk drug, check with the physician before administering the drug.

Patients Who Are Breast-Feeding

Some drugs are excreted in breast milk and can thus be ingested by a breast-feeding infant. This ingestion can be dangerous because infants have immature body systems and cannot metabolize and excrete drugs that are safe for the mother. Some drugs, such as sedatives, diuretics, and hormones, can reduce the mother’s flow of breast milk.

Whenever a drug is ordered for a patient who is breast-feeding, check a drug reference to see whether the drug is contraindicated during lactation. If so, consult the licensed practitioner. If not, teach the mother to recognize signs of adverse drug effects in her infant. If a mother must take a drug that affects lactation, advise her to supplement breast-feedings with infant formula.

► Patient Education About Medications

LO 53.8

As a medical assistant, you have an important role in patient instruction about medications. This role may vary depending on your state, training, or place of employment, but the importance of drug education should not be underestimated. Specific instructions should be given about all the drugs a patient is taking, whether prescription or over-the-counter (OTC). Patients also should know how to take and record their medications safely and correctly.

Over-the-Counter Drugs

Even though patients can obtain OTC drugs without a prescription, they need to know several important facts to use them safely. Patients should not treat themselves with OTC drugs as a way to avoid medical care. For example, OTC drugs are available to treat recurrent yeast infections. Nonetheless, a patient should consult a licensed practitioner the first time she develops an infection.

Patients also should know that OTC drugs may not produce enough therapeutic benefit in some cases or be dangerous when used in combination with other substances. For example, a combination of the OTC medication acetaminophen (Tylenol®) and alcohol can cause liver damage. In addition, some OTC drugs may even mask symptoms or aggravate a problem.

Many OTC drugs contain more than one active ingredient. These extra ingredients, such as aspirin, acetaminophen, or caffeine, can cause allergic reactions or other undesirable effects. Excess caffeine can cause elevated heart rates. Too much acetaminophen (Tylenol®)—over 4 grams in 24 hours—can inadvertently be taken, causing severe liver damage.

Prescription Drugs

Before patients begin drug therapy, they should be informed of certain considerations (such as when and how to take the drug) and drug safety precautions. First you must check a credible drug information resource about any drug with which you are not familiar.

As part of your patient education, provide instructions orally and, if possible, in writing. For commonly prescribed medications, you can obtain preprinted information sheets or create one using an electronic health record (EHR) program. Most pharmacies now routinely provide these with each dispensed drug. See Figure 53-16.

An important aspect of this kind of information is teaching the patient how to read a prescription drug label. Instruct the patient to be particularly alert for special instructions and warning labels, such as those shown in Figure 53-17.

Interactions

Interactions may occur between two prescription or nonprescription drugs or between a drug and food and may cause serious effects. The greater the number of drugs the patient takes, including over-the-counter medications or supplements, the greater the chance of a drug interaction.

Drug-Drug Interactions When two drugs are taken at the same time, there are several possible interactions. In some cases, the effects of both drugs are increased, causing either a toxic or beneficial effect. For example, when alcohol is combined with diazepam (Valium®), there is a potential toxic effect of severe central nervous system depression because one drug intensifies the effect of the other. An example of a beneficial effect is the combination of acetaminophen and codeine, which increases the activity of both drugs, allowing the physician to prescribe a lower dose of each. In fact, this combination of drugs is available in one tablet (Tylenol® with codeine).

In other cases, the effects of both drugs are decreased, or one drug cancels out the effect of the other. For example,

BWV Medical Associates, PC
305 Main Street
Port Snead, YZ 12345-9876

Patient Name: Mohammad Nassar

RX#: 711428172

Drug: Albuterol Inhalation Aerosol

COMMON USES:

To treat asthma, bronchitis, and other lung diseases.

HOW SHOULD I USE IT?

Follow your doctor's and/or the package instructions. Shake well before each use. Rinse mouth after each inhalation to avoid dryness. If breathing has not improved in 20 minutes, call the doctor.

ARE THERE ANY SIDE EFFECTS?

Very unlikely, but report: Flushing, trembling, headache, nausea, vomiting, rapid heartbeat, chest pain, weakness, dizziness.

HOW DO I STORE THIS?

Store at room temperature away from moisture and sunlight. Do not puncture. Do not store in the bathroom. Rinse and clean inhaler regularly as described in package instructions.

FIGURE 53-17 Teach the patient to heed warning labels and instructions on drug bottles.

© Cliff Moore

FIGURE 53-16 Drug information sheets, like this one, are important for consumers to understand the medications they are taking.

combining propranolol (Inderal®) with albuterol (Proventil®) causes each drug to lose its effectiveness.

In still other cases, the effect of one of the drugs is increased by the other. For example, the effect of digoxin (Lanoxin®) is increased by the presence of furosemide (Lasix®), but the furosemide still works at the same degree of effectiveness as when administered alone.

Drug interactions can lead to adverse reactions. For example, a patient who takes the prescription blood modifier (anticoagulant) warfarin (Coumadin®) to prevent blood clots must avoid taking aspirin for pain relief. Taking these drugs together increases the risk of uncontrolled bleeding.

To help prevent unintentional drug interactions, thoroughly check the patient's medication use. Be sure to ask about medications prescribed by specialists as well as OTC drugs and supplements. Question the patient about past and present use of alcohol and recreational drugs as well as herbal remedies. Update the chart as needed. If you detect a potential for drug interactions, notify the physician. Drug interaction checkers are available online.

Also teach patients about possible drug interactions and how to avoid or minimize them. For example, patients may need to take certain drugs at least 4 hours apart. As an example, the hormone replacement drug Synthroid® and calcium should not be taken together. Instruct patients to call the office if they think their drugs are interacting adversely.

Drug-Food Interactions Interactions between a drug and food can alter a drug's therapeutic effect. For example, taking tetracycline with milk can reduce the drug's effectiveness because of decreased absorption from the GI tract. The drug-food interaction between a monoamine oxidase (MAO) inhibitor (such as Parnate®, an antidepressant drug) and aged cheese or meat or other foods containing high levels of tyramine can produce a toxic effect. This interaction can cause a dangerous hypertensive crisis in which the patient's blood pressure rises quickly to dangerous levels, possibly leading to stroke and death.

A food that may interact with drugs is grapefruit and grapefruit juice. Interactions with some heart or blood pressure medications, such as nifedipine, might cause irregularities in heartbeat, called dysrhythmia.

Some drug-food interactions can affect the body's use of nutrients. For example, the cholesterol-lowering drugs cholesterolamine resin (Locholest®) and colestipol HCl (Colestid®)

may reduce the body's absorption of fat-soluble vitamins (A, D, E, and K) from food.

When teaching a patient about drug-food interactions, specify exactly which foods to avoid and when. For example, a patient may drink milk or eat food several hours before or after taking tetracycline, whereas a patient taking an MAO inhibitor must avoid foods that contain high levels of tyramine at all times. Explain what to expect if an interaction occurs, and describe how to deal with it.

Adverse Reactions

Reported adverse reactions associated with a drug are somewhat predictable and range from mild side effects, such as stomach upset, to severe or life-threatening allergic responses. For example, certain cholesterol-lowering medications, called statins (e.g., Lipitor®), can increase the likelihood of painful muscle disorders. Unpredictable adverse effects also can occur; they are unique to each patient.

Elderly patients and patients with liver or kidney disease are more susceptible than others to adverse reactions, because these conditions affect drug metabolism and excretion. When drugs are not metabolized properly or excreted from the body quickly enough, drugs can reach toxic levels, even with normal doses.

To help prevent adverse reactions, teach the patient to take the drug at the right time, in the right amount, and under the right circumstances. For example, the patient may need to take a cephalosporin with food to avoid nausea and diarrhea. Also teach the patient to recognize significant adverse effects and to call the office if any of them occur. The patient also should report any change in overall health because that change could be drug-related.

Tell patients to inform each of their doctors of any adverse reactions (including allergic reactions) they have had to drugs. Previous adverse reactions may prompt a doctor to adjust a dosage or select a different drug. A history of drug allergies may contraindicate the use of a particular drug.

Complete Medication List

Patients must inform the doctor of all substances they use regularly or periodically. This includes prescription and OTC drugs, plus herbals and supplements. It also includes past and present use of alcohol and recreational drugs. When patients have more than one doctor, tell them to inform each doctor about all medications they are taking. Encourage them to keep up-to-date medication lists with dosages (some patients keep this information on their home computers). This information can help patients and healthcare professionals prevent and monitor for drug interactions. The list should be kept on the patient chart and updated with every visit to the physician's office.

Patient Compliance

To help ensure that patients comply with instructions, confirm that they completely understand the name, dosage, and purpose of each drug prescribed for them. If patients must take more than one drug at a time, be sure they know the correct and relevant information for each one. In addition, cover each of the following points when educating patients about drugs:

- Explain how and when to take each drug to ensure its safety and effectiveness. Some drugs should be taken with food to minimize gastrointestinal irritation. Others should be taken on an empty stomach for proper absorption and metabolism. Some drugs must be taken once a day in the morning; others should be taken three or four times a day. If patients' medication schedules are complex, suggest that they create an alarm, chart, calendar, or diary to remind them of what drug to take and when, or create a schedule for them.
- Tell patients how long to take each drug. In the case of antibiotics, advise them to take the entire course of the drug as scheduled, even if they feel better before finishing it. In the case of medicines prescribed for chronic disease, advise patients that they will need to continue taking the medication unless the doctor tells them to stop. Be aware that some drugs, such as prednisone, must be tapered off slowly to prevent adverse reactions.
- Explain how to identify possible adverse reactions of each drug and safety measures related to adverse reactions. For example, instruct patients to avoid certain activities, such as driving or operating machinery, while taking a drug that causes drowsiness. If appropriate, inform patients that misuse of the drug may lead to dependence, and mention the dangers of drug dependence.
- Tell patients not to save medications that are over 1 year old or share them with anyone else. Old medications and those taken by people other than the patient for whom they were prescribed can cause severe, unexpected adverse effects. Advise patients to check the expiration date on all drugs and to discard them by wrapping in a tightly sealed container and placing in the trash. Flushing is not recommended due to possible water contamination. Some pharmacies will dispose of medications for patients.
- Suggest that patients avoid alcohol when taking certain drugs. Alcohol interacts with some drugs, causing adverse reactions such as lethargy, confusion, or coma.
- Tell patients to ask their pharmacists where to store each medication. Some drugs must be refrigerated. Others should be kept in a dry, cool area. Drugs should not usually be kept in a hot, damp place, such as a bathroom. They must always be kept out of the reach of children.
- Tell patients to take their drugs in a well-lit area so that they can read each drug label carefully before taking each dose. They should never assume that they are taking the right medication without reading the label on the container. If patients have poor vision, print the name of the drug and the dosage schedule clearly on a separate piece of paper or card to attach to the medication container.
- Instruct patients to call the licensed practitioner if they have any questions about their drug therapy.

▶ Charting Medications

LO 53.9

Whenever a patient receives some form of treatment, such as medication, a record is kept of that treatment. Special problems or circumstances are also recorded, such as new

symptoms, the patient's own statements, and how the patient tolerated the medications or treatment. Most charting in the physician's office is documented on a progress note or a medication administration record (MAR). These documents are essential to serve as communication tools for all health-care members who are connected to that patient. The medical record is considered a legal document and is taken as proof that medication or treatment was administered to the patient.

All chart entries must be factual, accurate, complete, current, organized, and confidential. Avoid using words or statements that can be interpreted as your opinion. For example, if a patient gags and spits up cough syrup you have just administered, you would not write that the patient did not like the taste of the medication; you would simply state "patient experienced difficulty in swallowing medication and expelled medication." Avoid terms such as *appear* and *seems*, which can lead you to draw assumptions without objective data to support them. Be specific. Chart what the patient said or did, not what you think. Use abbreviations when appropriate because they allow you to say a great deal in a small space.

Below you can see an EHR medicine charting example or progress note for Valarie Ramirez.

BWW **PROGRESS NOTE**

Patient Name: Valarie Ramirez

0900, PPD, 0.1 mL given ID, Rt. Forearm, Lot #222-01, Exp. Date 12/19, ABC Pharmaceutical Co., Pt to return to office in 48–72 hours for screening results. Pt tolerated well.

Date: 11/29/XX

Author: Kaylyn Haddix

Done

Close

Review your office's medical records to keep consistent with the charting methods used in them. Follow these simple rules:

- Before you begin, make sure you have the right chart and the right location in the chart.
- Chart medications directly from the physician order.
- Be specific. Do not write "Gave Demerol for pain in the evening." Instead, write, "(Date/Time), Demerol 100 mg given IM in right upper outer quadrant of gluteus maximus for c/o sharp pain, rated 7 on a scale of 10, in left arm, lot number, expiration date, initials."
- If using paper charts, do not leave gaps or skip lines. If an entry does not fill a complete line, draw a straight line to fill the gap. Put your signature or first initial and last name and title at the right side directly after the note.
- If you make an error, do not erase it. Draw a line through the mistake. The mistake should still be visible, so do not black it out. Initial it and then rechart the information correctly. Follow the specific procedure for making corrections in an electronic health record.
- Never use ditto marks.
- Write neatly in longhand or carefully enter into the electronic chart and check your note before submitting it. Ensure that your spelling is accurate.
- Use abbreviations and correct symbols. Most facilities have an approved abbreviation list to use as a reference.
- If you are unsure about charting, check with your supervising licensed practitioner.

PROCEDURE 53-1 Administering Oral Drugs

WORK // DOC

Procedure Goal: To safely administer an oral drug to a patient

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Patient chart/progress note, drug order (in patient chart), container of oral drug, small paper cup (for tablets, capsules, or caplets) or plastic calibrated medicine cup (for liquids), glass of water or juice, straw (optional), package insert or drug information sheet

Method:

1. Identify the patient and wash your hands.
2. Select the ordered drug (tablet, capsule, or liquid).
3. Check the rights, comparing information against the drug order.
RATIONALE: To ensure necessary accuracy.
4. If you are unfamiliar with the drug, check a drug reference, read the package insert, or speak with the physician. Determine whether the drug may be taken with or followed by water or juice.

5. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.

RATIONALE: To prevent a reaction to the medication.

6. Perform any calculations needed to provide the prescribed dose. If you are unsure of your calculations, check them with a coworker or the licensed practitioner.

Giving Tablets or Capsules

7. Open the container and tap the correct number into the cap. Do not touch the inside of the cap because it is sterile. If you pour out too many tablets or capsules and you have not touched them, tap the excess back into the container.

FIGURE Procedure 53-1 Step 7 Tap tablets gently into the cap.

© McGraw-Hill Education

8. Tap the tablets or capsules from the cap into the paper cup.

FIGURE Procedure 53-1 Step 8 Tap tablets from the cap into the paper cup.

© McGraw-Hill Education

9. Recap the container immediately.

RATIONALE: Recapping immediately protects the medication from exposure to air, which can break down the medication.

10. Give the patient the cup along with a glass of water or juice. If the patient finds it easier to drink with a straw, unwrap the straw and place it in the fluid. If patients have difficulty swallowing pills, have them drink some water or juice before putting the pills in the mouth.

RATIONALE: Additional fluid makes the pills float in the mouth and allows patients to swallow more easily.

Giving a Liquid Drug

11. If the liquid is a suspension, shake it well.

FIGURE Procedure 53-1 Step 11 Looking at eye level, find the base of the meniscus, which is the crescent-shaped form at the top of the liquid, for the correct measure.

12. Locate the mark on the medicine cup for the prescribed dose. Keeping your thumbnail on the mark, hold the cup at eye level and pour the correct amount of the drug. Keep the label side of the bottle on top as you pour or put your palm over it.

RATIONALE: To prevent liquid drips from obscuring the label.

13. After pouring the drug, place the cup on a flat surface and check the drug level again. At eye level, the base of the meniscus (the crescent-shaped form at the top of the liquid) should align with the mark that indicates the prescribed dose. If you poured out too much, discard it.

RATIONALE: Do not return it to the container because medicine cups are not sterile.

14. Give the medicine cup to the patient with instructions to drink the liquid. If indicated, offer a glass of water or juice to wash down the drug.

After You Have Given an Oral Drug

15. Wash your hands.
16. Give the patient an information sheet about the drug. Discuss the information with the patient and answer any questions. If the patient has questions you cannot answer, refer her to the licensed practitioner.
17. Document the drug administration in the patient's chart with date, time, drug name, dosage, expiration date, lot number, manufacturer, route, site, significant patient reactions, and any patient education.

PROCEDURE 53-2 Administering Buccal or Sublingual Drugs

WORK // DOC

Procedure Goal: To safely administer a buccal or sublingual drug to a patient

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Patient chart/progress note, drug order (in patient chart), container of buccal or sublingual drug, small paper cup, package insert or drug information sheet

Method:

1. Identify the patient and wash your hands.
2. Select the ordered drug.
3. Check the rights, comparing information against the drug order.

RATIONALE: To ensure necessary accuracy.

4. If you are unfamiliar with the drug, check the PDR or other credible drug reference, read the package insert, or speak with the licensed practitioner.
5. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.

RATIONALE: To prevent a reaction to the medication.

6. Perform any calculations needed to provide the prescribed dose. If you are unsure of your calculations, check them with a coworker or the licensed practitioner.
7. Open the container and tap the correct number into the cap. Do not touch the inside of the cap because it is sterile. If you pour out too many tablets or capsules and you have not touched them, tap the excess back into the container.
8. Tap the tablets or capsules from the cap into the paper cup.
9. Recap the container immediately.

RATIONALE: Recapping immediately protects the medication from exposure to air, which can break down the medication.

Giving Buccal Medication

10. For a buccal drug, provide patient instruction, including
 - Do not chew or swallow the tablet.
 - Place the medication between the cheek and gum until it dissolves.

RATIONALE: This area is rich in blood supply to promote rapid absorption of the drug.

- Do not eat, drink, or smoke until the tablet is completely dissolved.

RATIONALE: Food and fluids wash the drug into the gastrointestinal (GI) tract, slowing absorption or allowing gastric juices to destroy it. Smoking increases salivation, causing impaired absorption of the drug.

Giving a Sublingual Drug

11. For a sublingual drug, provide patient instruction, including
 - Do not chew or swallow the tablet.

FIGURE Procedure 53-2 Step 10 Place a buccal drug between the cheek and gum.

- Place the medication under the tongue until it dissolves.

RATIONALE: The capillaries in this area promote rapid absorption of the drug.

- Do not eat, drink, or smoke until the tablet is completely dissolved.

RATIONALE: Food and fluids wash the drug into the GI tract, slowing absorption or allowing gastric juices to destroy it. Smoking increases salivation, causing impaired absorption of the drug.

FIGURE Procedure 53-2 Step 11 Place a sublingual drug under the tongue.

After You Have Given a Buccal or Sublingual Medication

12. Remain with the patient until the tablet dissolves to monitor for possible adverse reactions and to ensure that the patient has allowed the tablet to dissolve in the mouth instead of chewing or swallowing it.
13. Wash your hands.
14. Give the patient an information sheet about the drug. Discuss the information with the patient and answer

any questions. If the patient has questions you cannot answer, refer her to the licensed practitioner.

15. Document the drug administration in the patient's chart with date, time, drug name, dosage, expiration date, lot number, manufacturer, route, site, significant patient reactions, and any patient education.

PROCEDURE 53-3 Drawing a Drug from an Ampule

Procedure Goal: To safely open an ampule and draw a drug, using sterile technique

OSHA Guidelines:

Materials:

Ampule of drug, alcohol swab, 2 × 2 gauze square, small file (provided by the drug manufacturer), sterile filtered needle, sterile needle, and a syringe of the appropriate size

Method:

1. Wash your hands and put on exam gloves.
2. Gently tap the top of the ampule with your forefinger to settle the liquid to the bottom of the ampule.
3. Wipe the ampule's neck with an alcohol swab.
4. Wrap the 2 × 2 gauze square around the ampule's neck; then snap the neck away from you. If it does not snap easily, score the neck with the small file and snap it again.

FIGURE Procedure 53-3 Step 4 To prevent possible injury, wrap the neck of the ampule with gauze before snapping.

© McGraw-Hill Education

5. Insert the filtered needle into the ampule without touching the side of the ampule.

RATIONALE: A filtered needle will prevent contamination of the medication.

6. Pull back on the plunger to aspirate (remove by vacuum or suction) the liquid completely into the syringe.
7. Replace with the regular needle and push the plunger on the syringe until the medication just reaches the tip of the needle. The drug is now ready for injection.

PROCEDURE 53-4 Reconstituting and Drawing a Drug for Injection

Procedure Goal: To reconstitute and draw a drug for injection, using sterile technique

OSHA Guidelines:

Materials: Vial of drug, vial of diluent, alcohol swabs, two disposable sterile needle and syringe sets of appropriate size, sharps container

Method:

1. Wash your hands and put on exam gloves.

2. Place the drug vial and diluent vial on the countertop. Wipe each rubber diaphragm with a fresh alcohol swab.
3. Loosen the cap from the needle and the guard from the syringe. Pull the plunger back to the mark that equals the amount of diluent needed to reconstitute the drug ordered.

RATIONALE: This action aspirates air into the syringe.

4. Puncture the diaphragm of the vial of diluent with the needle and inject the air into the diluent.

RATIONALE: This action creates positive pressure that lets you draw the diluent easily. If you do not add air, a vacuum forms, making it difficult to draw the diluent.

FIGURE Procedure 53-4 Step 4 Injecting air into the diluent.

© McGraw-Hill Education

5. Invert the vial and aspirate the diluent.
6. Remove the needle from the diluent vial, inject the diluent into the drug vial, and withdraw the needle. Properly dispose of this needle and syringe.
7. Roll the vial between your hands to mix the drug and diluent thoroughly. Do not shake the vial unless so directed on the drug label. When completely mixed, the solution in the vial should have no flakes. The

solution may be clear or cloudy when completely mixed (depending on the drug).

8. Remove the cap and guard from the second needle and syringe.
9. Pull back the plunger to the mark that reflects the amount of drug ordered. Inject the air into the drug vial.
10. Invert the vial and aspirate the proper amount of the drug into the syringe. The drug is now ready for injection.

FIGURE Procedure 53-4 Step 10 Aspirating the drug into the syringe.

© McGraw-Hill Education

PROCEDURE 53-5 Giving an Intradermal (ID) Injection

WORK // DOC

Procedure Goal: To administer an intradermal injection safely and effectively, using sterile technique

OSHA Guidelines:

Materials: Patient chart/progress note, drug order (in patient chart), alcohol swab, disposable needle and syringe of the appropriate size filled with the ordered dose of drug, sharps container

Method:

1. Identify the patient. Wash your hands and put on exam gloves.
2. Check the rights, comparing information against the drug order.

RATIONALE: To ensure necessary accuracy.

3. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.
4. Identify the injection site on the patient's forearm. To do so, rest the patient's arm on a table with the palm up. Measure two to three finger-widths below the antecubital space and a hand-width above the wrist. The space between is available for the injection.
5. Prepare the skin with the alcohol swab, moving in a circle from the center out.

FIGURE Procedure 53-5 Step 4 This space is available for intradermal injection sites.

6. Let the skin dry before giving the injection.
RATIONALE: To prevent you from introducing antiseptic under the skin, which could cause irritation and falsify intradermal test results.
7. Hold the patient's forearm and stretch the skin taut with one hand.
8. With the other hand, place the needle—bevel up—almost flat against the patient's skin. Press the needle against the skin and insert it.

FIGURE Procedure 53-5 Step 8 Inserting the needle for an intradermal injection.

© McGraw-Hill Education

FIGURE Procedure 53-5 Step 9 Medication collects under the skin, forming a wheal, during an intradermal injection.

9. Inject the drug slowly and gently. You should see the needle through the skin and feel resistance. As the drug enters the upper layer of skin, a wheal (raised area of the skin) will form.
10. After the full dose of the drug has been injected, withdraw the needle. Properly dispose of used materials and the needle and syringe immediately.
11. Remove the gloves and wash your hands.
12. Stay with the patient to monitor for unexpected reactions.
13. Document the injection in the patient's chart with date, time, drug name, dosage, expiration date, lot number, manufacturer, route, site, significant patient reactions, and any patient education.

PROCEDURE 53-6 Giving a Subcutaneous (Subcut) Injection

WORK // DOC

Procedure Goal: To administer a subcutaneous injection safely and effectively, using sterile technique

OSHA Guidelines:

Materials: Patient chart/progress note, drug order (in patient's chart), alcohol swabs, sterile 2 × 2 gauze or cotton ball, container of the ordered drug, disposable needle and syringe of the appropriate size, sharps container

Method:

1. Identify the patient. Wash your hands and put on exam gloves.
2. Check the rights, comparing information against the drug order.
RATIONALE: To ensure necessary accuracy.
3. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.
4. Prepare the drug and draw it up to the mark on the syringe that matches the ordered dose.
5. Choose a site and clean it with an alcohol swab, moving in a circle from the center out. Let the area dry.
6. Pinch the skin firmly to lift the subcutaneous tissue.

FIGURE Procedure 53-6 Step 5 Many sites are available for subcutaneous injection.

7. Position the needle—bevel up—at a 45- to 90-degree angle to the skin.
RATIONALE: The angle of the needle helps ensure that the medication is administered into the correct location. A 90-degree angle is used when you can pinch at least 2 inches. A 45-degree angle is used when you can only pinch 1 inch of skin.

(a)

(b)

FIGURE Procedure 53-6 Step 7 Positioning the needle for subcutaneous injection using your dominant hand: (a) 90-degree angle (right hand dominant); (b) 45-degree angle (left hand dominant).

© McGraw-Hill Education

8. Insert the needle in one quick motion using your dominant hand; then release the skin and inject the drug slowly. With some medications, you will check the placement of the needle by pulling back on the plunger before injecting. If blood is seen in the hub, you should withdraw the needle and start with a fresh needle and syringe. If no blood is seen, inject the medication slowly.
9. After the full dose of the drug has been injected, place a 2×2 gauze over the site and withdraw the needle at the same angle you inserted it. You can hold this gauze in your non-dominant hand as shown in Figure 53-6 Step 7(a).
10. Apply pressure at the puncture site with the gauze or cotton ball.
11. Massage the site gently to help distribute the drug, if indicated. Do not massage insulin, heparin, or other anticoagulant medications.
RATIONALE: *Massaging a site for heparin can cause bruising.*
12. Properly dispose of the used materials and the needle and syringe.
13. Remove the gloves and wash your hands.
14. Stay with the patient to monitor for unexpected reactions.
15. Document the injection in the patient's chart with date, time, drug name, dosage, expiration date, lot number, manufacturer, route, site, significant patient reactions, and any patient education.

PROCEDURE 53-7 Giving an Intramuscular (IM) Injection **WORK // DOC**

Procedure Goal: To administer an intramuscular injection safely and effectively, using sterile technique

OSHA Guidelines:

Materials: Patient chart/progress note, drug order (in patient's chart), alcohol swabs, sterile 2×2 gauze or cotton ball, container of the ordered drug, disposable needle and syringe of the appropriate size, sharps container

Method:

1. Identify the patient. Wash your hands and put on exam gloves.
2. Check the rights, comparing information against the drug order.
RATIONALE: *To ensure necessary accuracy.*
3. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.
4. Prepare the drug and draw it up to the mark on the syringe that matches the ordered dose.

FIGURE Procedure 53-7 Step 5 Gently tap the site to stimulate the nerve endings.

© McGraw-Hill Education

5. Choose a site and gently tap it. Tapping stimulates the nerve endings and reduces pain caused by the needle insertion.
6. Clean the site with an alcohol swab, moving in a circle from the center out. Let the site dry.
7. Stretch the skin taut over the injection site between the thumb and forefinger. For pediatric and geriatric patients, you can grasp the tissue and "bunch up" the muscle. For a Z-track, stretch and hold the skin and fat laterally.

8. Hold the needle and syringe at a 90-degree angle to the skin; then insert the needle with a quick, dart-like thrust.
RATIONALE: *The angle of the needle helps ensure that the medication is administered into the correct location.*
9. Release the skin and aspirate by pulling back slightly on the plunger to check the needle placement. If pulling back on the plunger produces blood, placement is incorrect and you must draw up new medication again with a fresh needle and syringe. If pulling back on the plunger produces no blood, placement is correct. Inject the drug slowly.
RATIONALE: *Injecting an intramuscular drug into the bloodstream can cause severe adverse effects for the patient.*

10. After the full dose of the drug has been injected, place a 2 × 2 gauze over the site which is held in your non-dominant hand during the injection; then quickly remove the needle at a 90-degree angle.
11. Use the 2 × 2 gauze to apply pressure to the site and massage it, if indicated.
12. Properly dispose of used materials and the needle and syringe.
13. Remove the gloves and wash your hands.
14. Stay with the patient to monitor for unexpected reactions.
15. Document the injection in the patient's chart with date, time, drug name, dosage, expiration date, lot number, manufacturer, route, site, significant patient reactions, and any patient education.

PROCEDURE 53-8 Administering Inhalation Therapy

WORK // DOC

Procedure Goal: To administer inhalation therapy safely and effectively

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Patient chart/progress note, drug order (in patient's chart), container of the ordered drug, tissues, package insert or patient education sheet about medication

Method:

1. Identify the patient. Wash your hands.
2. Check the rights, comparing information against the drug order. Make sure you have the correct type of inhaler based on the order (oral or nasal).
RATIONALE: *To ensure necessary accuracy.*
3. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.
4. Prepare the container of medication as directed. Use the package insert and show the directions to the patient.
5. Shake the container as directed and stress this step to the patient.
RATIONALE: *The drug must be evenly distributed in the inhaler to ensure its effectiveness.*

Nasal Inhaler

6. Instruct the patient to
 - Blow your nose to clear the nostrils.
 - Tilt the head back and, with one hand, place the inhaler tip about ½ inch into the nostril.
 - Point the tip straight up toward the inner corner of the eye.**RATIONALE:** *Angling the inhaler downward makes the drug run down the back of the throat, causing a burning sensation.*
 - Use the opposite hand to block the other nostril.
 - Inhale gently while quickly and firmly squeezing the inhaler.

- Remove the inhaler tip and exhale through the mouth.
- Shake the inhaler and repeat the process in the other nostril.
- Keep your head tilted back and do not blow your nose for several minutes (if indicated in the package insert).

Oral Inhaler

7. Instruct the patient to
 - Warm the canister by rolling it between the palms of your hands.
 - Uncap the mouthpiece and assemble the inhaler as directed on the package insert.
 - Hold your mouth open and place the canister in your mouth or about 1 inch from your mouth. Check the package insert for the proper placement.
 - Exhale normally and inhale through the canister as you depress it. The medication must be inhaled.
 - Breathe in until your lungs are full and hold your breath for 10 seconds.
 - Breathe out normally.

After You Have Given an Inhalation Medication

8. Remain with the patient to monitor for changes and possible adverse reaction.
9. Recap and secure the medication container. Instruct the patient in this procedure.
10. Wash your hands.
11. Give the patient an information sheet about the drug. Discuss the information with the patient and answer any questions. If the patient has questions you cannot answer, refer her to the licensed practitioner.
12. Document the drug administration in the patient's chart with date, time, drug name, dosage, expiration date, lot number, manufacturer, route, site, significant patient reactions, and any patient education.

PROCEDURE 53-9 Administering and Removing a Transdermal Patch and Providing Patient Instruction

WORK // DOC

Procedure Goal: To safely administer a transdermal patch drug to and remove it from a patient

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Patient chart/progress note, drug order (in patient chart), transdermal patch medication, gloves, package insert or drug information sheet

Method:

1. Identify the patient, wash your hands, and put on gloves.
RATIONALE: *Gloves prevent the medication from being absorbed through your skin.*
2. Select the ordered transdermal patch and check the rights, comparing information against the drug order.
RATIONALE: *To ensure necessary accuracy.*
3. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.
RATIONALE: *To prevent a reaction to the medication.*
4. If you are unfamiliar with the drug, check the PDR or other credible drug reference, read the package insert, or speak with the licensed practitioner. The package insert is extremely detailed for transdermal medications and should be used when applying the medication and/or doing patient teaching.
5. Perform any calculations needed to provide the prescribed dose. If you are unsure of your calculations, check them with a coworker or the licensed practitioner.

Applying the Transdermal Medication

6. Remove the patch from its pouch. The plastic backing is easily peeled off once the patch is removed from the pouch. For patches without a protective pouch, bend the sides of the transdermal unit back and forth until the clear plastic backing snaps down the middle.
7. For either type of patch, demonstrate how to peel off the clear plastic backing to expose the sticky side of the patch.
8. Apply the patch to a reasonably hair-free site, such as the abdomen. Note that estrogen patches are usually placed on the hip.
9. Instruct the patient on how to apply the patch. Tell the patient that if she is applying the patch, she does not have to wear gloves, but if a caregiver or any other third party applies the patch, that person must wear gloves to avoid absorbing the medication through the skin. Advise the patient to avoid using the extremities below the knee or elbow, skinfolds, scar tissue, or burned or irritated areas.
RATIONALE: *These areas do not absorb the medication as well because of the reduced blood supply.*

FIGURE Procedure 53-9 Steps 6–8 To apply a transdermal patch, first (1) either remove it from the pouch or bend the sides back and forth until the backing snaps; then (2) peel the backing off the patch and (3) apply the patch, sticky side down, to a clean, relatively hairless site.

Removing the Transdermal Patch

10. Gently lift and slowly peel the patch back from the skin. Wash the area with soap and dry it with a towel. Instruct the patient on this technique.
11. Explain to the patient that the skin may appear red and warm, which is normal. Reassure the patient that the redness will disappear. In some cases, lotion may be applied to the skin if it feels dry.
12. Instruct the patient to notify the licensed practitioner if the redness does not disappear in several days or if a rash develops.
13. *Never* apply a new patch to the site just used. It is best to allow each site to rest between applications. Some transdermal systems call for waiting 7 days before using a site again. Be sure to check the package directions regarding site rotation.

After You Have Applied and/or Removed the Transdermal Patch

14. Wash your hands and instruct the patient to do the same after applying or removing a transdermal system at home.

15. Give the patient an information sheet about the drug. Discuss the information with the patient and answer any questions. If the patient has questions you cannot answer, refer her to the licensed practitioner.

16. Document the drug administration in the patient's chart with date, time, drug name, dosage, expiration date, lot number, manufacturer, route, site, significant patient reactions, and any patient education.

PROCEDURE 53-10 Assisting with Administration of a Urethral Drug

WORK // DOC

Procedure Goal:

To assist with a urethral administration

OSHA Guidelines:

Materials: Patient chart/progress note, urinary catheter kit, either a syringe without a needle or tubing and a bag (depending on the amount of drug to be administered), sterile gloves, the prescribed drug, a drape, and a bedsaver pad

Method:

1. Wash your hands and use sterile technique to assemble the equipment.
2. Check the rights, comparing information against the drug order, and explain the procedure and the drug order to the patient.

RATIONALE: To ensure necessary accuracy.

3. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.
4. Assist the patient into the lithotomy position and drape her to preserve her modesty while exposing the vulva.
5. Place a bedsaver pad under the buttocks.
6. Open the catheter kit.
7. Put on sterile gloves.
8. Cleanse the vulva as you would to perform catheterization, using the materials in the kit. As you sweep down with the antiseptic swab, watch for the urethral opening to "wink."

RATIONALE: The wink is where the cleanser stimulates and fills the opening of the urethra, making it look like a

FIGURE Procedure 53-10 Step 4 Use the stirrups to place the patient in the lithotomy position. Clothing should be removed and a drape applied.

© McGraw-Hill Education

winking eye. Finding the wink helps you accurately locate the urethral opening.

9. The physician or nurse will insert the lubricated catheter. Tell the patient that she should feel pressure, not pain, and that the physician or nurse is going to attach the syringe to the catheter and insert the drug (or attach the tubing and bag to the catheter and let the drug run in by gravity).
10. After instilling the drug, the physician or nurse will clamp the catheter and leave the drug in place for the ordered amount of time.
11. Stay with the patient not only to ensure that she remains still but also to reassure her that the full feeling in the bladder is normal. She also may say she feels the need to urinate. Advise her that this feeling, too, is normal and is caused by the catheter.
12. When the time is up, unclamp the catheter, gently remove it, and allow the patient to urinate. Assist the patient as needed.
13. While the patient is dressing, immediately document the drug instillation with date, time, drug, dose, route, and any significant patient reactions.

PROCEDURE 53-11 Administering a Vaginal Medication

WORK // DOC

Procedure Goal: To safely administer a vaginal medication with patient instruction

OSHA Guidelines:

Materials: Patient chart/progress note, prescription or drug order in the patient's chart, a cloth or paper drape, a bedsaver pad, gloves, cotton balls, water-soluble lubricant, and the prescribed drug

Method:

1. Wash your hands.
2. Check the rights, comparing information against the drug order, and explain the procedure and the drug order to the patient.

RATIONALE: To ensure necessary accuracy.

3. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.
4. Give the patient the opportunity to empty her bladder before beginning.
5. Assist the patient into the lithotomy position and drape her.
RATIONALE: *To preserve her modesty while exposing the vulva.*
6. Place a bedsaver pad under the buttocks.
7. Put on gloves.
8. Cleanse the perineum with soap and water, using one cotton ball per stroke, and cleanse the center last, while spreading the labia.
RATIONALE: *This technique prevents contamination of areas already cleaned.*
9. Lubricate the vaginal suppository applicator in lubricant spread on a paper towel. For vaginal drugs in the form of creams, ointments, gels, and tablets, use the appropriate applicator, preparing it according to the package insert.
10. While spreading the labia with one hand, insert the applicator with the other (the applicator should be about 2 inches into the vagina and angled toward the sacrum).
11. Release the labia and push the applicator's plunger to release the suppository into the vagina.
12. Remove the applicator and wipe any excess lubricant off the patient.
13. Help her to a sitting position and assist with dressing if needed.
14. Document the administration with date, time, drug, dose, route, and any significant patient reactions.

PROCEDURE 53-12 Administering a Rectal Medication

WORK // DOC

Procedure Goal: To safely administer a rectal medication

OSHA Guidelines:

Materials: Patient chart/progress note, prescription or drug order in the patient's chart, a cloth or paper drape, a bedsaver pad, gloves, water-soluble lubricant, and the prescribed drug

Method:

1. Check the rights, comparing information against the drug order.
RATIONALE: *To ensure necessary accuracy.*
2. Explain the procedure and the drug order to the patient.
3. Ask the patient about any drug or food allergies. If the patient is not allergic to the ordered drug or other ingredients used to prepare it, proceed.
4. Give the patient the opportunity to empty the bladder before beginning.
5. With the patient in a gown, help the patient into Sims' position and use a drape to prevent exposing the patient. Place a bedsaver pad under the patient.

FIGURE Procedure 53-12 Step 5 Place the patient into Sims' position. The patient should be in a gown with a drape in place.

© McGraw-Hill Education

6. Lift the patient's gown to expose the anus.
7. Wash your hands, put on gloves, and prepare the medication.

Administering a Suppository

8. Lubricate the tapered end of the suppository with about 1 tsp of lubricant.
9. While spreading the patient's buttocks with one hand, insert the suppository—tapered end first—into the anus with the other hand.
10. Gently advance the suppository past the sphincter with your index finger. Before it passes the sphincter, the suppository may feel as if it is being pushed back out of the anus. When it passes the sphincter, it seems to disappear.
11. Use tissues to remove excess lubricant from the area.
12. Remove your gloves and ask the patient to lie quietly and retain the suppository for at least 20 minutes. When the treatment is completed, help the patient to a sitting, then standing, position.
RATIONALE: *To ensure the maximum effectiveness of the medication.*

Administering a Retention Enema

13. Place the tip of a syringe into a rectal tube. Let a little rectal solution flow through the syringe and tube. While holding the tip up, clamp the tubing.
14. Lubricate the end of the tube, spread the patient's buttocks, and slide the tube into the rectum about 4 inches.
15. Slowly pour the rectal solution into the syringe, release the clamp, and let gravity move the solution into the patient. When you have administered the ordered amount of solution, clamp the tube and then remove it.

16. Using tissues, apply pressure over the anus for 20 seconds to stifle the patient's urge to defecate, and then wipe any excess lubricant or solution from the area. Remove your gloves and encourage the patient to retain the enema for the time ordered.

RATIONALE: To ensure the maximum effectiveness of the medication.

17. When the time has passed, put on gloves and help the patient use a bedpan or direct the patient to a toilet to expel the solution.

After the Administration Is Complete

18. Remove your gloves and wash your hands.
19. Immediately document the drug administration with date, time, drug, dose, route, and any significant patient reactions.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
53.1 Describe the rules and responsibilities regarding drug administration and the initial preparation for drug administration.	Before administering a medication, you should check the patient for allergies and evaluate any drug-drug interactions. You should check all injection sites for abnormalities such as scars, bruises, burns, rash, edema, moles, birthmarks, traumatic injuries, redness, cyanosis, tattoos, warts, site of a mastectomy, and paralyzed areas. Additionally, you should be aware of the patient's condition and have the patient sign a consent form if necessary.
53.2 List the rights of drug administration.	The rights of drug administration include the right patient, right drug, right dose, right route, right time, right documentation, right reason, right to know, right to refuse, and right technique.
53.3 Recognize the correct equipment to use for administering medications.	Drugs may be administered for either local or systemic effects. Generally, drugs that have local effects are applied directly to the skin, tissues, or mucous membranes. Drugs that produce systemic effects are administered by routes that allow the drug to be absorbed and distributed in the bloodstream throughout the body. Table 53-2 outlines the many drug administration routes.
53.4 Carry out the procedures for administering oral medications.	Oral medications typically are swallowed and absorbed through the digestive tract. Sublingual medications go under the tongue, and buccal medications go between the cheek and gum.
53.5 Carry out procedures for administering parenteral medications by injection.	The three most common injection routes are ID, subcut, and IM. IV is less frequently used in a medical office. All injections are given using aseptic technique. Intradermal (ID) injections are administered between the upper layers of skin and create a wheal. Subcutaneous (subcut) injections are administered just under the skin, and intramuscular (IM) injections are administered into a muscle.
53.6 Carry out procedures for administering parenteral medications by other routes.	Other medication routes include inhalants (respiratory), topical (including transdermal), urethral, vaginal, and rectal.

LEARNING OUTCOMES	KEY POINTS
53.7 Relate special considerations required for medication administration to pediatric, pregnant, breast-feeding, and geriatric patients.	Certain special considerations must be made when caring for pediatric, pregnant, and breast-feeding patients. Pediatric patients require extreme care when calculating doses due to the differences in how their bodies absorb, metabolize, eliminate, and distribute the medications. Treat pediatric patients with special care and communication to make the experience as positive as possible. Restraining may be necessary. Checking medications given to pregnant and breast-feeding patients for possible adverse effects is essential. Geriatric considerations are discussed in the <i>Assisting in Geriatrics</i> chapter.
53.8 Outline patient education information related to medications.	Patients should be educated about why, when, and how they should take medications. This includes instruction to ensure patient compliance regarding nonprescription and prescription drugs as well as herbal remedies and supplements. Patients also should be instructed about the dangers of medication combinations, the importance of reporting an adverse effect, and the maintenance of a complete medication list.
53.9 Implement accurate and complete documentation of medications.	Documentation of medication administered should occur immediately after the medication is given and should include name, date, time, medication administered, dose, route, location, lot number, and how the patient tolerated it.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall John Miller from the beginning of the chapter. Now that you have completed this chapter, answer the following questions regarding his case.

1. What questions do you need to ask Mr. Miller during his initial interview regarding his medications?
2. When you get ready to administer the pneumococcal immunization, Mr. Miller states that he had a bad reaction the last time he received a shot. What should you do?
3. If the site of the injection from his last visit was just irritated due to the medication, what could be done to reduce the irritation for his next IM injection?

EXAM PREPARATION QUESTIONS

1. (LO 53.3) Which of the following would you expect to be absorbed in the *least* amount of time?
 - a. 200 mL of D5W IV
 - b. 5 mL of Compazine® IM
 - c. 325 mg of ASA orally
 - d. ii puffs of albuterol by oral inhalation
 - e. PPD subcut injection
2. (LO 53.2) Which of the following is *not* a basic right of medication administration?
 - a. Right dose
 - b. Right drug
 - c. Right to refuse
 - d. Right patient
 - e. Right time

3. (LO 53.8) Which of the following patients has the greatest risk of overdose and toxicity from a medication?
 - a. A 35-year-old woman
 - b. A 6-year-child with the flu
 - c. A 50-year-old male with hypertension
 - d. A 16-year-old Hispanic girl with mononucleosis
 - e. A 25-year-old man with diabetes
4. (LO 53.1) When performing a triple check, which of the following would you *least* likely do?
 - a. *1st check*—when you take it from the storage container and match it to the MAR
 - b. *2nd check*—when you prepare it
 - c. *3rd check*—before you close the storage container
 - d. *3rd check*—just after you administer the drug
 - e. *3rd check*—just before you administer the drug
5. (LO 53.4) A patient is taking a nitroglycerin tablet under his tongue. What route of administration is this?
 - a. Urethral
 - b. Topical
 - c. Inhalant
 - d. Sublingual
 - e. Buccal
6. (LO 53.5) You are injecting a medication ID; what would *best* let you know that you have done it correctly?
 - a. The patient does not have pain
 - b. There is a wheal on the skin at the site
 - c. The angle of the needle is at 90 degrees
 - d. The medication went into a muscle
 - e. The medication went under the skin
7. (LO 53.6) You are administering a suppository. What route of administration are you performing?
 - a. Oral
 - b. Vaginal
 - c. Respiratory
 - d. IV
 - e. Topical
8. (LO 53.7) An infant needs an immunization subcut. What site and what needle would be your *best* choice?
 - a. Vastus lateralis, 20 gauge, 5/8 inch
 - b. Vastus lateralis, 25 gauge, 1½ inch
 - c. Ventrogluteal, 25 gauge, 5/8 inch
 - d. Dorsogluteal, 23 gauge, 1 inch
 - e. Vastus lateralis, 25 gauge, 5/8 inch
9. (LO 53.8) Which of the following would be done to improve patient compliance?
 - a. Have patients with multiple meds create an alarm, calendar, or chart
 - b. Remind patients taking antibiotics to stop once they are feeling better
 - c. To avoid waste, encourage patients to share medication if they have too much
 - d. Dispose of expired drugs 1 year after the expiration date on the medication
 - e. Encourage anxious patients to have at least three servings of alcohol each day
10. (LO 53.9) Which of the following is the most complete medication documentation?
 - a. Gave Demerol® for pain at 2 pm
 - b. Demerol® 100 mg IM in deltoid
 - c. 4/12/XX Demerol® IM in left deltoid
 - d. 4/12/XX Phenergan® 200 mg PO for nausea
 - e. Phenergan® PO for nausea—Kaylyn R. Haddix RMA(AMT)

Go to CONNECT to see activities on *Documenting Medication Administration and Managing Patient Prescriptions*.

SOFT SKILLS SUCCESS

While working at BWW Associates with a medical assisting student from a local school, you enter an examination room with a patient and notice there is a small needle and syringe with medication in it on the tray table. You know that it was the medical assisting student's responsibility to clean the room between patients. What should you do?

Go to PRACTICE MEDICAL OFFICE and complete the module Clinical – Office Operations.

Physical Therapy and Rehabilitation

54

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Chris Matthews	11/19/20XX	NKA
	Attending	MRN	Other Information
	Alexis N. Whalen, MD	324-95-786	AP and lateral X-ray right ankle show no signs of fractures.

Chris Matthews is an 8-year-old male patient who arrives at the office with a swollen right ankle. Chris was climbing a tree this morning and jumped from a lower limb to the ground. When he landed, he felt his ankle “turn over” and he could not stand up. Chris’s mother tells you that she thinks it was about 6 feet from the limb to the ground. She also tells you that she put ice on Chris’s ankle after she brought him into the house but his ankle just kept swelling and Chris

© McGraw-Hill Education

still cannot walk. She says that his ankle is badly bruised. Mrs. Matthews is very distraught and asks that Chris be seen immediately. You speak with Dr. Whalen, and she asks you to take Chris to the X-ray department for X-rays. Dr. Whalen examines Chris and reads the X-rays. She wraps Chris’s ankle and tells you Chris has a badly sprained ankle and will need crutches for a few

weeks using a non-weight-bearing gait.

Keep Chris in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 54, you will be able to:

- 54.1** Discuss the general principles of physical therapy.
- 54.2** Relate various cold and heat therapies to their benefits and contraindications.
- 54.3** Recall hydrotherapy methods.
- 54.4** Name several methods of exercise therapy.
- 54.5** Describe the types of massage used in rehabilitation therapy.
- 54.6** Compare different methods of traction.
- 54.7** Carry out the procedure for teaching a patient to use a cane, a walker, crutches, and a wheelchair.
- 54.8** Model the steps you should take when referring a patient to a physical therapist.

KEY TERMS

- | | |
|---------------|-----------------------|
| cryotherapy | mobility aid |
| diathermy | physical therapy |
| erythema | posture |
| fluidotherapy | range of motion (ROM) |
| gait | therapeutic team |
| goniometer | thermotherapy |
| hydrotherapy | traction |

- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.9** Assist provider with a patient exam
- I.A.1** Incorporate critical thinking skills when performing patient assessment
- I.A.2** Incorporate critical thinking skills when performing patient care
- V.C.6** Define coaching a patient as it relates to:
 - (c) compliance with treatment plan
 - (e) adaptations relevant to individual patient needs
- V.P.4** Coach patients regarding:
 - (d) treatment plan
- XII.C.7** Identify principles of:
 - (a) body mechanics
 - (b) ergonomics

2. Anatomy and Physiology

- c. Identify diagnostic and treatment modalities as they relate to each body system

9. Clinical Procedures

- d. Assist provider with specialty examination including cardiac, respiratory, OB-GYN, neurological, gastroenterology procedures
- e. Perform specialty procedures including but not limited to minor surgery, cardiac, respiratory, OB-GYN, neurological, gastroenterology
- j. Make adaptations with patients with special needs

► Introduction

Applying cold and heat therapy and assisting patients with ambulation (walking around) are common responsibilities of a medical assistant. These activities are part of the physical therapy field. For a full program of physical therapy, a physician generally refers a patient to a licensed physical therapist. However, a physician may request that you assist with some forms of physical therapy, including

- Applying cold and heat.
- Teaching basic exercises.
- Demonstrating how to use a cane, a walker, and crutches.
- Demonstrating how to use a wheelchair.
- Discussing with the patient specific therapies for use at home.

► General Principles of Physical Therapy

LO 54.1

Physical therapy is a medical specialty for the treatment of musculoskeletal, nervous, and cardiopulmonary disorders. A physical therapist uses a variety of treatments, including cold, heat, water, exercise, massage, and traction. Some physical therapy regimens combine two or more treatments. Exercising in a pool, for example, combines the use of water and exercise. In addition, the physical therapist actively promotes patient education and rehabilitation programs.

Physical therapy benefits patients in several ways. It restores and improves muscle function, builds strength, increases joint mobility, relieves pain, and increases circulation. Physical therapy is used to treat various disorders, including arthritis, stroke, lower back pain, muscle spasms, muscle injuries or diseases, pressure sores, skin disorders, and burns.

Assisting Within a Therapeutic Team

Many people who require physical therapy are recovering from traumatic injuries or dealing with chronic illnesses, so they may be receiving therapeutic attention from several specialists. Physicians, nurses, medical assistants, and other specialists who work with patients dealing with chronic illness or recovery from major injuries make up a **therapeutic team**. When you work with such patients, your responsibilities may include

- Coordinating the patient's schedule of sessions with different specialists.
- Making referrals, as directed by the physician.
- Explaining a specialist's treatment approach to the patient.
- Communicating the physician's findings to the specialist.
- Documenting the specialist's treatments and findings for the physician.
- Reinforcing the specialist's instructions for the patient.
- Answering the patient's questions.

To fulfill these responsibilities, you must have a working knowledge of therapy techniques. If, for example, the physician refers a patient to an art therapist, you would set up an art therapy appointment and explain in general terms what the patient can expect. The *Educating the Patient* feature offers basic information about various specialized therapies.

Besides learning the basic information you need to know about physical therapy, you will want to keep up-to-date on emerging techniques. You may want to become proficient in some of these new techniques. By expanding your knowledge and skills, you increase your value as a member of the therapeutic team.

Assisting with Patient Assessment

Before the doctor prescribes physical therapy, she assesses the patient's physical abilities and condition. She inspects and palpates the patient's joints and muscles and tests the patient's

EDUCATING THE PATIENT

Specialized Therapies and Their Benefits

Healthcare professionals recognize the contribution of specialized therapies to a patient's recovery. Because many people do not know about these specialized therapies, you may be called on to explain them to patients. You can educate patients about potential benefits of art therapy or other specialized therapies. When specialized therapies are ordered, patients will be more at ease if they know what to expect. You can help when necessary by explaining the following types of therapies and their advantages.

- In art therapy, patients learn to express themselves visually through drawing, painting, and sculpture. Art therapy aids both physical and mental healing, provides a recreational outlet, improves mobility and fine motor coordination, provides an outlet for expressing fears or other emotions patients may be unaware of or unable or unwilling to express verbally, helps relieve anxiety, allows patients to focus on something other than their physical condition, and encourages patients to take better care of themselves. To aid in the art therapy process, encourage patients to relax and give this approach time to work. Although the benefits of art therapy may be evident immediately, they are just as likely to be perceived only after the course of therapy is well under way.
- In music therapy, patients listen to and create music to help them relax and alleviate anxiety. This therapy is often used with surgical patients and patients with chronic pain.
- In dance therapy, patients participate in dance to improve balance, flexibility, strength, and quality of life.
- In writing therapy, patients express themselves through a chosen form of writing, such as composing poetry or keeping a journal.
- In crafts therapy, patients express themselves by using a variety of media to create handiworks.
- In pet therapy, patients play with, groom, or walk a pet. Pets provide companionship and the opportunity to nurture.
- In aquatic therapy, patients swim in a therapeutic pool equipped with a ramp and a lift so that it is accessible to all. Many patients who cannot walk on land can move their legs remarkably well in water.
- In horticultural therapy, patients work with plants and flowers to bring beauty into their daily lives and to help improve their balance, strength, memory, and socialization skills.
- In equestrian therapy, patients ride horses to develop strength, coordination, and muscle tone and to improve balance.

joint mobility, muscle strength, gait, and posture. You will typically assist with these tests. In some cases, the doctor may direct you to perform them.

Joint Mobility Testing People usually assume their joints are mobile until stiffness or injury limits them. When a patient complains of these difficulties, the doctor may ask you to assist in testing range of motion. **Range of motion (ROM)** is the degree to which a joint is able to move, measured in degrees with a protractor device called a universal **goniometer** (Figure 54-1). The measurement of joint mobility, known as *goniometry*, is a noninvasive test frequently performed in doctors' offices, requiring the patient to move each major joint in various ways. The specific movements evaluated are described in Figure 54-2. Review the chapter *The Muscular System* for more information about body movement. The doctor may ask you to assist with goniometry and, after special training, you may be asked to perform it. When performing goniometry, you measure the joints from the head to the feet, comparing each joint measurement with a standard measurement (in degrees of movement) for that joint.

Muscle Strength Testing The physician tests muscle strength to determine the amount of force the patient is able to exert with a muscle or group of muscles. This test—usually done at the same time as ROM testing—may be performed by the physician with your assistance or, once you

have had special training, the physician may ask you to perform it yourself.

Like the ROM test, the muscle strength test is usually done from head to foot. The patient is asked to resist the pressure that you or the physician applies to each muscle or group of muscles (usually near a joint). Strength is rated on a five-point scale.

FIGURE 54-1 A universal goniometer is a protractor with a movable pointer that measures degrees of joint movement.

FIGURE 54-2 When you measure joint ROM, begin at the head and work down to the feet.

(continued)

Typically, a patient can move a joint a certain distance and can easily resist the pressure you apply. The patient usually has equal strength on both sides of the body. If there is weakness, however, a medical problem may be indicated. The physician must be made aware of weaknesses so that he can use this information to develop a treatment plan.

Gait Testing Gait is the way a person walks. Generally, a physician or physical therapist assesses a patient's gait. To do so, the physician asks the patient to walk away, turn around, and walk back. Assessment of gait includes an appraisal of the patient's length of stride, balance, coordination, direction of knees (inward or outward), and direction of feet (inward or outward).

Posture Testing Posture is body position and alignment. The doctor assesses posture by looking at the patient's spinal curve from the sides, back, and front. Normally, the thoracic spine has a convex (outward) curve and the lumbar spine has a concave (inward) curve. The doctor also notes the symmetry of alignment of the shoulders, knees, and hips.

To assess alignment and degree of straightness of the spine, the doctor asks the patient to bend at the waist and let the arms dangle freely. To assess knee position, the doctor asks the patient to stand with both feet together to determine whether the knees are at the same height, facing forward, and symmetrical.

FIGURE 54-2 When you measure joint ROM, begin at the head and work down to the feet.

► Cryotherapy and Thermotherapy LO 54.2

Applying cold to a patient's body for therapeutic reasons is called **cryotherapy**. This type of therapy can be administered in a number of ways. Treatments may be dry or wet, and they may be chemical or natural. Examples of dry cold applications are ice bags and ice packs. Wet cold applications include cold compresses and ice massage.

Applying heat to a patient's body for therapeutic reasons is called **thermotherapy**. As with cryotherapy, thermotherapy can be administered in a variety of ways. Examples of devices

used in dry heat treatments are electric heating pads, hot-water bottles, and heat lamps. Moist heat treatments include hot soaks and the use of hot compresses and hot packs.

Factors Affecting the Use of Cryotherapy and Thermotherapy

A healthcare practitioner takes several things into consideration before choosing a cold or heat therapy for a patient:

- The purpose of the therapy
- The location and condition of the affected area

TABLE 54-1 Contraindications, Precautions, and Side Effects Related to Cold and Heat

Therapy	Precautions	Contraindications	Side Effects
Dry and moist cold applications	Poor circulation, extreme age or youth, arthritis, and impaired sensation (insensitivity to cold)	Severe circulatory problems, inability to tolerate weight of device, and pain caused by application (more common with moist cold)	Numbness, pain, very pale or bluish skin, and blood clots (rare)
Dry and moist hot applications	Impaired kidney, heart, or lung functions; atherosclerosis; impaired sensation (insensitivity to heat); extreme age or youth; and pregnancy	Possibility of hemorrhage, malignancy; acute inflammation, like appendicitis; severe circulation problems; and pain caused by the weight of the device	Burns (especially with heat lamps), increased respiratory rate, and lowered blood pressure

- The patient's age
- The patient's general health

After choosing a therapy, the physician may direct you to apply the cold or heat treatment and to teach the patient and family how to continue the therapy at home.

Performed correctly, cold and heat therapies generally promote healing. These therapies can, however, cause side effects in some patients, so you need to exercise caution when applying the therapies. Cold therapy can cause damage to underlying nerves and tissues if applied incorrectly or for too long. Heat therapy can cause burns to the skin and underlying tissues if incorrectly applied. Monitor the patient carefully for signs of tissue damage, which include extreme blanching, redness, or blistering of the skin. You also need to be aware of conditions that contraindicate (make inadvisable) cold or heat therapies. Table 54-1 summarizes circumstances that warrant precautions or contraindications for the therapies and possible side effects. When performing any cold or heat therapy, you should consider the treatment location, any patient problems with circulation or sensation, individual temperature tolerance, and the patient's age.

Treatment Location Thin-skinned areas often covered with clothing (such as the back, chest, and abdomen) are more sensitive to cold and heat therapies than other areas, such as the face and hands. Use caution around any broken skin (as with a wound) because it is susceptible to further tissue damage from cryotherapy or thermotherapy.

Circulation or Sensation Impairment Patients with diabetes or cardiovascular disease may have impaired circulation or sensory perception. These impairments may prevent such patients from sensing that a treatment is too cold or too hot. These patients require close monitoring during cryotherapy or thermotherapy. Carefully observe their skin to determine the treatment's therapeutic effect.

Temperature Tolerance Tolerance of temperature extremes varies greatly from person to person. Some people are unusually sensitive to cold or to heat. Listen carefully to patients for any indication of temperature intolerance during treatment. Cases of intolerance should be reported to the physician, who may decide to change the treatment.

Elderly Patients' Sensitivity to Cold and Heat Age is an important consideration when using cryotherapy and

thermotherapy. Elderly patients are usually more sensitive than others to cold and heat. They may have poor circulation; arthritis; impaired sensation; kidney, heart, or lung disease; or atherosclerosis. They also may have impaired skin integrity—thinning of the skin, resulting in increased risk of skin tear, bruising, and burning. When administering cryotherapy or thermotherapy, stay with an elderly patient during its application to check the patient's skin frequently for excessive paleness or redness.

Principles of Cryotherapy

The application of cryotherapy causes blood vessels to constrict and involuntary muscles of the skin to contract. These physiologic responses can:

- Prevent swelling by limiting edema, or fluid accumulation in body tissue.
- Control bleeding by constricting blood vessels.
- Reduce inflammation by slowing blood and fluid movement in the affected area.
- Provide an anesthetic effect for pain by reducing inflammation.
- Reduce pus formation by inhibiting microorganism activity.
- Lower body temperature.

Administering Cryotherapy

Cryotherapy is highly effective in alleviating swelling, pain, inflammation, and bleeding caused by various types of injuries. For best results, cryotherapy should be used frequently (about 20 minutes every hour) for the first 48 hours after an injury. As cold is applied, the skin becomes cool and pale because blood vessels constrict, decreasing the blood supply to the area. The decreased blood supply also reduces tissue metabolism, oxygen use, and waste accumulation.

Dry Cold Applications Dry cold applications include ice bags, ice collars, and chemical ice packs. An ice bag is a rubber or plastic bag with a locking lid. An ice collar is a rubber or plastic kidney-shaped bag curved to fit around the back of the neck. A chemical ice pack is usually a flat plastic bag containing a semifluid chemical (Figure 54-3). Ice packs come in various sizes and types; some are disposable and others can be stored in a freezer and reused. The chemical prevents them from freezing solid, allowing them to be molded to the area to

FIGURE 54-3 This chemical pack can be frozen, boiled, or microwaved for cold and heat therapy.

© Total Care Programming, Inc.

be treated. Chemical ice packs may require squeezing or shaking to activate the cooling action. Most packs remain cold for 30 to 60 minutes. Some ice packs come with a soft covering; others must be wrapped in a cloth before they are applied to the skin.

Wet Cold Applications Wet cold applications include cold compresses and ice massage. A cold compress is a cloth or gauze pad moistened with ice water. It may be used to treat the pain associated with a toothache, tooth extraction, eye injury, or headache. The ice used in ice massage may be a cube wrapped in a plastic bag or water frozen in a paper cup. The combination of the cold temperature and the motion of the massage can provide therapeutic relief for the localized pain resulting from a sprain or strain. Although cold causes muscles to contract, the pain-relieving effect can help a patient relax. The procedure for administering cryotherapy is outlined in Procedure 54-1 at the end of this chapter.

Principles of Thermotherapy

The application of thermotherapy causes blood vessels to dilate (expand), which increases the blood supply to the area. Increased blood supply brings about an increased tissue metabolism that carries oxygen and nutrients to the cells of the area being treated. Increased metabolism carries toxins and wastes away from the cells. During thermotherapy, the treated skin becomes warm and develops **erythema** (redness) as the capillaries in the skin's deep layers fill with blood. These physiologic responses can have the following results:

- Relief of pain and congestion
- Reduction of muscle spasms
- Muscle relaxation
- Reduction of inflammation
- Reduction of swelling by increasing the fluid absorption from the tissues

Administering Thermotherapy

Thermotherapy is highly effective in relieving pain, congestion, muscle spasms, and inflammation and promoting muscle

relaxation. However, if heat is applied for too long, it may increase skin secretions that soften the skin and lower its resistance to infection. Heat that is too extreme can burn the skin or increase edema. Always monitor patients receiving thermotherapy, particularly children and elderly patients. The three basic types of thermotherapy are dry heat, moist heat, and diathermy. The general principles for administering the following types of thermotherapy are outlined in Procedure 54-2 at the end of this chapter.

Dry Heat Therapies Several types of dry heat therapy are available. They include the use of chemical hot packs, heating pads, hot-water bottles, heat lamps with infrared or ultraviolet bulbs, and fluidotherapy.

Chemical Hot Pack A chemical hot pack is a disposable, flexible pack of chemicals that becomes hot when you activate it by kneading or slapping it. After activating the pack, cover it with a cloth and place it on the patient's skin in the area being treated. Chemical hot packs are pliable and conform to body contours. For best results, follow the manufacturer's directions.

Heating Pad A heating pad is a flat pad with electrical coils between layers of soft fabric. When turned on, the coils provide localized heat. The physician should specify the heating pad temperature (low, medium, or high) and the length of time the pad should be applied.

Before applying a heating pad, cover it with a pillowcase or towel, check to be sure the cord is not frayed, and plug it into an electrical outlet. Make sure the patient's skin is dry. Then turn on the pad and set the temperature selector switch to the specified temperature. The patient should never lie on top of a heating pad, as burns could result.

Hot-Water Bottle A hot-water bottle is a flat, flexible, plastic or rubber bottle with a stopper. Fill the bottle with hot water, using a thermometer to make sure the water temperature does not exceed 125°F. For children under the age of 2 years and for elderly patients, the temperature should range from 105°F to 115°F. For older children, a safe temperature is 115°F to 125°F. Fill the bottle halfway; then compress it to expel air. The half-filled bottle can conform to the area to be treated. A half-filled bottle is also lighter than a full one, so it is more comfortable for the patient. Cover the bottle with a cloth or pillowcase before you apply it.

After you apply the hot-water bottle, check with the patient to make sure the temperature is not too hot. Check the temperature frequently and replace the hot water as needed. Each time you remove the bottle, check the patient's skin to make sure it is merely warm to the touch.

Heat Lamp A heat lamp uses an infrared or ultraviolet bulb to provide heat. When the lamp is turned on, infrared rays heat and penetrate the skin's surface to a depth of 3 to 5 millimeters. To avoid burning the skin, place an infrared heat lamp 2 to 4 feet from the area being treated. Treatment usually lasts for 20 to 30 minutes or as directed by the physician.

Although ultraviolet rays produce little heat, they can burn the skin and damage the eyes. Ultraviolet rays are used to kill bacteria and promote vitamin D formation. They stimulate epithelial cells and cause blood vessels to overfill, increasing the skin's defenses against bacterial infections. Ultraviolet lamps are used to treat psoriasis, pressure sores, and wound infections.

Before recommending the use of an ultraviolet lamp, the physician assesses the patient's sensitivity and determines the treatment duration, which usually ranges from 30 seconds to a few minutes. The duration is usually increased in 10-second intervals. Because ultraviolet rays can burn the skin, monitor the patient closely. Do not leave the room during treatment. Both you and the patient must wear goggles to protect the eyes.

Fluidotherapy *Fluidotherapy* is a technique for stimulating healing, particularly in the hands and feet. The patient places the affected body part in a container of glass beads or other fine, granular particles that are heated and agitated with hot air. Although the therapy is dry, its effect is similar to that of a therapy using water.

Moist Heat Applications Moist heat is often used to increase circulation and decrease pain to specific body areas, especially muscles and tendons. Moist heat applications include hot soak, hot compress, hot pack, and paraffin bath.

Hot Soak With hot-soak therapy, the patient places the affected body part—usually an arm or a leg—in a container of plain or medicated water that has been heated to no more than 110°F. A hot soak should last about 15 minutes.

Hot Compress A compress is a piece of gauze or cloth suitable for covering a small area. After soaking the compress in hot water, wring it out and apply it to the area to be treated. Keep the compress warm either by placing a hot-water bottle on top of it or by frequently rewarming the compress in hot water.

Hot Pack A hot pack is a large canvas bag filled with a heat-retaining gel that is used on a large body area. Like a hot compress, a hot pack retains heat after being placed in hot water.

Paraffin Bath A paraffin bath is a receptacle of heated wax and mineral oil. It is used to reduce pain, muscle spasms, and stiffness in patients with arthritis and similar disorders. The patient's affected area should first be washed. Then it is dipped repeatedly into the mixture until the area is covered with a thick coat of wax. The wax remains on the area for about 30 minutes and then is peeled off. Particularly useful for joints, especially the hands and feet, the paraffin bath has the added benefit of leaving the skin warm, flexible, and soft. Some erythema may result.

Alternating Hot and Cold Packs A physician may order application of a hot pack followed by a cold pack. This increases circulation to the area by dilating and constricting

the blood vessels. Be sure to apply the hot pack first. Applying the cold pack first can numb the skin and keep the patient from recognizing a hot pack is too hot. This can result in serious skin burns.

Diathermy *Diathermy* is a type of heat therapy in which a machine produces high-frequency electromagnetic waves that create deep heat penetration in muscle tissue. The heat helps decrease joint stiffness, dilate blood vessels, relieve muscle spasms, and reduce discomfort from sprains and strains. Three types of diathermy are ultrasound, shortwave, and microwave. Equipment for these therapies is continually being improved. Be sure to familiarize yourself with the manufacturer's instructions regarding the specific equipment in your office.

Ultrasound Ultrasound is the most common type of diathermy, used to treat sprains, strains, and other acute ailments. It projects high-frequency sound waves that are converted to heat in muscle tissue.

Ultrasound diathermy may be administered by rubbing a gel-covered transducer over the skin in circular patterns. It also may be administered to a body part under water. Do not use ultrasound in areas where bones are near the skin's surface, as this could cause bone damage.

Shortwave Shortwave diathermy uses radio waves that travel through the body between two condenser plates and are converted to heat in the tissues. This type of diathermy is used to treat acute, subacute, and chronic inflammation. Treatment typically ranges from 20 to 30 minutes. Do not use shortwave diathermy on a patient who has a pacemaker.

Microwave Microwave diathermy uses microwaves to provide heat deep in body tissues. Contraindications include use on patients with pacemakers, use in combination with wet dressings, and use in high dosages on patients with swollen tissue. Also, never use microwave diathermy near metal implants because the reaction between metal and microwaves could cause burns.

► Hydrotherapy

LO 54.3

Hydrotherapy is the use of water to treat physical problems. It is typically performed in the physical therapy department of a hospital, in an outpatient clinic, or at home. Common forms of hydrotherapy include the use of whirlpools and contrast baths and underwater exercises.

Whirlpools

Whirlpools are tanks in which water is agitated by jets of air under pressure. Whirlpools vary in size from small (capable of accommodating only one body part) to very large (capable of accommodating a wheelchair or full-body submersion). The agitated water's action in a whirlpool generates a hydromassage, which relaxes muscles and increases circulation. Whirlpools also are used to cleanse and debride (remove foreign matter and dead tissue from) the skin of patients with wounds, ulcers, or burns.

Contrast Baths

Contrast baths are separate baths, one filled with hot water and the other with cold water. The patient alternately moves the treated body part quickly from one bath to the other. This treatment induces relaxation, stimulates improved circulation (which speeds up healing), and results in greater mobility.

Underwater Exercises

Underwater exercises—prescribed for patients with joint injuries, burns, and arthritis—are usually performed in a warm swimming pool. Because the water’s buoyancy takes pressure off the joints, these exercises are particularly useful for patients with painful or limited movement. Combined with the movement of the water around the body, the exercises promote relaxation and increased circulation.

Exercise Therapy

LO 54.4

For many patients, exercise is as important as medications or other treatments and offers both preventive and therapeutic benefits. As a patient ages, exercise helps promote flexibility, mobility, muscle tone, and strength. Exercise is a primary treatment for fractures, arthritis, and some respiratory disorders; it can minimize symptoms or help slow disease progression. For patients who have had surgery, stroke, burns, or amputation, regular exercise therapy can help prevent problems caused by inactivity.

A doctor orders exercise therapy for many reasons. Exercise improves or restores general health and is especially therapeutic when a patient is weak from illness. Explain to patients that exercise will help them to:

- Improve muscle tone and strength.
- Regain ROM after an injury.
- Prevent ROM from diminishing in chronic conditions.
- Prevent or correct physical deformities.
- Promote neuromuscular coordination.
- Improve circulation.
- Relieve stress.
- Lower cholesterol levels.
- Aid in the resumption of normal daily activities.

Commonly used for treating sports injuries, exercise therapy for injured athletes is described in the *Educating the Patient* feature. This type of therapy focuses primarily on regaining muscle strength and flexibility in the injured area.

Role of the Medical Assistant

As a medical assistant, you may have several roles in exercise therapy. As an information resource for the patient and family, you must understand various types of exercise programs and the patient’s specific treatment plan. You also may serve as a source of support and encouragement when exercise programs are long and difficult. You may, for example, assist with ROM exercises and teach the patient and family how to perform them at home.

When teaching patients about exercises, give them illustrations of the exercises. Include with each illustration written instructions on the number of times to perform the exercise, as prescribed by the doctor.

After demonstrating each exercise, have patients perform it while you watch and give direction. Patients are more likely to perform exercises properly at home if they can perform them correctly in your presence. It is also helpful for patients’ caregivers or family members to watch and perform the exercises to become familiar with them.

Types of Exercise

There are various types of exercise in a therapeutic program; however, before a patient begins an exercise program, the doctor must evaluate the patient’s heart and lung function and overall physical condition. The doctor adjusts the level of exercise accordingly and may prescribe other forms of physical therapy, such as cryotherapy, thermotherapy, or hydrotherapy. Careful preparation by the doctor and patient before beginning an exercise therapy program helps prevent injuries. Some measures to prevent and treat common exercise therapy problems are outlined in Table 54-2.

Types of exercises in therapeutic programs include active mobility, passive mobility, aided mobility, active resistance, isometric, and ROM.

Active Mobility Exercises Active mobility exercises are exercises the patient performs without assistance to increase muscle strength and function. They often require equipment such as a stationary bicycle or a treadmill.

Passive Mobility Exercises In passive mobility exercises, the physical therapist or a machine moves a patient’s body part. The patient does not actively assist in these exercises. Patients who require passive mobility exercises may have neuromuscular disability or weakness. These exercises can help retain patients’ ROM and improve their circulation.

TABLE 54-2 Preventing and Treating Common Problems of Exercise Therapy

Problem	Prevention Methods	Treatment
Muscle strain	Beginning with gentle warm-up exercises	Rest and application of heat followed by ice
Muscle aches	Keeping track of the number of repetitions and amount of weight (resistance), if used; increasing the number of repetitions or amount of weight slowly	Rest and soaking in hot bath to relieve aches
Impatience with slowness of progress	Discussing expectations with patient; setting realistic goals with patient; stressing necessity of avoiding recurrent injury, which would prolong recovery	Creation of goal sheet, noting small successes as therapy progresses

EDUCATING THE PATIENT

The Injured Athlete

The risk of injury is associated with most sports, but some sports carry a greater risk of serious injury. Many sports-related injuries affect joints in the neck, shoulders, elbows, wrists, hands, knees, ankles, or feet.

You may be called on to educate injured athletes and to start them on the road to recovery. To do so, you need to understand the mind of the athlete. Why do many athletes get injured in the first place? Here are some reasons:

- The sport they participate in has a high injury rate.
- They return to a sport before their injuries are completely healed.
- They become impatient with a physical therapy regimen.
- They do not work at gradual muscle strengthening.

When does your job begin? After diagnosing the injury, the physician will probably refer the athlete to a sports medicine center or other physical therapy setting, where an individualized program will be set up. As a medical assistant, you will often be responsible for counseling an athlete about the physical therapy program she will be entering. Here are some basic rules you can communicate:

- Follow the physical therapy regimen set up by the physician or physical therapist—even if it is tedious or time-consuming.
- Use only the equipment specified by the therapist: free weights, weight-training equipment, stationary bike, other aerobic equipment, or swimming pool. The physical therapist recommends the designated equipment based

on the type of injury. Using other equipment could cause further injury or interfere with healing.

- Do not rush the therapy in an attempt to recover more quickly.
- Work slowly to strengthen muscles and improve flexibility.
- Continue exercises at home as instructed.
- Be patient.

Explain to the athlete how the physical therapy program will be presented. Knowing what to expect from the physical therapist can improve the athlete's compliance. Here are some explanations you might offer:

- The therapist will demonstrate exercises and then watch you perform them.
- The therapist may increase the number of repetitions or the amount of resistance (weight) but probably not both at the same time.
- The therapist will provide handouts illustrating the exercises, along with instructions on how to perform them.
- The therapist may provide an activity log to help you chart your progress.

An athlete who is impatient with a physical therapy regimen and returns to a sport before an injury has completely healed has an increased risk of repeated injury. Impress on the athlete the importance of the physical therapy process. Emphasize the need for gradual strengthening and healing over a period of time. To help the athlete in the long run, focus on recovery from injury and on the need to prevent recurrent injury.

Aided Mobility Exercises Aided mobility exercises are self-directed exercises. The patient performs them with the aid of a device such as an exercise machine or a therapy pool. Aided mobility exercises help retain or increase patients' ROM.

Active Resistance Exercises In active resistance exercises, the patient works against resistance (counter-pressure) to increase muscle strength. Resistance is provided manually by the therapist or mechanically by an exercise machine.

Isometric Exercises During isometric exercises, the patient relaxes and then contracts the muscles of a body part while in a fixed position. Isometric exercises can maintain the patient's muscle strength when a joint is temporarily or permanently immobilized.

ROM Exercises ROM exercises move each joint through its full range of motion. These exercises should be done slowly and gently. Doing them too quickly or too soon after an injury can cause pain, fracture, or bleeding into the joint. For this reason, a physical therapist assesses the patient and determines a recommended regimen of ROM exercises. You

may be asked to educate the patient and caregiver or family about the regimen.

ROM exercises are typically prescribed after a joint injury. The physical therapist may recommend that the joint be moved in its full range of motion three times, twice a day. ROM exercises are also recommended for elderly people, to improve circulation and muscle function. The therapist will prescribe one of three types of ROM exercises for patients:

1. Active range-of-motion exercises: performed by the patient without assistance
2. Assisted range-of-motion exercises: performed by the patient with the help of another person or a machine
3. Passive range-of-motion exercises: performed by another person or a machine

ROM exercises do not build muscle strength but do improve flexibility and mobility. Typical ROM exercises are illustrated in Figure 54-4.

Electrical Stimulation

Electrical stimulation helps prevent atrophy in muscles that cannot move voluntarily by causing the muscles to contract

(a)

(b)

(c)

(d)

FIGURE 54-4 A medical assistant helps a patient perform typical ROM exercises: (a) shoulder abduction, (b) back rotation, (c) hip flexion, and (d) toe abduction.

© David Kelly Crow

involuntarily (on impulse) and relax. Electrical stimulators deliver controlled amounts of low-voltage electric current to motor and sensory nerves to stimulate muscles. Frequent and regular electrical stimulation also aids in healing injured joints and in revitalizing muscles.

Electrical stimulation can help retrain a patient to use injured muscles by creating a perceivable connection between the stimulus (muscle movement) and the area of the brain that controls those muscles. If a limb does not function because of injury or disease, this therapy can give the patient hope that injured muscles are not dead. Hope often encourages a patient to work harder and to cooperate in the physical therapy regimen, which can be long and arduous.

Wearable electrical stimulation units are being developed for people with spinal cord injuries to help them retrain affected muscles.

► Massage

LO 54.5

The practice of massage uses pressure, kneading, stroking, vibration, and tapping to positively affect patients' health and well-being. Massage helps the patient relax and counteracts the effects of stress. During massage, the heart rate and blood pressure are lowered and blood circulation and lymph flow are increased. Massage helps reduce pain caused by tight muscles and helps relax muscle spasms.

FIGURE 54-5 Swedish massage uses kneading, pressure, stroking, and human touch to alleviate pain and promote healing through relaxation.
© McGraw-Hill Education/Shana Pritchard, photographer

Massage benefits the mind as well as the body: It helps improve concentration, promotes restful sleep, and helps the mind relax. Many patients find they handle daily stresses better when they have regular massage. People who get massages on a regular basis find they become ill less often and less severely and they feel less stressed and tense. Some patients notice their muscles beginning to tighten and are aware that if they get a massage, it will decrease muscle tension before it becomes severe.

Swedish Massage

Swedish massage is one of the best known and most frequently taught massage techniques. It stimulates circulation and lymph flow with five basic strokes that manipulate the body's soft tissues. The strokes include *pétrissage* (kneading), *effleurage* (stroking), *tapotement* (percussion), vibration, and friction. Oils and/or lotions are used to reduce friction on the patient's skin. One type of Swedish massage is done on warm muscles immediately after exercise. Another type is a stress-reduction massage that is done with the same basic strokes on patients who have not been exercising (Figure 54-5).

Neuromuscular Massage

Neuromuscular massage is applied to specific muscles and helps release tension and knots, relieve pain and release pressure on nerves, and increase blood flow. Trigger point therapy is one type of neuromuscular massage in which strong finger pressure is applied to trigger points in the muscles.

► Traction

LO 54.6

Traction is the pulling of the bones and joints to create a mechanical force that is used to treat fractured bones and dislocated, arthritic, or other diseased joints. It is often performed by a physical therapist using special equipment. The therapist may set up traction in the patient's home and visit regularly to ensure that the equipment is used and maintained properly.

Traction is used to:

- Create and maintain proper bone alignment after a fracture or other injury.
- Reduce or prevent joint stiffening and abnormal muscle shortening.
- Correct deformities.
- Relieve compression of vertebral joints.
- Reduce or relieve muscle spasms.

Although you will not be setting up or performing traction, you should know about its types and uses. This information will prepare you to answer basic questions from patients and family members.

Manual Traction

The physical therapist performs manual traction by using his hands to pull a patient's limb or head gently. Pulling stretches the muscles and separates the joints, allowing for greater motion and less stiffening. Manual traction is used with patients who have muscle spasms, stiffness, and arthritis.

Static Traction

To perform static traction, or weight traction, the therapist places a patient's limb, pelvis, or chin in a harness. The harness is then attached to weights through a pulley system. This type of traction is commonly used to relieve muscle spasms.

Skeletal Traction

Skeletal traction is performed in inpatient facilities on patients whose injuries require long traction time and heavy weights. During surgery, a surgeon inserts pins, wires, or tongs into bones. After surgery, the pins, wires, or tongs are attached to pulleys and weights to provide continuous traction.

Mechanical Traction

Mechanical traction uses a device that intermittently pulls and relaxes a prescribed body part, such as the neck. The therapist sets the time intervals between contractions and relaxations. Mechanical traction is used to promote relaxation.

► Mobility Aids

LO 54.7

Mobility aids (also called *mobility assistive devices*) are designed to improve patients' ability to ambulate, or move from one place to another. These include canes, walkers, crutches, and wheelchairs.

The appropriate aid depends on the patient's disability, muscle coordination, strength, and age. The patient may need a device temporarily—perhaps crutches after a sprain—or permanently—such as a wheelchair in the case of permanent paralysis.

Canes

Canes provide support and help patients maintain balance. They come in several styles, including standard, tripod, and quad-base (Figure 54-6), which are all lightweight, are made of wood or aluminum, and have a rubber tip or tips at the bottom. Canes are especially useful for patients with weaknesses

FIGURE 54-6 Shown here are three styles of canes: (a) standard, (b) tripod, and (c) quad-base.

on one side of the body (possibly due to a stroke), joint disability, or neuromuscular defects.

A standard cane is best for a patient who needs only a small amount of support. Its curved handle is convenient, allowing the patient to hang it from a pocket or a doorknob. When the patient uses a standard cane, however, the curved handle concentrates most of the patient's weight in one small area of the hand. To avoid stressing the hand in this way, some standard canes have a T-shaped handle, which distributes pressure on the hand more evenly. Tripod canes have three legs, and quad-base canes have four. The multiple legs create a wide base of support, making them more stable than a standard cane. Tripod and quad-base canes can stand alone, freeing up the patient's hands when she sits down. These canes are bulkier and more difficult to pick up and put down than a standard cane, however. Both styles have T-shaped handles.

After determining the most suitable cane for the patient, the physical therapist adjusts the cane's height. When the cane is the correct height, the patient's elbow is flexed at 20 to 25 degrees and the patient stands tall while using the cane (instead of leaning on it for support). The therapist makes sure the handle is the right size for the patient's hand and instructs the patient on how to use the cane. If directed, you may do the teaching or reinforce it, as discussed in Procedure 54-3 at the end of this chapter.

Walkers

A walker is a lightweight, easy-to-use aluminum frame that is open on one side and has four widely placed, adjustable, rubber-tipped legs that can be adjusted to various heights (Figure 54-7). Some models are designed to fold up for storage. To use a walker, the patient stands within the frame and leans on the upper bar, which has a handgrip on each side.

Typically, older patients who are too weak to walk unassisted or who have balance problems use a walker. The walker is designed to give these patients a sense of stability as they ambulate. In tight spaces or in areas with throw rugs, however, a walker may be difficult to manage. A patient who is too weak to pick up the walker may use a walker on wheels. Wheeled walkers have brakes for safety. Patients should never

FIGURE 54-7 A standard walker.

© SS36 PhotoDisc/Getty Images RF

slide a walker that does not have wheels because the movement could easily result in a fall.

A physical therapist selects a walker that suits the patient's abilities and height. A walker should reach the patient's hipbone. See Table 54-3 for more information about different types of walkers. Although the physical therapist usually trains the patient in the use of a walker, you may be asked to do this, or you may need to reinforce the information presented in Procedure 54-4 at the end of this chapter.

Crutches

Crutches allow a patient to walk without putting weight on the feet or legs by transferring that weight to the arms. Crutches are made of aluminum or wood. Aluminum crutches are lighter and usually more expensive than those made of wood. Pediatric crutches are available for children. The two basic types of crutches are axillary and Lofstrand®. Procedure 54-5, at the end of this chapter, provides the steps for teaching patients how to use crutches.

Axillary crutches reach from the ground to the armpit. Each crutch has a rubber tip on the bottom to prevent slipping. This type of crutch is designed for short-term use by patients with injuries such as a sprained ankle.

Lofstrand®, or Canadian, crutches reach from the ground to the forearm, and each one has a rubber tip on the bottom to prevent slipping. For additional support, this type has a handgrip extension attached at a 90-degree angle and a metal cuff that fits securely around the patient's forearm. Lofstrand® crutches are geared for long-term use by patients with disorders such as paraplegia (Figure 54-8).

Measuring the Patient for Crutches To prevent back pain and nerve injury to the armpits and palms, crutches must

TABLE 54-3 Types of Walkers			
Walker	Features	Advantages	Disadvantages
Standard	No wheels, adjustable legs	Very stable on flat surfaces; easier to use than crutches	Requires upper-body strength to use
Standard folding	No wheels, sides fold in	Easy to transport and store	Requires upper-body strength to use, requires pressing a tab to release and fold
Rolling	Front wheels	Requires less upper-body strength to use	Not as stable as a standard walker
Rolling with brakes	Front wheels and brakes	Disengages wheels when weight from upper body is applied	Not as stable as a standard walker
Three-wheel rolling with brakes	Bicycle-style hand brakes	Better maneuverability; folds for transport and storage	Requires better balance than other walkers
Reciprocal	Each side of walker moves alternately	Allows for more natural gait	Requires better balance and coordination than other walkers; catches on some floor surfaces

FIGURE 54-8 A child using Lofstrand® crutches.
© Royalty-Free/CORBIS

be measured to fit each patient. Axillary crutches that are too long can put pressure on nerves in the armpit, causing a condition called crutch palsy (muscle weakness in the forearm, wrist, and hand). They also can force the patient’s shoulders forward, causing strain on the back and making ambulation difficult. Crutches that are too short force the patient to bend forward during ambulation, causing back pain or imbalance, which can lead to falls.

Before a patient who uses crutches leaves the office, make sure the crutches fit properly and that the patient is comfortable walking with them. To confirm a correct fit, check for the following conditions (see Figure 54-9):

- The patient is wearing the type of shoes he will wear when walking.
- The patient is standing erect with feet slightly apart.
- The crutch tips are positioned 4 to 6 inches in front of the patient’s feet and 4 to 6 inches to the side of each foot.
- The axillary supports allow two to three finger-widths between supports and armpits. (Use wing nuts and bolts to adjust crutches.)

FIGURE 54-9 Use these guidelines when measuring a patient for crutches.
© Total Care Programming, Inc.

- The handgrips are positioned to create 30-degree flexion at the elbows. (Use wing nuts and bolts to adjust; use a goniometer to check flexion.)

Crutch Gaits To teach a patient how to stand and walk with crutches, you must learn the crutch gaits, or walks. First, show the patient the standing, or tripod, position. To do this, have the patient stand erect and look straight ahead. The patient should place the crutch tips 4 to 6 inches in front of

FIGURE 54-10 This is the correct beginning position for the patient's feet and crutches when you are teaching a patient to walk with crutches.

her feet and 4 to 6 inches away from the side of each foot. See Figure 54-10.

To determine the proper gait for a patient, you will make a preteaching assessment of the patient's muscle coordination and physical condition. In general, instruct a patient to use a slow gait in crowded areas or when feeling tired. The patient can use a faster gait in open places or when feeling more energetic. Using various gaits and speeds enables the patient to exercise different muscle groups and improve overall conditioning.

Four-Point Gait The four-point gait is a slow gait used only when a patient can bear weight on both legs. Because this gait has three points of contact with the ground at all times, it is stable and safe. It is especially useful for patients with leg muscle weakness, spasticity, or poor balance or coordination. To teach this gait, have the patient start in the tripod position. Then outline the following steps, as illustrated in Figure 54-11a:

1. Move the right crutch forward.
2. Move the left foot forward to the level of the left crutch.
3. Move the left crutch forward.
4. Move the right foot forward to level of the right crutch.

Three-Point Gait The three-point gait is used when a patient cannot bear weight on one leg but can bear full weight on the unaffected leg. This gait allows the patient's weight to be carried alternately by the crutches and by the unaffected leg. It is appropriate for amputees, patients with tissue or musculoskeletal trauma (such as a fractured or sprained leg), and those recovering from leg surgery. The patient must have good muscle coordination and arm strength, however. To teach this gait, have the patient start in the tripod position. Then give the patient the following instructions, as illustrated in Figure 54-11b:

1. Move both crutches and the affected leg forward.
2. Move the unaffected leg forward while weight is balanced on both crutches.

Two-Point Gait The two-point gait is faster than the four-point gait and is used by patients who can bear some weight on both feet and have good muscle coordination and balance. To teach this gait, have the patient start in the tripod position. Then outline the following steps, as illustrated in Figure 54-11c:

1. Move the left crutch and the right foot forward at the same time.
2. Move the right crutch and the left foot forward at the same time.

Step 4:

Move right foot forward.

Step 3:

Move left crutch forward.

Step 2:

Move left foot forward.

Step 1:

Move right crutch forward.

Starting position

(a)

(continued)

FIGURE 54-11 Crutch gaits include (a) a four-point gait, (b) a three-point gait, and (c) a two-point gait.

FIGURE 54-11 Crutch gaits include (a) a four-point gait, (b) a three-point gait, and (c) a two-point gait.

Swing Gaits Patients with severe disabilities, such as leg paralysis or deformity, may use one of two swing gaits: the swing-to gait or the swing-through gait (Figure 54-12). To teach the swing-to gait, have the patient start in the tripod position. Then outline the following steps:

1. Move both crutches forward at the same time.
2. Lift the body and swing to the crutches.

3. End with the tripod position again.

To teach the swing-through gait, have the patient start in the tripod position. Then review the following steps:

1. Move both crutches forward.
2. Move the body and swing past the crutches.

FIGURE 54-12 Patients with severe disabilities may walk with crutches using (a) the swing-to gait or (b) the swing-through gait.

Wheelchairs

Wheelchairs range from small, folding models to large, motorized ones. The physical therapist will select an appropriate wheelchair depending on the patient's disability and the length of time the wheelchair will be needed.

When patients come to the medical office in a wheelchair, the doctor may not be able to examine them adequately if they remain in the wheelchair. If this is the case, you will be responsible for transferring the patients from the wheelchair to the examining table and back to the wheelchair after the exam. To ensure their safety and yours, see the *Assisting with a General Physical Examination* chapter for more information about transferring patients from a wheelchair. Here are some reminders on preventing injury:

- Ask for help if the patient is weak, heavy, or unstable.
- Explain to the patient the steps of transfer you will use.
- Before starting the transfer, make sure the wheelchair is in the locked position and the patient is sitting at the front of the wheelchair seat.
- When you lift, use the large muscles in your thighs, which are stronger than your back muscles.

- When lifting, bend from the knees and keep your back straight.
- Count to 3 and enlist the patient's help on the count of 3.

► Referral to a Physical Therapist LO 54.8

If the doctor refers the patient to a physical therapist or other specialist, you may be asked to contact the specialist directly or to give the patient a written order and information about contacting the specialist. Keep a file with information about the therapists your office uses. In the file, note the forms and information each therapist requires. If you speak to the therapist, be sure to inform the doctor and to document the referral in the patient's chart. The therapist may be an independent practitioner or may be employed by a hospital, clinic, or home healthcare agency.

In addition to physical therapy, some patients may decide to try alternative therapies, such as acupuncture, chiropractic, or biofeedback training. These therapies are acknowledged by many healthcare professionals and often provide relief for people with chronic pain or other debilitating conditions.

PROCEDURE 54-1 Administering Cryotherapy

WORK // DOC

Procedure Goal: To reduce pain and swelling by safely and effectively administering cryotherapy

OSHA Guidelines:

Materials:

Patient chart/progress note, gloves, cold application materials required as ordered: ice bag, ice collar, chemical cold pack, washcloth or gauze squares, or ice

Method:

1. Double-check the physician's order. Be sure you know where to apply therapy and how long it should remain in place.
2. Identify the patient and explain the procedure and its purpose. Ask if the patient has any questions.
3. Have the patient undress and put on a gown, if required; provide privacy or assistance as needed.
4. Wash your hands and don gloves.
5. Position the patient comfortably and drape appropriately.
RATIONALE: *The patient should be able to relax during the therapy.*
6. Prepare the therapy as ordered.
 - Ice bag or collar
 - a. Prior to use, check the ice bag or collar for leaks.

- b. Fill the ice bag or collar two-thirds full with ice chips or small ice cubes. Compress the container to expel any air and then close it.

RATIONALE: *Ice will not conform to the patient if there is air in the bag.*

- c. Dry the bag or collar completely and cover it with a towel. This will absorb moisture and provide comfort.

- Chemical ice pack

- a. Check the pack for leaks.

RATIONALE: *To avoid the chemicals coming in contact with the patient.*

- b. Shake or squeeze the pack to activate the chemicals, or use a cold chemical pack taken from a refrigerator or freezer.

RATIONALE: *Pack will not be cold if it is not activated.*

- c. Cover the pack with a towel.

RATIONALE: *To keep the patient comfortable and avoid cold burn.*

- Cold compress

- a. Place the washcloth or gauze squares under a stream of running water.

- b. Wring them out.

- c. Rewet at frequent intervals.

7. Place the device on the patient's affected body part. If you are using a compress, place an ice bag on it, if desired, to keep it colder longer.

8. Ask the patient how the device feels.

RATIONALE: To prevent cold burn of the skin.

9. Explain that the cold is of great benefit, although it may be somewhat uncomfortable.

10. Leave the device in place for the length of time ordered by the physician. Periodically check the skin for color, feeling, and pain. If the area becomes excessively pale or blue, numb, or painful, remove the device and have the physician examine the area. For cold application using ice, limit application time to 20 minutes.

RATIONALE: To reduce the possibility of cold burn.

11. Remove the application and observe the area for reduced swelling, redness, and pain. If the patient has a dressing, replace it at this time.

12. Help the patient dress, if needed.

13. Remove equipment and supplies, properly discarding used disposable materials; sanitize, disinfect, and/or sterilize reusable equipment and materials as needed.

14. Remove the gloves and wash your hands.

15. Document the treatment and your observation in the patient's chart. If you teach the patient or the patient's family how to use the device, document your instructions.

PROCEDURE 54-2 Administering Thermotherapy

WORK // DOC

Procedure Goal: To administer thermotherapy safely and effectively

OSHA Guidelines:

Materials: Patient chart/progress note, gloves, towels, blanket, heat application materials required for order: chemical hot pack, heating pad, hot-water bottle, heat lamp, container and medication for hot soak, and container and gauze for hot compress

Method

1. Double-check the physician's order. Be sure you know where to apply therapy, the proper temperature for the application, and how long it should remain in place.
2. Identify the patient and explain the procedure and its purpose. Ask if the patient has any questions.
3. Have the patient undress and put on a gown, if required; provide privacy or assistance as needed.
4. Wash your hands and don gloves.
5. Position the patient comfortably and drape appropriately.

RATIONALE: The patient should be able to relax during the therapy.

6. If the patient has a dressing, check the dressing for blood and change as necessary. Alert the physician and ask if treatment should continue.

RATIONALE: If the wound is actively bleeding, heat application could cause increased bleeding.

7. Check the temperature by touch and look for the presence of adverse skin conditions (excessive redness, blistering, or irritation) on all applications before and during the treatment.

RATIONALE: To avoid patient burn injuries.

8. As necessary, reheat devices or solutions to provide therapeutic temperatures and then reapply them.

9. Prepare the therapy as ordered.

- Chemical hot pack

- a. Check the pack for leaks.

RATIONALE: To avoid the chemicals coming in contact with the patient.

- b. Activate the pack. (Check manufacturer's directions.)

RATIONALE: The pack will not get hot if it is not activated.

- c. Cover the pack with a towel.

- Heating pad

- a. Turn the heating pad on, selecting the appropriate temperature setting.

- b. Cover the pad with a towel or pillowcase.

- c. Make sure the patient's skin is dry and do not allow the patient to lie on top of the heating pad.

RATIONALE: To avoid burns.

- Hot-water bottle

- a. Fill the bottle one-half full with hot water of the correct temperature—usually 110°F to 115°F. Use a thermometer. The physician can provide information on the ideal water temperature that should be used, which will depend on the area being treated.

- b. Expel the air and close the bottle.

RATIONALE: The bottle should conform to the body part.

- c. Cover the bottle with a towel or pillowcase.

RATIONALE: To avoid burns.

- Heat lamp

- a. Place the lamp 2 to 4 feet away from the treatment area. (Check manufacturer's directions.)

- b. Follow the treatment time as ordered.

- Hot soak
 - a. Select a container of the appropriate size for the area to be treated.
 - b. Fill the container with hot water that is no more than 110°F. Use a thermometer. Add medication to the container if ordered.
 - Hot compress
 - a. Soak a washcloth or gauze in hot water. Wring it out.
 - b. Frequently rewarm the compress to maintain the temperature.
10. Place the device on the patient's affected body part, or place the affected body part in the container. If you are using a compress, place a hot-water bottle on top, if desired, to keep it warm longer.
 11. Ask the patient how the device feels. During any heat therapy, remember, dilated blood vessels cause heat loss from the skin and this heat loss may make the patient feel chilled. Be prepared to cover the patient with sheets or blankets.
 12. Leave the device in place for the length of time ordered by the physician. Periodically check the skin for redness, blistering, or irritation. If the area becomes excessively red or develops blisters, remove the patient from the heat source and have the physician examine the area.
 13. Remove the application and observe the area for inflammation and swelling. Replace the patient's dressing if necessary.
 14. Help the patient dress, if needed.
 15. Remove equipment and supplies, properly discarding used disposable materials, and sanitize, disinfect, and/or sterilize reusable equipment and materials as needed.
 16. Remove the gloves and wash your hands.
 17. Document the treatment and your observation in the patient's chart. If you teach the patient or the patient's family how to use the device, document your instructions.

PROCEDURE 54-3 Teaching a Patient How to Use a Cane

Procedure Goal: To teach a patient how to use a cane safely

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: A cane suited to the patient's needs

Method:

Standing from a Sitting Position

1. Instruct the patient to slide his buttocks to the edge of the chair.
2. Tell the patient to place his right foot slightly behind and inside the right front leg of the chair and his left foot slightly behind and inside the left front leg of the chair. (This provides him with a wide, stable stance.)
3. Instruct the patient to lean forward and use the armrests or seat of the chair to push upward. Caution the patient not to lean on the cane.
4. Have the patient position the cane for support on the uninjured or strong side of his body, as indicated.

Walking

5. Teach the patient to hold the cane on the uninjured or strong side of her body with the tip(s) of the cane 4 to 6 inches from the side and in front of her strong foot. Remind the patient to make sure the tip is flat on the ground.
- RATIONALE:** To reduce the risk of the patient falling.
6. Have the patient move the cane forward approximately 8 inches and then move her affected foot forward, parallel to the cane.
 7. Next, have the patient move her strong leg forward past the cane and her weak leg.
 8. Observe as the patient repeats this process.

Ascending Stairs

9. Instruct the patient to always start with his uninjured or strong leg when going up stairs.
10. Advise the patient to keep the cane on the uninjured or strong side of his body and to use the wall or rail, if available, for support on the weak side. If a rail is not available, the patient may need assistance for safety.
11. After the patient steps on the strong leg, instruct him to bring up his weak leg and then the cane.
12. Remind the patient not to rush.

Descending Stairs

13. Instruct the patient to always start with her weak leg when going down stairs.
14. Advise the patient to keep the cane on the uninjured or strong side of her body and to use the wall or rail, if available, for support on the weak side. If a rail is not available, the patient may need assistance for safety.
15. Have the patient use the uninjured or strong leg and wall or rail to support her body, put the cane on the next step, and bend the strong leg as she lowers the weak leg to the next step.
16. Instruct the patient to step down with the strong leg.

Walking on Snow or Ice

17. Suggest that the patient try a metal ice-gripping cane or a ski pole. These can be dug into the snow or ice to prevent slipping. Instruct the patient to avoid walking on ice unless absolutely necessary.

PROCEDURE 54-4 Teaching a Patient How to Use a Walker

Procedure Goal: To teach a patient how to use a walker safely

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: A walker suited to the patient's needs

Method:

Walking

1. Instruct the patient to step into the walker.
2. Tell the patient to place her hands on the handgrips on the sides of the walker.
3. Make sure the patient's feet are far enough apart so that she feels balanced.

RATIONALE: A wider base provides for better balance.

4. Instruct the patient to pick up the walker and move it forward about 6 inches.
5. Have the patient move one foot forward and then the other foot.
6. Instruct the patient to pick up the walker again and move it forward. If the patient is strong enough, explain that she

may advance the walker after moving each leg rather than waiting until she has moved both legs.

Sitting

7. Teach the patient to turn his back to the chair or bed.
8. Instruct the patient to take small, careful steps and to back up until he feels the chair or bed at the back of his legs.
9. Instruct the patient to keep the walker in front of himself, let go of the walker, and place both his hands on the arms or seat of the chair or on the bed.
10. Teach the patient to balance himself on his arms while lowering himself slowly to the chair or bed.
11. If the patient has an injured or affected leg, he should keep it forward while bending his unaffected leg and lowering his body to the chair or bed.

Ascending and Descending Stairs

12. If a patient needs to use a walker on stairs, refer him to a physical therapist for additional training.

PROCEDURE 54-5 Teaching a Patient How to Use Crutches

Procedure Goal: To teach a patient how to use crutches safely

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: A pair of crutches suited to the patient's needs

Method:

1. Verify the physician's order for the type of crutches and gait to be used.
2. Wash your hands, identify the patient, and explain the procedure.
3. Elderly patients or patients with muscle weakness should be taught muscle strength exercises for their arms.
4. Have the patient stand erect and look straight ahead.
5. Tell the patient to place the crutch tips 4 to 6 inches in front of and 4 to 6 inches to the side of each foot.
6. When instructing a patient to use an axillary crutch, make sure the patient has a 2-inch gap between the axilla and the axillary bar and that each elbow is flexed 25 to 30 degrees.

RATIONALE: To reduce the incidence of nerve injury to the axilla.

7. Teach the patient how to get up from a chair:
 - a. Instruct the patient to hold both crutches on his affected or weaker side.

FIGURE Procedure 54-5 Step 6 The patient's elbow should be flexed 25 to 30 degrees.

© McGraw-Hill Education

- b. Have the patient slide to the edge of the chair.
 - c. Tell the patient to push down on the arm or seat of the chair on his stronger side and use his strong leg to push up. If indicated, keep the affected leg forward.
 - d. Advise the patient to put the crutches under his arms and press down on the handgrips with his hands.
8. Teach the patient the required gait. Which gait the patient will use depends on the patient's muscle strength and coordination. It also depends on the type of crutches, the

FIGURE Procedure 54-5 Step 7c The patient should push up from his stronger side.

© McGraw-Hill Education

injury, and the patient's condition. Check the physician's orders, and see Figures 54-11 and 54-12 for examples.

9. Teach the patient how to ascend stairs:
 - a. Start the patient close to the bottom step and tell him to push down with his hands.
 - b. Instruct the patient to step up on the first step with his good foot.

FIGURE Procedure 54-5 Step 9b The patient should lead with his unaffected leg when ascending stairs.

© McGraw-Hill Education

- c. Tell the patient to lift the crutches to the same step and then lift his other foot. Advise the patient to keep his crutches with his affected limb.
 - d. Remind the patient to check his balance before he proceeds to the next step.
10. Teach the patient how to descend stairs:

- a. Have the patient start at the edge of the steps.
- b. Instruct the patient to bring his crutches and then the affected foot down first. Advise the patient to bend at the hips and knees to prevent leaning forward, which could cause him to fall.

FIGURE Procedure 54-5 Step 10b The patient should lead with the affected foot when descending stairs.

© McGraw-Hill Education

- c. Tell the patient to bring his unaffected foot to the same step.
 - d. Remind the patient to check his balance before he proceeds. In some cases, a handrail may be easier and can be used with both crutches in one hand.
11. Give the patient the following general information related to the use of crutches:
 - a. Do not lean on crutches.
 - b. Report to the physician any tingling or numbness in the arms, hands, or shoulders.
 - c. Support body weight with the hands.
 - d. Always stand erect to prevent muscle strain.
 - e. Look straight ahead when walking.
 - f. Generally, move the crutches not more than 6 inches at a time to maintain good balance.
 - g. Check the crutch tips regularly for wear; replace the tips as needed.
 - h. Check the crutch tips for wetness; dry the tips if they are wet.
 - i. Check all wing nuts and bolts for tightness.
 - j. Wear flat, well-fitting, nonskid shoes.
 - k. Remove throw rugs and other unsecured articles from traffic areas.
 - l. Report any unusual pain in the affected leg.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
54.1 Discuss the general principles of physical therapy.	Physical therapy is a medical specialty for the treatment of musculoskeletal, nervous, and cardiopulmonary disorders using a variety of treatments, including cold, heat, water, exercise, massage, and traction.
54.2 Relate various cold and heat therapies to their benefits and contraindications.	There are various types of cold and heat therapies, including dry and wet cold and heat applications. Cold and heat therapy promote healing and increase patient comfort. Contraindications to cold and heat therapies include circulation problems, pain, and hemorrhage.
54.3 Recall hydrotherapy methods.	Various types of hydrotherapy used to treat physical problems include whirlpools, contrast baths, and underwater exercises.
54.4 Name several methods of exercise therapy.	There are several methods of exercise therapy, including active mobility, passive mobility, aided mobility, and active resistance.
54.5 Describe the types of massage used in rehabilitation therapy.	The two major types of massage used in rehabilitation therapy are Swedish and neuromuscular. Swedish massage uses five basic strokes to manipulate soft tissues. Neuromuscular massage is applied to specific muscles and helps release tension and knots, relieve pain and release pressure on nerves, and increase blood flow. Trigger point therapy is commonly used during neuromuscular massage.
54.6 Compare different methods of traction.	The methods of traction used to treat physical problems include manual, static, skeletal, and mechanical.
54.7 Carry out the procedure for teaching a patient to use a cane, a walker, crutches, and a wheelchair.	The various mobility aids include canes, walkers, crutches, and wheelchairs. Specific instructions for each of these aids must be followed to reduce the possibility of patient injury during their use.
54.8 Model the steps you should take when referring a patient to a physical therapist.	You may be asked to contact the specialist directly or to give the patient a written order and information about contacting the specialist. Keep a file with information about the therapists your office uses, noting the forms and information each therapist requires.

C A S E S T U D Y C R I T I C A L T H I N K I N G

Recall Chris Matthews from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. What X-ray views did Dr. Whalen order?
2. What type of crutches would be best to give Chris?

3. What crutch gait will you teach Chris?
4. Dr. Whalen wants Chris to continue cryotherapy for the next 48 hours. What instructions will you give Chris and his mom?

EXAM PREPARATION QUESTIONS

- (LO 54.1) Which of the following is an example of inversion?
 - Flexing the foot
 - Pointing the foot upward
 - Turning the sole of the foot inward
 - Rotating the foot back and forth
 - Turning the sole of the foot downward
- (LO 54.1) Body position and alignment are known as
 - Posture
 - Gait
 - Range of motion
 - Flexion
 - Extension
- (LO 54.4) Which of the following is a type of exercise whereby the patient relaxes and contracts the muscles of a specific body part without moving the body part?
 - ROM
 - Passive mobility
 - Active resistance
 - Isometric
 - Aided mobility
- (LO 54.6) Another name for weight traction is
 - Static
 - Skeletal
 - Mechanical
 - Manual
 - Harness
- (LO 54.7) Which of the following crutch gaits is the best for someone with leg paralysis?
 - Two-point
 - Three-point
 - Swing-to
 - Four-point
 - Crutches are never used by people with leg paralysis
- (LO 54.2) Which of the following therapies causes blood vessels to constrict?
 - Neuromuscular massage
 - Thermotherapy
 - ROM
 - Active resistance exercise
 - Cryotherapy
- (LO 54.5) In Swedish massage, which of the following strokes is a percussive stroke?
 - Pétrissage
 - Effleurage
 - Vibration
 - Tapotement
 - Friction

SOFT SKILLS SUCCESS

Recall Chris Matthews from the case study at the beginning of the chapter. Dr. Whalen asks you to assist with wrapping Chris's ankle. She wants you to hold and stabilize his leg while she applies the elastic wrap. Chris's mom asks you if she will need any help rewrapping Chris's ankle. What should you tell Mrs. Matthews about taking care of Chris's bandage?

Nutrition and Health

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Mohammad Nassar	5/17/20XX	Animal dander
	Attending	MRN	Other Information
	Elizabeth H. Williams, MD	423-90-687	Current medications: Albuterol 4 mg bid

A 16-year-old male patient is brought to BWV Associates by his parents. As the medical assistant, you take his history and physical, noting that he has a past history of mild asthma. The patient mentions that he is avoiding food because he is being “careful not to eat too many calories” so that he can keep his weight down and have a chance to fight in the lightest

© David Sacks/Getty Images

weight class. He tells you he hopes to get a scholarship for wrestling so that he can attend college next fall. You note that his vital signs are blood pressure 100/60, height 5' 10", weight 131 lb, pulse rate 50. He appears dehydrated and exhibits signs of muscle weakness.

Keep Mohammad Nassar in mind as you study the chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 55, you will be able to:

- 55.1** Relate daily energy requirements to the role of calories.
- 55.2** Identify nutrients and their role in health.
- 55.3** Implement a plan for a nutritious, well-balanced diet and healthy lifestyle using the USDA's guidelines.
- 55.4** Describe methods used to assess a patient's nutritional status.
- 55.5** Explain reasons that a diet may be modified.
- 55.6** Identify types of patients who require special diets and the modifications required for each.
- 55.7** Describe the warning signs, symptoms, and treatment for eating disorders.
- 55.8** Educate patients about nutritional requirements.

KEY TERMS

- | | |
|-----------------------|----------------------|
| amino acid | dehydration |
| anabolism | fiber |
| anorexia nervosa | food exchange |
| antioxidant | gluten |
| behavior modification | lipid |
| bulimia nervosa | mineral |
| calorie | parenteral nutrition |
| catabolism | protein |
| celiac disease | saturated fat |
| cholesterol | unsaturated fat |
| complex carbohydrate | vitamin |

IV.C.1 Describe dietary nutrients including:

- (a) carbohydrates
- (b) fat
- (c) protein
- (d) minerals
- (e) electrolytes
- (f) vitamins
- (g) fiber
- (h) water

IV.C.2 Define the function of dietary supplements

IV.C.3 Identify the special dietary needs for:

- (a) weight control
- (b) diabetes
- (c) cardiovascular disease
- (d) hypertension
- (e) cancer
- (f) lactose sensitivity
- (g) gluten-free
- (h) food allergies

IV.P.1 Instruct a patient according to a patient's special dietary needs

IV.A.1 Show awareness of patient's concerns regarding a dietary change

X.P.3 Document patient care accurately in the medical record

2. Anatomy and Physiology

- b. Describe common diseases, symptoms, and etiologies as they apply to each system
- d. Apply a system of diet and nutrition
 - i. Explain the importance of diet and nutrition
 - ii. Educate patients regarding proper diet and nutrition guidelines
 - iii. Identify categories of patients that require special diets or diet modifications

9. Medical Office Clinical Procedures

- h. Teach self-examination, disease management and health promotion

► Introduction

Nutrition is the process of how the body takes in and utilizes food and other sources of nutrients. It is a five-part process that includes ingestion, digestion, absorption, metabolism, and elimination.

You need to know what effect nutrition has on health so that you can help patients meet their dietary requirements. Food is the body's source of nutrients, or substances the body needs to function properly. As you study this chapter, you will learn how the body uses nutrients and the importance of a well-planned diet to health. People need specific types of foods to stay healthy or to regain their health after illness or surgery. People with specific conditions also may need to follow special diets. As a medical assistant, you will work closely with the rest of the healthcare team to ensure that patients understand the role of diet in health and that they adhere to any diet prescribed by their licensed practitioner or dietitian.

► Daily Energy Requirements LO 55.1

The human body requires the nutrients in food for three major purposes:

- To provide energy
- To build, repair, and maintain body tissues
- To regulate body processes

A person's daily energy requirements depend on many factors. To understand the relationship of food to good health, you need to understand how the body uses food.

Metabolism

Food must be broken down before the body can use it. This process is an integral part of metabolism. Metabolism is the sum of all the cellular processes that build, maintain, and supply energy to your body tissues. During metabolism, body chemicals such as carbohydrates, proteins, and fats are built up and broken down, and heat and energy are produced.

Metabolism takes place in two phases. In **anabolism**, substances such as nutrients are changed into more complex substances and used to build body tissues. In **catabolism**, complex substances, including nutrients and body tissues, are broken down into simpler substances and converted into energy. The body uses this energy to maintain and repair itself. Of the energy people get from the food they eat, about 25% is directly used for bodily functions, and the rest becomes heat.

Each person's body requires a minimal amount of nutrients to carry on a basic level of metabolism to live. Each person's daily nutritional requirements vary with age, weight, percentage of body fat, activity level, state of health, and other variables. The body's metabolic rate, or speed of metabolism,

also can be affected by many factors, such as pregnancy, malnutrition, and disease.

Calories

The amount of energy a food produces in the body is measured in kilocalories. A kilocalorie, commonly called a **calorie**, is the amount of energy needed to raise the temperature of 1 kilogram of water by 1°C. Foods differ in the number of calories they contain. The more calories in a food, the more available energy it has. Calories also are used to measure the energy the body uses during all activities and metabolic processes.

As mentioned, people’s daily nutritional needs differ, depending on variables of age, weight, percentage of body fat, activity level, and state of health. If people eat an excess of calories—more than the body can use—the excess is stored as fat in the body. Conversely, lowering caloric intake causes the body to burn off stored fat for energy.

Depending on the food’s weight (in grams) or volume, each food has a value in calories. Therefore, you can count the number of calories a person consumes by monitoring food intake and adding up the calories in each food serving. You can use a food calorie counter, such as those often found in books or software applications, to look up caloric values. A calorie counter tells you, for instance, that 1 cup of cooked carrots contains 50 calories or that 1 cup of cooked corn kernels contains 130 calories. Calories also are listed on the labels of food packages. You can estimate the number of calories a person burns during certain activities by consulting a chart similar to Table 55-1.

TABLE 55-1 Calories Burned per Hour in Selected Activities	
Moderate Physical Activity	Approximate Calories/Hr for a 154-lb Person*
Hiking	370
Light gardening/yard work	330
Dancing	330
Golf (walking and carrying clubs)	330
Bicycling (<10 mph)	290
Walking (3.5 mph)	280
Weight lifting (general light workout)	180
Vigorous Physical Activity	Approximate Calories/Hr for a 154-lb Person*
Running/jogging (5 mph)	590
Bicycling (>10 mph)	590
Swimming (slow freestyle laps)	510
Aerobics	480
Walking (4.5 mph)	460
Heavy yard work (chopping wood)	440
Weight lifting (vigorous effort)	440
Basketball (vigorous)	440

*Calories burned per hour will be higher for people who weigh more than 154 lb (70 kg) and lower for people who weigh less.

Nutrients

LO 55.2

The body needs a variety of nutrients for energy, growth, repair, and basic processes. Seven basic food components provide these nutrients and work together to help keep the body healthy:

1. Proteins
2. Carbohydrates
3. Fiber
4. Lipids
5. Vitamins
6. Minerals
7. Water

As the body digests foods that contain these components, it breaks them down so that it can use them. Of the seven components, only proteins, carbohydrates, and lipids contain calories and provide the body with energy. The rest perform a variety of other essential functions.

Proteins

Protein is the most essential nutrient for building and repairing cells and tissues. Therefore, it is especially important for people to get enough protein during illness and healing. Other major functions of protein are to

- Help maintain the body’s water balance.
- Assist with antibody production and disease resistance.
- Help maintain body heat.

The optimal level of protein in a healthy person’s diet is 10% to 35% of total caloric intake. Eating a variety of lean proteins is best. A deficiency in protein leads to weight loss and fatigue, malnutrition, extremely dry skin, lowered resistance to infection, and interference with normal growth processes.

The body makes protein out of **amino acids**, which are natural organic compounds found in plant and animal foods. Besides being used to build and maintain tissue, protein can be broken down to produce energy, especially if other quick energy sources such as carbohydrates are low. Each gram of protein contains 4 calories. Excess protein is broken down by the body and contributes to fat stores.

Amino acids are found in animal sources such as meats, milk, fish, and eggs, as well as in plant sources such as soy, beans, legumes, nut butters, and some grains (such as wheat germ). Individuals do not need to eat animal products to get all the protein they need in their diet. See Figure 55-1.

Amino acids are classified into three groups:

- *Essential amino acids* cannot be made by the body and must be supplied by food. They do not all need to be eaten at one meal. The balance over the whole day is more important. There are nine essential amino acids.
- *Nonessential amino acids* are made by the body from essential amino acids or in the normal breakdown of proteins. There are four nonessential amino acids.
- *Conditional amino acids* are usually not essential, except in times of illness and stress. There are at least eight conditional amino acids.

(a)

(b)

FIGURE 55-1 Protein foods supply essential, nonessential, and conditional amino acids. (a) Individuals who eat animal products should select lean proteins and have seafood at least once a week. (b) Individuals who do not eat animal products can get protein from these foods.

(a) © McGraw-Hill Education/Jill Braaten, photographer; (b) © Royalty-Free/Corbis

Carbohydrates

Carbohydrates in food provide about two-thirds of a person's daily energy needs. Carbohydrates also provide heat and help metabolize fat. Each gram of carbohydrate contains 4 calories. The daily requirement for carbohydrates is 45% to 65% of total caloric intake. Carbohydrate deficiency leads to weight loss, protein loss, and fatigue.

There are two basic types of carbohydrates:

- *Simple carbohydrates* (sugars), found in fruits, some vegetables, milk, and table sugar
- *Complex carbohydrates*, found in grain foods, such as breads, pastas, cereals, and rice; in some fruits and

FIGURE 55-2 Healthful sources of carbohydrates are plentiful.

© Sian Invine/Getty Images

vegetables, such as potatoes, corn, broccoli, apples, and pears; and in legumes, such as peas, peanuts, and beans

Simple sugars are small molecules that consist of one or two sugar (saccharide) units. **Complex carbohydrates**, or polysaccharides, are long chains of sugar units. Starch is a type of complex carbohydrate that is a major source of energy from foods of plant origin. Fiber, another type of complex carbohydrate, is discussed in the next section.

Carbohydrates used for immediate fuel are converted to glucose, a simple sugar that cells use for energy. An excess of carbohydrates is either stored in the liver and muscle cells as glycogen (long chains of glucose units—the animal equivalent of starch) or converted into and stored as fat. After the body's carbohydrate reserves are depleted, it starts burning fat. Healthful, nutritive sources of carbohydrates include fruits and vegetables, whole-grain pasta and cereal, and potatoes (Figure 55-2). The American Dietetic Association suggests these sources of carbohydrates with an emphasis on complex carbohydrates such as vegetables, legumes, and whole-grain breads and cereals. Sugary foods such as sweet desserts, candy, and soft drinks also contain carbohydrates, but they are high in calories and low in nutritional value.

Fiber

Fiber is in a separate category, although it is a type of complex carbohydrate. Fiber does not supply energy or heat to the body. It is the tough, stringy part of vegetables and grains. Fiber is not absorbed by the body, but it serves these important digestive functions:

- Increasing and softening the bulk of the stool, thus promoting normal defecation
- Absorbing organic wastes and toxins in the body so that they can be expelled
- Decreasing the rate of carbohydrate breakdown and absorption

FIGURE 55-3 Dietary fiber serves many functions in the human body and is considered a basic food component.

© McGraw-Hill Education/Jill Braaten, photographer

Therapeutically, fiber can help treat and prevent constipation, hemorrhoids, diverticular disease, and irritable bowel syndrome. It is linked to reduced blood cholesterol levels, reduction of gallstone formation, control of diabetes, and reduction in the risk of certain types of cancer and other diseases. Too little fiber can result in an increased risk of colon cancer, hypercholesterolemia (high blood cholesterol), and increased blood glucose levels after eating. Too much fiber can cause constipation, diarrhea, and other gastrointestinal disorders and can impair mineral absorption.

The recommended amount of fiber for adults is 14 grams for every 1,000 calories you eat per day. So if you eat 2,000 calories each day, you should have 28 grams of fiber. Because fiber works in conjunction with other substances and nutrients, it is advisable to get dietary fiber from a variety of food sources (Figure 55-3). Adequate water intake is especially important for fiber to work properly.

Fiber can be classified as soluble or insoluble. Soluble fiber absorbs fluid and swells when eaten. It slows the absorption of food from the digestive tract, helps control the blood sugar level of diabetics, lowers blood cholesterol levels, and softens and increases the bulk of stools. Soluble fiber is found in foods such as oats, dry beans, barley, and some fruits and vegetables. Insoluble fiber promotes regular bowel movements by contributing to stool bulk. It is found in bran, whole-wheat bread, brown rice, and similar foods.

Lipids

Lipids in the diet include dietary fats and fat-related substances. Fats are a concentrated source of energy that the body can store in large amounts. Each gram of fat contains 9 calories (more than twice the calorie content of proteins and carbohydrates). About 95% of the lipids from plant and animal sources of food are fats. These simple lipids, or triglycerides, consist of glycerol (an alcohol) and three fatty acids. Chemical qualities of the fatty acids in a triglyceride determine the fat's characteristic flavor and texture. About 5% of dietary lipids are compound lipids such as cholesterol. Compound lipids are fat-related substances that are important components of cell membranes, nervous tissue, and some hormones.

Compound lipids are vital to the transport of all fat-like substances in the body. Lipids assist with important body functions and are essential to growth and metabolism. Among this nutrient's jobs are

- Providing a concentrated source of heat and energy.
- Transporting fat-soluble vitamins.
- Storing energy in the form of body fat, which insulates and protects the organs.
- Providing a feeling of satiety, or fullness, because it is digested more slowly than other nutrients.

A lipid deficiency can interfere with the body's absorption and utilization of vitamins and can cause fatigue and dry skin. However, an excess of lipids, particularly some dietary fats, can lead to increased levels of triglycerides and cholesterol in the blood and an increased risk of heart and artery disease and other diseases. It is recommended that adults obtain no more than 20% to 30% of their daily calories from fat sources. Cholesterol intake should be limited to 300 milligrams per day. People with heart disease and certain other diseases or risks may benefit from even lower levels of lipid intake.

Saturated and Unsaturated Fats The fats in food can be classified as either saturated or unsaturated (Figure 55-4). **Saturated fats** are derived primarily from animal sources and are usually solid at room temperature. They are found in meats and animal products such as butter, egg yolks, and whole milk. Coconut oil and palm oil are also saturated fats. Dietary Guidelines currently recommend consuming no more than 10% of total daily calories in the form of saturated fats. However, because research links high blood cholesterol levels with increased risk of heart disease, people who have heart disease or are already at risk for it should reduce their intake to no more than 5% or 6% of daily calories.

Unsaturated fats are usually liquid at room temperature. They include most vegetable oils. Unsaturated fats can be divided into two classes:

FIGURE 55-4 Foods that contain saturated fats include meat and butter. Most vegetable oils contain unsaturated fats.

© McGraw-Hill Education/Jill Braaten, photographer

- Polyunsaturated fats, such as corn, soya, safflower, and sunflower oils
- Monounsaturated fats, such as peanut, canola, and olive oils

The body needs essential fatty acids (primarily linoleic acid) to build and maintain body tissues. Because the body cannot produce these fatty acids, they must be supplied by food. Saturated fats in butter, egg yolks, and milk, as well as unsaturated fats in corn, canola, sunflower, and safflower oils, are good sources of essential fatty acids.

Trans Fats Also known as trans fatty acids, trans fats are a specific type of fat that is formed when hydrogen is added to vegetable oil through a process called *hydrogenation*, which turns liquid oils into solid fats. Trans fats can be found in vegetable shortenings, some margarines, crackers, candy, cookies, snack foods, fried foods, baked goods, and other processed foods. The US Food and Drug Administration (FDA) recommends that individuals consume as close to zero grams as possible on a daily basis. The FDA currently requires that the amount of trans fat be displayed on all food labels.

Cholesterol Cholesterol is a fat-related substance produced by the liver that also can be obtained through dietary sources. Only animal-based foods contain cholesterol. It is essential to health because it

- Serves as an integral part of cell membranes.
- Provides the structural basis for all steroid hormones and vitamin D.
- Is a component of bile, which aids in digestion.

Lipid Levels in the Blood Lipids, like other nutrients, are carried throughout the body in the bloodstream. When blood lipid levels become excessive, however, they pose certain risks. Licensed practitioners often order blood tests to determine the level of triglycerides and cholesterol in their patients' blood as a measure of overall health. High levels of cholesterol, especially if accompanied by high levels of triglycerides, may indicate an increased risk of heart disease, stroke, and peripheral vascular disease.

Lipids are not soluble in water; fats (or oils) and water do not mix. Because the fluid portion of blood is 90% water, lipids are encased in large molecules that are fat-soluble on the inside and water-soluble on the outside. These large molecules, called lipoproteins, carry lipids such as cholesterol and triglycerides through the bloodstream.

Low-density lipoproteins (LDL) and high-density lipoproteins (HDL) are the two main types of lipoproteins. Cholesterol in blood is identified as HDL or LDL, depending on which type of lipoprotein carries it. High levels of LDL cholesterol in blood are a primary risk factor for heart attacks. High levels of LDL cholesterol occur in people whose diets are high in saturated fats. HDL cholesterol, commonly referred to as good cholesterol, carries excess cholesterol away from arteries and back to the liver for breakdown and elimination. Patients often can reduce elevated cholesterol

TABLE 55-2 Saturated Fat and Cholesterol Content of Various Foods

Food	Saturated Fat (g)	Cholesterol (mg)
Cheddar cheese (1 oz)	6.0	30
Mozzarella, part skim (1 oz)	3.1	15
Whole milk (1 c)	5.1	33
Skim milk (1 c)	0.3	4
Butter (1 tbsp)	7.1	31
Mayonnaise (1 tbsp)	1.7	8
Tuna in oil (3 oz)	1.4	55
Tuna in water (3 oz)	0.3	48
Lean ground beef, broiled (3 oz)	6.2	74
Leg of lamb, roasted (3 oz)	5.6	78
Bacon (3 slices)	3.3	16
Chicken breast, roasted (3 oz)	0.9	73

Source: US Department of Agriculture.

levels by increasing exercise and intake of soluble fiber and decreasing the dietary intake of saturated fats. These measures tend to elevate the level of HDL cholesterol in the bloodstream and reduce the level of LDL cholesterol. Table 55-2 lists the saturated fat and cholesterol contents of various foods.

Vitamins

Vitamins are organic substances that are essential for normal body growth and maintenance and resistance to infection. Vitamins also help the body use other nutrients and assist in various body processes.

Most vitamins are absorbed directly through the digestive tract. Some vitamins are water-soluble and others are fat-soluble. Water-soluble vitamins, such as vitamin C and the B vitamins, are not stored by the body and therefore must be replaced every day. Fat-soluble vitamins, such as vitamins A, D, E, and K, are stored for longer periods.

The amounts of vitamins the body needs are relatively small; however, a vitamin deficiency through lack of ingestion or absorption can lead to disease. Some vitamins also can cause health problems if taken in excess. Toxic levels of vitamin A, for example, can produce effects ranging from headache to liver damage. Because the level of vitamin intake is so essential to health, the Food and Nutrition Board of the National Research Council has established recommended dietary allowances (RDAs) for vitamins. For detailed information on specific vitamins, see Table 55-3.

Eating a well-balanced, nutritious diet minimizes the likelihood of vitamin deficiency. Many manufactured foods are also vitamin-fortified. Even so, some people choose to augment their diets with vitamin supplements (Figure 55-5). A licensed practitioner may, in some instances, prescribe vitamin supplements for patients.

TABLE 55-3 Vitamins

Vitamin	Functions	Adult RDA*	Food Sources	Deficiencies and/or Toxicities
Vitamin A (retinol, provitamin, carotene)	Aids in night vision; cell growth and maintenance; normal reproductive function; health of skin, mucous membranes, and intestines	Males: 900 mcg retinol equivalents Females: 700 mcg retinol equivalents	Milk fat; butter; egg yolks; meat; fish liver oil; liver; green, yellow, and orange leafy vegetables; yellow and orange fruits	Deficiency: night blindness; dry, rough skin; risk of internal infection Toxicity: headache, vomiting, joint pain, hair loss, jaundice, liver damage
Vitamin B ₁ (thiamine)	Aids enzymes in breaking down and using carbohydrates; helps the nerves, muscles, and heart function efficiently	Males: 1.2 mg Females: 1.1 mg	Whole grains, brewer's yeast, organ meats, lean pork, beef, liver, legumes, seeds, nuts	Deficiency: beriberi with appetite loss, digestive problems, muscle weakness and deterioration, nervous disorders, heart failure
Vitamin B ₂ (riboflavin)	Aids enzymes in metabolism of fats and proteins	Males: 1.3 mg Females: 1.1 mg	Dairy products, organ meats, green leafy vegetables, enriched and fortified grain products	Deficiency: cracks at lip corners, irritations at nasal angles, inflammation of the tongue, seborrheic dermatitis, anemia
Vitamin B ₃ (niacin)	Aids enzymes in metabolism of carbohydrates and fats	Males: 16 mg Females: 14 mg	Meat, fish, poultry, enriched and fortified grain products	Deficiency: pellagra with dermatitis, diarrhea, inflammation of mucous membranes, dementia Toxicity: dilation of blood vessels; if sustained, abnormal liver function
Vitamin B ₆ (pyridoxine)	Aids enzymes in synthesis of amino acids	Males: 1.7 mg Females: 1.3–1.5 mg	Chicken, fish, pork, liver, kidney, some vegetables, grains, nuts, legumes	Deficiency: convulsions, dermatitis, anemia Toxicity: loss of muscle coordination, severe sensory neuropathy
Folate/folic acid (compounds)	Works with cobalamins in nucleic acid synthesis and metabolism of amino acids; maintains red blood cells	Males: 400 mcg Females: 400 mcg	Liver, yeast, legumes, green leafy vegetables, some fruits	Deficiency: glossitis, diarrhea, anemia, lethargy; folic acid deficiency during embryonic development may increase the risk of spina bifida
Vitamin B ₁₂ (cobalamins)	Works with folate in nucleic acid synthesis and metabolism of amino acids; coenzyme in metabolism of fatty acids	2.4 mcg	Seafood, meat, milk, eggs, cheese, brewer's yeast, blackstrap molasses	Deficiency: pernicious anemia, irreversible liver damage
Vitamin C (ascorbic acid)	Coenzyme involved in collagen production, capillary integrity, use of iron in hemoglobin, and synthesis of many hormones; improves absorption of iron; antioxidant	Males: 90 mg Females: 75 mg	Citrus fruits, mangoes, strawberries, green peppers, broccoli, potatoes, green leafy vegetables	Deficiency: scurvy with hemorrhages, loose teeth, poor wound healing Toxicity: stomachache, diarrhea
Vitamin D (calciferol)	Builds bones and teeth; helps maintain calcium-phosphorus balance in blood	5–15 mcg	Egg yolks, butter, liver, fortified milk, margarine, and prepared cereals	Deficiency: rickets in children, osteomalacia in adults Toxicity: excess blood calcium and phosphorus, calcium deposits in soft tissue, bone pain, irreversible kidney and cardiovascular damage
Vitamin E (group)	Aids in formation of red blood cells; maintains cell structure; intracellular antioxidant	15 mg	Vegetable oils, margarine, shortening, wheat germ, nuts, green leafy vegetables	Deficiency: damage to cells, hemolytic anemia
Vitamin K (compounds)	Aids in blood clotting and bone growth	Males: 120 mcg Females: 90 mcg	Green leafy vegetables, milk, dairy products, meat, eggs, cereals, fruits, vegetables	Deficiency: slow blood clotting; hemorrhagic disease in newborns

*RDAs may vary for different age groups.

Minerals

Minerals are natural, inorganic substances the body needs to help build and maintain body tissues and carry on life functions. Minerals are classified according to the relative amounts the body requires:

- Major minerals are those that the body needs in fairly large quantities, including calcium, magnesium, and phosphorus.
- Trace minerals are those that the body needs in tiny amounts, including iron, iodine, zinc, selenium, copper, fluoride, chromium, manganese, and molybdenum.

Most minerals are absorbed in the intestines, and any excess is eliminated. Calcium, iron, and iodine are the minerals in which people are most often deficient.

Minerals with Recommended Dietary Allowances

There are several minerals for which RDAs have been established. These minerals are calcium, iron, iodine, zinc, magnesium, phosphorus, and selenium.

Calcium Calcium builds healthy bones and teeth, aids in blood clotting, and helps nerves and muscles function properly. It is found in dairy products, green leafy vegetables, broccoli, legumes, and the soft bones of sardines and salmon (Figure 55-6).

Calcium deficiency can cause poor bone growth and tooth development in children, osteoporosis in adults,

FIGURE 55-6 These foods are excellent sources of calcium, a mineral that is necessary for strong bones and teeth.
© Mitch Hrdlicka/Getty Images RF

and poor blood clotting. The normal requirement is 800 to 1,200 milligrams per day.

Iron Iron, one of the most important nutrients, is essential for the production of red blood cells, which transport oxygen throughout the body. It is also a component of enzymes needed for energy production. Although iron is found in a wide variety of foods, it is the most frequently deficient nutrient in people's diets. Liver, meat, poultry, fish, egg yolks, fortified breads and cereals, dark green vegetables, and dried fruits are good dietary sources of iron (Figure 55-7), although less than 20% of it is usually absorbed.

Iron deficiency can cause anemia, a blood disorder that results in fatigue, weakness, and impaired mental abilities. At toxic levels, iron may increase the risk of coronary heart disease (CHD). The daily requirement is 10 to 15 milligrams.

FIGURE 55-7 Iron, a mineral that is needed in small amounts, is found in a wide variety of foods.
© McGraw-Hill Education/John Flounoury, photographer

Iodine Iodine plays a vital role in the activities of the thyroid hormones, which are involved in reproduction, growth, nerve and muscle function, and the production of new blood cells. Deficiency can cause an enlarged thyroid gland, known as *goiter*. Iodine can be obtained in seafood, iodized salt, and seaweed products. The daily requirement is 150 micrograms.

Zinc Zinc promotes normal growth and wound healing and participates in many cell activities that involve proteins, enzymes, and hormones. It is found in liver, lamb, beef, eggs, oysters, and whole-grain breads and cereals, although it is not always easily absorbed. Deficiency can result in growth retardation, impaired taste and smell, and reduced immune function. The daily requirement is 12 to 15 milligrams.

Magnesium Magnesium activates cell enzymes, helps metabolize proteins and carbohydrates, maintains the structural integrity of the heart and other muscles, and aids in muscle contraction. Good sources include green leafy vegetables, nuts, legumes, bananas, and whole-grain products. A deficiency may result from persistent vomiting or diarrhea, kidney disease, general malnutrition, alcoholism, and the use of certain medications. The daily requirement is 280 milligrams for women and 350 milligrams for men.

Phosphorus Phosphorus is involved in bone and tooth formation, chemical reactions in the body, and energy production. It is found in dairy foods, animal foods, fish, cereals, nuts, and legumes. A deficiency of phosphorus can cause gastrointestinal, blood cell, and other disorders. Toxicity is harmful as well, especially in people with kidney disorders. Too much phosphorus in the blood can decrease blood calcium levels and cause bone loss. The daily requirement is 800 milligrams for adults 25 and over.

Selenium Selenium works with vitamin E to aid metabolism, growth, and fertility. It is found in seafood, kidney, liver, meats, grain products, and seeds. A daily dietary intake of 55 micrograms for women and 70 micrograms for men is recommended.

Minerals with Estimated Safe and Adequate Dietary Intakes When data were sufficient to estimate a range of requirements—but insufficient for developing an RDA—the Food and Nutrition Board established a category of safe and adequate intakes for essential nutrients. The minerals in this category are copper, fluoride, chromium, manganese, and molybdenum.

Copper Copper interacts with iron to form hemoglobin and red blood cells. It can be obtained through a wide variety of foods, such as liver, seafood, nuts and seeds, and whole-grain products. Copper deficiency can cause anemia and central nervous system problems. The safe and adequate range of dietary copper for adults is 1.5 to 3.0 milligrams per day.

Fluoride Fluoride is another contributor to bone and tooth formation, and it protects against tooth decay. Many municipal water supplies are fluoridated, and the mineral is contained in saltwater fish, tea, and fluoridated toothpaste.

Fluoride deficiency may predispose people to cavities and osteoporosis. Excess fluoride can cause discoloration and pitting of the teeth as well as other conditions. The range of safe and adequate intake for adults is 1.5 to 4.0 milligrams per day.

Chromium Chromium is essential for the body to use glucose, the primary energy source for cells. Foods containing chromium include calf's liver, American cheese, and wheat germ. A range of intakes between 50 and 200 micrograms per day is considered safe and adequate for adults.

Manganese Manganese is part of several cell enzymes. It is also essential for bone formation and maintenance, insulin production, and nutrient metabolism. It is found in whole-grain products, fruits, vegetables, and tea. A daily dietary intake of 2 to 5 milligrams for adults is recommended.

Molybdenum Molybdenum helps in the metabolism of the mineral sulfur and the production of uric acid. The best sources are legumes, whole grains, milk, and organ meats such as liver and kidneys. The recommended range for dietary intake is 75 to 250 micrograms per day for adults.

Water

Water has no caloric value, but it contributes about 65% of body weight and is essential to the body's normal functioning. In general, water helps provide the body with other nutrients it needs and helps rid the body of what it does not need. Water has many functions, including:

- Helping to maintain the balance of all the fluids in the body.
- Lubricating the body's moving parts.
- Dissolving chemicals and nutrients.
- Aiding in digestion.
- Helping to transport nutrients and secretions throughout the body.
- Flushing out wastes.
- Regulating body temperature through perspiration.

The amount of water in the body directly affects the concentration and distribution of body fluids and all the functions related to them. The body maintains a careful balance between water consumed (in foods and beverages) and water lost (through urination, perspiration, and respiration). In a healthy fluid balance, water input equals water output. Measuring an ill person's level of water intake and output can help determine the best fluid replacement regimen to use.

People obtain most of their water from beverages such as tap water, milk, and fruit juices as well as coffee, tea, and soft drinks. On average, a person needs to drink six to eight glasses of water a day to maintain a healthy water balance. The daily need for water varies with size and age, the temperatures to which the person is exposed, the degree of physical exertion, and the water content of the foods the person eats. Someone who is eating mostly foods with a high water content, such as fruits and vegetables, can drink a little less water than someone who is eating mostly foods with a low water content.

If people get too little water or lose too much water through vomiting, diarrhea, burns, or perspiration, they become

dehydrated. Signs and symptoms of **dehydration** include dry lips and mucous membranes, weakness, lethargy, decreased urine output, and increased thirst. Severe dehydration can lead to hypovolemia, a reduction in the volume of blood in the body. Severe hypovolemia can result in inadequate blood pressure, which affects the functioning of the heart, central nervous system, and various organs—a condition known as hypovolemic shock. If dehydration progresses so that water is lost from body cells, death usually occurs within a few days. Patients should know whether they are to drink extra fluids to replace fluids lost in an illness or to help rid the body of waste.

Principal Electrolytes and Other Nutrients of Special Interest

The principal electrolytes are essential to normal body functioning. Other nutrients, such as antioxidants, also merit special mention.

Principal Electrolytes Although the principal electrolytes in the body—sodium, potassium, and chloride—are often excluded from lists of nutrients, they are essential dietary components. Electrolytes play an important role in maintaining body functions, such as normal heart rhythm.

Sodium Sodium (Na) maintains fluid and acid-base balances, assists in the transport of glucose, and maintains normal conditions inside and outside cells. Salt is the main dietary source of sodium, and high salt intakes are normally associated with a diet high in processed foods. Too much sodium can be associated with high blood pressure in salt-sensitive individuals. It is recommended that daily sodium intake be limited to 2.4 grams or less, although many Americans consume far more.

Potassium Potassium (K) is a crucial element in the maintenance of muscle contraction and fluid and electrolyte balance. It contributes to acid-base balance and the transmission of nerve impulses. Its role in fluid balance helps regulate blood pressure. Potassium occurs in unprocessed foods, particularly in fruits such as bananas, raisins, and oranges; many vegetables; and fresh meats (Figure 55-8). The minimum requirement is 1,600 to 2,000 milligrams per day.

Chloride Chloride (Cl) is essential in maintaining fluid and electrolyte balance, and it is a necessary component of hydrochloric acid, secreted into the stomach during digestion of food. Because dietary chloride comes almost entirely from sodium chloride, sources are essentially the same as those of sodium.

Antioxidants Antioxidants are chemical agents that fight certain cell-destroying chemical substances called *free radicals*. In fact, antioxidants may help ward off cancer and heart disease by neutralizing free radicals, which are by-products of normal metabolism that also may form as a result of exposure to various damaging factors such as cigarette smoke, alcohol, or X-rays. Antioxidants may be added to foods and cosmetics as preservatives. The nutrients beta-carotene, vitamin C, vitamin E, and selenium are natural antioxidants (Figure 55-9).

► Dietary Guidelines

LO 55.3

Dietary guidelines exist to help people get proper nutrition, reduce the occurrence of disease, and control their weight. These recommendations are designed to encourage healthy eating habits.

Dietary guidelines suggest the types and quantities of food that people should eat each day. They also may contain recommendations about which types of foods to limit and which types of foods to increase.

USDA Dietary Guidelines for Americans

The US Department of Agriculture (USDA) and the US Department of Health and Human Services updated their *Dietary Guidelines for Americans* in 2015. These guidelines encourage people to eat a balanced diet, limit consumption of less nutritious foods, increase physical activity, and make good nutritional decisions consistently.

FIGURE 55-9 Antioxidants are substances in food that may offer protection against certain chronic diseases. Foods rich in beta-carotene, vitamin C, vitamin E, and selenium contain antioxidants.

TABLE 55-4 USDA Dietary Guidelines Key Recommendations

Balancing calories to manage weight	- Promote healthy weight through improved eating and physical activity behaviors. - Control total calorie intake to manage body weight. For people who are overweight or obese, this will mean consuming fewer calories from foods and beverages. - Maintain appropriate calorie balance during each stage of life: childhood, adolescence, adulthood, pregnancy and breast-feeding, and older age.
Foods and food components to reduce	- Reduce daily sodium intake to less than 2,300 milligrams (mg). Further reduce intake to 1,500 mg among people who are 51 and older and those of any age who are African American or have hypertension, diabetes, or chronic kidney disease. - Consume less than 10% of calories from saturated fatty acids by replacing them with monounsaturated and polyunsaturated fatty acids. - Consume less than 300 mg per day of dietary cholesterol. - Keep trans fatty acid consumption as low as possible by limiting foods that contain synthetic sources of trans fats and by limiting other solid fats. - Reduce the intake of calories from solid fats and added sugars, but do not increase the use of low-calorie sweeteners to reduce sugar intake. - Limit the consumption of foods that contain refined grains, especially refined grain foods that contain solid fats, added sugars, and sodium. - If alcohol is consumed, it should be consumed in moderation (up to one drink per day for women and two drinks per day for men) and only by adults of legal drinking age.
Food and nutrients to increase (within calorie needs)	- Increase vegetable and fruit intake. - Eat a variety of vegetables, especially dark green, red and orange, beans, and peas. - Consume at least half of all grains as whole grains. - Increase intake of fat-free or low-fat milk and milk products. - Choose a variety of protein foods, which include seafood, lean meat and poultry, eggs, beans and peas, soy products, and unsalted nuts and seeds. - Increase the amount and variety of seafood consumed by choosing seafood in place of some meat and poultry. - Replace protein foods that are higher in solid fats with choices that are lower in solid fats and calories and/or are sources of oils. - Use oils to replace solid fats where possible. - Choose foods that provide more potassium, dietary fiber, calcium, and vitamin D, which are nutrients of concern in American diets.
Building healthy eating patterns	- Select an eating pattern that meets nutrient needs at an appropriate calorie level. - Monitor foods and beverages consumed, and their fit within a healthy eating pattern. - Follow food safety recommendations when preparing and eating foods.

Key Recommendations The USDA Dietary Guidelines recommend that you balance the food you eat with physical activity. They also recommend that you maintain or improve your weight to help reduce your chances of high blood pressure, heart disease, stroke, some types of cancer, and diabetes. Specific recommendations are included in Table 55-4. The latest information can be found at <http://www.health.gov/dietaryguidelines/>.

USDA Choose MyPlate Guidelines

MyPlate is an initiative based on the Dietary Guidelines for Americans discussed earlier. MyPlate is designed to remind Americans to eat healthfully and includes the following selected messages. See Figure 55-10.

Balancing Calories

- Enjoy your food, but eat less.
- Avoid oversized portions.

Foods to Increase

- Make half your plate fruits and vegetables.
- Make at least half your grains whole grains.
- Switch to fat-free or low-fat (1%) milk.

Foods to Reduce

- Compare sodium in foods such as soup, bread, and frozen meals—and choose foods with lower numbers.
- Drink water instead of sugary drinks.

You can educate patients to help them make better food choices by following the latest guidelines and using the SuperTracker and other tools found at <http://www.choosemyplate.gov>.

American Cancer Society Nutritional and Physical Activity Guidelines

The American Cancer Society updated its nutritional and physical activity guidelines in 2011 to aid in the prevention of cancer.

FIGURE 55-10 MyPlate is designed to remind Americans to make healthful food choices.
USDA

A summary of these guidelines is found in Table 55-5. For more information, visit its website at <http://www.cancer.org>.

▶ Assessing Nutritional Levels LO 55.4

Licensed practitioners assess a patient's nutritional status by analyzing age, health status, height, weight, type of body frame, body circumference, percentage of body fat, body mass

index, nutritional and exercise patterns, and energy needs. They accomplish this assessment through direct measurement as well as through questionnaires and interviews. During the analysis, practitioners take into account individual factors such as culture, beliefs, lifestyle, and education.

Body mass index (BMI) is a measure of body fat based on height and weight that applies to adult men and women. Body mass index calculators are available online. One example is at the National Heart, Lung, and Blood Institute's website. BMI is discussed in the *Vital Signs and Measurements* chapter.

To measure fat as a percentage of body weight, practitioners may perform a *skinfold test*, measuring the thickness of a fold of skin with a caliper (Figure 55-11). The test indicates the total percentage of fat because about 50% of body fat is just below the skin and the volume of fat below the skin is related to the volume of inner fat. A trained individual must perform this test, which must be precise to be reliable.

The optimal percentage of body fat differs between men and women. For males younger than age 50, it is 10% to 14%; age 50 and older, 12% to 19%. In females younger than age 50, it is 14% to 23%; age 50 and older, 16% to 25%. Aging usually changes the ratio a bit because some muscle tissue is replaced by fat, even if weight remains constant.

▶ Modified Diets LO 55.5

A person's diet has a significant effect on health, appearance, and recovery from disease. After a licensed practitioner or dietitian has established a patient's nutritional status, any necessary or beneficial dietary adjustments can be instituted. Dietary modification may be used alone or in combination with other therapies to prevent or treat illness.

TABLE 55-5 Summary of the American Cancer Society Guidelines on Nutrition and Physical Activity for Cancer Prevention

Recommendations for Individual Choices	
Achieve and maintain a healthy weight throughout life.	• Be as lean as possible throughout life without being underweight. • Avoid excess weight gain at all ages. For those who are overweight or obese, losing even a small amount of weight has health benefits and is a good place to start. • Get regular physical activity and limit intake of high-calorie foods and drinks as keys to help maintain a healthy weight.
Be a physically active.	• Adults: Get at least 150 minutes of moderate-intensity or 75 minutes of vigorous-intensity activity each week (or a combination of these), preferably spread throughout the week. • Children and teens: Get at least 1 hour of moderate- or vigorous-intensity activity each day, with vigorous activity on at least 3 days each week. • Limit sedentary behavior such as sitting, lying down, watching TV, and other forms of screen-based entertainment. • Doing some physical activity above usual activities, no matter what one's level of activity, can have many health benefits.
Eat a healthy diet, with an emphasis on plant foods.	• Choose foods and drinks in amounts that help you get to and maintain a healthy weight. • Limit how much processed meat and red meat you eat. • Eat at least 2½ cups of vegetables and fruits each day. • Choose whole grains instead of refined grain products.
If you drink alcohol, limit your intake.	• Drink no more than one drink per day for women or two per day for men.

FIGURE 55-11 To estimate an individual's body fat percentage, a professional uses a tool called a caliper to measure the thickness of a fold of skin at one or more points on the body.

Licensed practitioners work with dietitians to determine the best diet therapy to initiate for individual patients. Diet therapy is based on many factors, including particular foods and nutrients associated with different diseases or body states. Specific types of dietary modifications include changes in texture, nutrient level, frequency and timing of meals, and exclusions.

Texture

A patient may need changes in food consistency as a result of swallowing, chewing, or other gastrointestinal problems or to fulfill short-term needs that result from events such as laboratory tests or surgical procedures. The following special diets are based on texture:

- A *clear-liquid diet* consists solely of foods that you can see through, such as tea, broth, noncitrus juices, clear

carbonated beverages, popsicles, and gelatin. A full-liquid diet is less restrictive and includes strained cooked cereals, plain ice cream, sherbet, pudding, and strained soups.

- A *soft diet* includes foods that are easy to chew, swallow, and digest. Foods that patients cannot tolerate and those high in fiber are eliminated from this diet.
- All foods in a *puréed diet* are put through a strainer so that they are in the form of a semisolid. Puréed foods are easy to chew and swallow.
- A *high-fiber diet* contains large amounts of fiber (more than 40 grams) from sources such as fresh fruits, vegetables, and bran cereal. Licensed practitioners may prescribe this diet for patients with conditions such as diverticulosis and constipation. The diet increases the bulk of fecal matter and stimulates peristalsis (waves of alternating contraction and relaxation of the intestine that move contents through the intestine).

Nutrient Level

Licensed practitioners may make nutrient-level modifications in patients' diets before or after surgical or medical procedures or for patients who have specific conditions. Some of these types of diets are discussed in more detail in the next section. The following special diets are based on nutrient levels:

- Practitioners may prescribe *low-sodium diets* for patients who suffer from many disease conditions such as those affecting the cardiovascular or urinary system, liver, pancreas, and gallbladder, including edema and hypertension. The typical American diet contains 2 to 5 grams of sodium daily. Following are sodium-restricted dietary levels:
 - Mild restriction, 2 to 3 grams: reduce salt in cooking, add no salt at the table, and avoid processed foods
 - Moderate restriction, 1 gram per day: add no salt in cooking or at the table and limit high-sodium vegetables, meat, and milk
 - Severe restriction, 500 milligrams per day: greatly limit high-sodium vegetables, meat, milk, and eggs
- Practitioners recommend *low-cholesterol diets* for patients with high blood cholesterol levels. Such diets involve replacing saturated fats with unsaturated fats, using low-fat or nonfat cooking methods, and restricting fatty foods.
- Practitioners may prescribe *reduced-calorie diets* to promote weight loss in patients who are overweight.
- Practitioners may recommend *low-tyramine diets* for patients who have migraine headaches and patients who are taking certain antidepressant drugs. The compound tyramine is found in aged cheeses, red wine, beer, cream, chocolate, and yeast.
- Practitioners may order *high-calorie, high-protein diets* for patients who have infections, are recovering from burns or surgery, or have had weight loss caused by a severe illness. Food intake is increased to provide 3,000 to 5,000 calories per day. Protein usually accounts for the greatest caloric increase in these diets.
- Practitioners may prescribe *high-carbohydrate diets* for patients with kidney diseases and some cardiac conditions.

TABLE 55-6 Food Label Terms and Definitions

Term	Definition
Low calorie	Less than or equal to 40 calories per serving
Reduced calorie	At least 25% fewer calories per serving than the food it replaces
Cholesterol free	Less than or equal to 2 mg cholesterol per serving
Low cholesterol	Less than or equal to 20 mg cholesterol per serving
Reduced cholesterol	At least 25% less cholesterol per serving than the food it replaces
Low fat	Less than or equal to 3 g fat per serving
Reduced fat	At least 25% less fat per serving than the food it replaces
Sodium free	Less than or equal to 5 mg sodium per serving
Very low sodium	Less than or equal to 35 mg sodium per serving
Low sodium	Less than or equal to 140 mg sodium per serving
Reduced sodium	At least 25% less sodium per serving than the food it replaces

Source: US Department of Health and Human Services, Food and Drug Administration.

You can help patients who need to make nutrient-level modifications by teaching them how to read food labels. All packaged foods carry a Nutrition Facts label that contains information on the ingredients, major nutrients, and recommended amounts of key nutrients in daily diets. Procedure 55-1, at the end of this chapter, explains how to educate patients about reading food labels. You also can teach patients how to interpret the terms on food labels (Table 55-6). Understanding marketing terms simplifies the process of buying the right foods to meet special dietary needs.

Frequency and Timing of Meals

A patient's diet also may be modified by adjusting the standard three-meal pattern. The goal may be to eat six small meals rather than three large meals to minimize stress on organs affected by disease conditions—as in patients with an ulcer or a hiatal hernia. Six small meals also may be recommended to help regulate the blood sugar for patients with hypoglycemia, or low blood glucose. In other cases, meals may simply be timed to follow tests or therapeutic procedures.

Exclusion of Certain Foods

Licensed practitioners may order that specific foods be omitted from patients' diets for health reasons.

- In a *bland diet*, specific foods that cause irritation are eliminated, along with caffeine, alcohol, nicotine, aspirin, and some spices. A typical bland diet includes easily digested foods such as mashed potatoes and gelatins. Raw fruits and vegetables, whole-grain foods, and very hot or cold items are among foods to avoid. A practitioner may prescribe this type of diet for a patient with a peptic ulcer, for example. A patient with diverticulosis may be on a bland diet and

be restricted from eating nuts and seeds. In *diverticulosis* small pockets in the large intestine get blocked with food, causing pain and inflammation in the abdomen.

- *Exclusion diets* are prescribed for patients who have food intolerances. These diets eliminate foods that contain the offending substances but still provide the nutrients needed for good health. Intolerance to lactose, the sugar in milk, is fairly common. Intolerance to the amino acid phenylalanine—a condition present at birth—is fairly rare but very serious. Infants born in hospitals in the United States are tested for this intolerance because if these infants were to receive a standard diet, they would develop severe mental disability. People with this condition, known as phenylketonuria (PKU), must be vigilant about checking labels on prepared foods as well as knowledgeable about the phenylalanine content of fresh foods.

Intolerance to **gluten**, a protein substance found naturally in wheat, barley, and rye, can result from several conditions, including celiac disease and non-celiac gluten sensitivity (NCGS). Gluten consumption in non-celiac gluten-sensitive patients can cause intestinal symptoms such as bloating and nausea. Unlike with NCGS, **celiac disease** is an autoimmune reaction to gluten. After eating gluten, the patient with celiac disease experiences damage to the small intestine, which causes reduction in the absorption of nutrients from foods. Patients with gluten intolerance should eat only gluten-free foods. The FDA has established specific guidelines for labeling foods “gluten-free” so that gluten-intolerant individuals can select foods with more confidence that they will not contain gluten.

► Patients with Specific Nutritional Needs

LO 55.6

A variety of conditions require special diets or nutrients. In situations such as those that follow, you may need to educate patients about their diets and answer their questions. You may need to provide encouragement and emotional support and teach patients' caregivers how to perform physical tasks, such as holding utensils for patients during meals.

Patients with Allergies

Some patients have food allergies. Usually, specific foods must be eliminated from or restricted in an allergic patient's diet. Procedure 55-2, at the end of this chapter, provides information on discussing with the patient potential dangers of common foods and reactions to those foods.

Some of the most common food allergens are wheat, milk, eggs, shellfish, peanuts, and chocolate. The licensed practitioner may confirm an allergy by eliminating and then reintroducing the patient's suspect foods one by one. The patient's allergy may decrease over time through systematic desensitization by means of allergy shots and other regimens.

If a food that is being eliminated or restricted was a primary source of nutrients for the patient, then the practitioner must adjust the diet to include another source of those nutrients. For example, for a baby who is allergic to milk, the licensed practitioner may recommend a milk-substitute formula.

Regardless of how careful they try to be, patients with food allergies may occasionally ingest a food to which they are allergic. It is a good idea to prepare the patient by explaining how to treat an allergic reaction. For mild reactions, an over-the-counter antihistamine such as Benadryl® may reduce the symptoms. For severe reactions, the patient should be transported to the nearest emergency room or urgent care center, where a licensed practitioner will order a shot of epinephrine. For some patients with severe allergies, the licensed practitioner may prescribe epinephrine in the form of an EpiPen® that the patient can self-administer as a shot immediately when an allergic reaction begins. Researchers are currently experimenting with desensitization methods that may help reduce the severity of a person's reaction to food allergens.

Patients with Anemia

Iron deficiency anemia, the most common type of anemia, is usually caused by chronic blood loss, a lack of iron in the diet, impaired intestinal absorption of iron, or an increased need for iron, as in pregnancy. A patient may need to take iron supplements and ingest more dietary iron as part of the treatment for this disorder. Foods high in iron include liver, egg yolks, dark green vegetables, beans, some dried fruits, and fortified breads and cereals.

Patients with Cancer

Many patients being treated for cancer undergo weight loss resulting both from the cancer and from treatments involving radiation or chemotherapy. To help their bodies fight off the cancer, it is especially important that they get enough protein because protein is needed to regenerate cells to replace the cells destroyed by the cancer and cancer treatments. These patients also may need to increase their intake of B vitamins and vitamins A, C, D, and E to support tissue growth and repair and promote efficient metabolism and use of all nutrients in the diet.

Encourage patients with cancer to follow the diet the licensed practitioner sets for them. Patients may find this difficult because cancer often produces loss of appetite. They also may experience nausea and vomiting. Educate patients and their caregivers about ways to make food more appealing and easier to digest. Consuming small meals at frequent intervals may help. Patients also may follow a liquid diet. Bringing food to room temperature or chilling it slightly may reduce food odors that can trigger nausea. In some cases, especially during cancer treatment, the practitioner will prescribe medications to reduce the nausea and thus increase the patient's appetite.

Patients with Diabetes

A special diet is one of the foundations of treatment for diabetes. Dietary guidelines for patients with diabetes must not only provide them with adequate nutrition but also keep their blood sugar level under control and interact appropriately with medication.

The diet a practitioner or dietitian prescribes for someone with diabetes includes specific numbers of calories, meals per day, amount of carbohydrates, and amounts of other nutrients. As a way to simplify the diet, a system of **food exchanges** is used. All food exchanges in a particular food category provide the same amounts of protein, fat, and carbohydrates.

The list of exchanges is divided into seven categories—nonstarchy vegetables, fruits, starches, meats/meat alternatives, fats, milk, and sweets—and indicates how large a portion of each food in a category is equal to one “exchange” of food in that category. This information tells patients what portions of specific foods are interchangeable and whether they are eating the correct amounts of those foods. The list includes a variety of foods from which patients make their selections. It is important that patients with diabetes not skip a meal because skipping meals disturbs the balance of blood sugar and metabolism. Table 55-7 provides example food exchanges recommended for diabetics. These lists also can be obtained from a registered dietitian or the American Diabetes Association.

Patients with diabetes who are dependent on insulin should eat regular meals at consistent times. Skipping or delaying meals can result in hypoglycemia or an insulin reaction. The healthcare team specifies the proportion of carbohydrates and calories in meals, depending on the type of insulin each patient uses and the timing of injections.

Fiber is also important for patients who have diabetes. Fiber can sometimes prevent a sharp rise in blood glucose after a meal and may reduce the amount of insulin needed. It is therefore recommended that people with diabetes gradually increase their fiber intake until it is at about 45 grams per day.

Patients with Heart Disease

Coronary heart disease that is caused by atherosclerosis usually results from hyperlipidemia, or an excess of lipids in the bloodstream. Left untreated, this condition can lead to angina, heart attack, or stroke.

Patients can significantly lower their risk by reducing their blood cholesterol levels and losing weight if they are overweight. Patients who have coronary heart disease usually must reduce their consumption of fats to a level that provides less than 30% of their total caloric intake. Saturated fats should provide less than 10% of their caloric intake. Patients who have had a heart attack or are at increased risk for a heart attack are also encouraged to increase their consumption of soluble fiber.

As a medical assistant, your role with these patients is to encourage them to follow the nutritional regimen prescribed by the licensed practitioner.

Patients with Hypertension

Hypertension (high blood pressure) is a condition that affects more than 20% of American adults. Nutritional therapy for patients with hypertension involves:

- Restricting sodium intake to 2 to 3 grams per day, especially in salt-sensitive individuals.
- Increasing potassium intake through consumption of fresh fruits and vegetables, especially when taking certain medications.
- Ensuring adequate calcium intake to meet an RDA of 800 milligrams.
- Eliminating or reducing alcohol use.
- Decreasing total fat intake and obtaining no more than 10% of calories from saturated fats.

TABLE 55-7 Diabetic Food Exchange Table

Food Exchange	US Unit	Comments	
Starches			
15 g Carb, 3 g Protein, 1 g Fat		- Most starches are a good source of B vitamins. - Choose whole-grain foods such as 100% whole-wheat bread and flour, brown rice, and tortillas for nutrients and fiber. - Combine beans (starch and meat) with grains (starch) for their complementary proteins and fiber. - Combine grains (starch) with milk (milk exchange) or cheese (meat exchange) to complement proteins. - Add 1 fat exchange for starchy foods prepared with fat.	
- English muffin - Graham crackers (2½-inch squares) - Bagel, large (4 ounces) - Bread, pumpernickel, rye, white, whole-grain - Bread, reduced calorie - Cereal: bran, oats, spoon-size shredded wheat, frosted cereals - Cereal: unsweetened - Grits, cooked - Tabbouleh, prepared - Pasta, cooked - Wild rice, cooked - Corn - Popcorn, popped - Potato (large, baked with skin) - Potato, mashed - Sweet potato - Squash, acorn, butternut	½ 3 ¼ (1 oz) 1 slice (1 oz) 2 slices (1½ oz) ½ cup ¾ cup ½ cup ½ cup ⅓ cup ½ cup ½ cup 3 cups ¼ (3 oz) ½ cup ½ cup (4 oz) 1 cup		
Add 1 meat exchange for the following starches:			
- Baked beans - Beans, cooked: black, garbanzo, kidney, lima, pinto, navy, white - Peas, cooked: black-eyed, green - Refried beans, canned	⅓ cup ½ cup ½ cup ½ cup		
Vegetables (3–5 exchanges)			
5 g Carb, 2 g Protein			Choose more dark green leafy and deep yellow vegetables such as spinach, broccoli, carrots, and peppers.
- Raw vegetables - Cooked vegetables	1 cup ½ cup		
Fruit (2–4 exchanges)			
15 g Carb			- Choose whole fruits for fiber. - Choose citrus fruits such as oranges, grapefruits, or tangerines.
Fresh fruit:			
- Apple, small (2 inches across) - Berries: blackberries, blueberries - Grapefruit, large - Mango, cubed - Orange, small - Strawberries	1 (4 oz) ¾ cup ½ ½ cup 1 (6 oz) ¼ cup (13½ oz)		
Dried fruit:			
- Apple - Prunes - Raisins	4 rings 3 2tbsp		

(Continued)

TABLE 55-7 Diabetic Food Exchange Table

Food Exchange	US Unit	Comments
<i>Canned fruit, unsweetened:</i>		
• Applesauce, apricots, cherries, peaches, pears, pineapple, plums	½ cup	
• Grapefruit	¾ cup	
• Mandarin oranges	¾ cup	
<i>Fruit juice, unsweetened:</i>		
• Apple, grapefruit, orange, pineapple	½ cup (4 fl oz)	
<i>Meat & Substitutes (5–7 exchanges)</i>		
7 g Protein, 0–13 g Fat		- Choose leaner meats such as chicken, fish, and lean cuts of meat; add fat exchange for higher-fat meats and substitutes. - Remove skin from poultry. - Limit frying or adding fat. - Have 2 servings of fish per week for omega-3 fatty acid.
• Beef	1 oz	
• Cheese	1 oz	
• Cottage cheese	¼ cup	
• Egg whites	2	
• Egg substitutes	¼ cup	
• Fish, fresh or frozen	1 oz	
• Pork	1 oz	
• Bacon	2 slices	
• Poultry	1 oz	
• Peanut butter	1 tbsp	
• Tofu	½ cup	
<i>Milk (2–3 exchanges)</i>		
12 g Carb, 8 g Protein, 0–8 g Fat		Choose lower-fat milks; add fat exchange for higher-fat milk.
• Milk	1 cup	
• Soy milk	1 cup	
• Rice drink, low-fat, flavored	1 cup (8 fl oz)	
• Yogurt, low-fat with fruit	⅔ cup (6 oz)	
<i>Fat (use sparingly)</i>		
5 g Fat		- Eat less fat. - Eat less saturated fat, such as animal fat found in fattier meat, cheese, and butter; also eat less hydrogenated fat. - Check Nutrition Facts on food labels; 5 g Fat 5 1 Fat exchange.
• Almonds	6	
• Coconut, shredded	2 tbsp	
• Oil: canola, olive, peanut, corn, safflower, soybean, sunflower	1 tsp	
• Mayonnaise	1 tsp (1 tbsp if reduced-fat)	
• Cream cheese	1 tbsp (1½ tbsp if reduced-fat)	
• Salad dressing	1 tbsp (2 tbsp if reduced-fat)	
• Peanuts	10	
• Avocado	2 tbsp (1 oz)	
• Butter or margarine	1 tsp

Patients with Lactose Sensitivity

Lactose is the sugar contained in human and animal milk. It must be broken down in the body by the enzyme lactase to enable the body to digest dairy products. In people from some parts of the world, lactase is present in the body until age 3 or 4, after which it all but disappears. As a result, after early childhood many people have trouble digesting foods that contain lactose and eliminate these foods from their diets. People who are especially sensitive to dietary lactose are often referred to as *lactose intolerant*.

Chemical preparations can help a person digest lactose. Those preparations may be added to certain foods, such as ice cream, for lactose-sensitive people. If people with a lactose sensitivity choose to avoid dairy products, they need to be sure to obtain protein and calcium from other sources.

Patients Who Are Overweight

More than two-thirds of American adults are overweight or obese. Seventeen percent of children age 2 to 19 are obese. Overweight patients weigh 10% to 20% more than is recommended for their height and gender. Patients who are more than 20% overweight are considered obese. Morbid obesity is when someone is more than 100 pounds overweight. Obesity can lead to medical complications such as elevated blood cholesterol levels, hypertension, diabetes, joint problems, respiratory problems, and heart disease. See *Educating the Patient* to learn more about how to help patients avoid these complications.

Approaches to Weight Loss Weight reduction may be approached with dietary modification alone, but an exercise

program is usually included. Behavior modification is also a common element of weight-loss programs. In a weight-loss program, foods should be proportioned in accordance with dietary guidelines and the diet should be appealing and enjoyable. The goal is to have the patient decrease daily caloric intake and increase physical activity at an appropriate rate while remaining comfortable and healthy.

Weight loss will not occur unless patients expend more energy than they consume. Calculators are available online and in smartphone apps that help individuals determine how much they can eat and how much exercise will result in weight loss. Foods that are high in nutrients but low in calories are desirable.

One example of a healthy diet is the Dietary Approaches to Stop Hypertension (DASH) diet. Originally created to help reduce hypertension, the DASH diet is now considered one of the healthiest diets for weight loss as well. It emphasizes “real foods”—foods that do not contain additives. It is a low-sodium, high-fiber diet that emphasizes vegetables and fruits and includes plenty of sources of important minerals and vitamins. Versions are available for both vegetarians and nonvegetarians. Credible organizations, including the American Heart Association, the Mayo Clinic, and the National Heart, Lung, and Blood Institute, have endorsed this method.

The **behavior modification** facet of weight loss includes methods such as keeping a food diary to pinpoint overeating patterns, controlling the stimuli associated with overeating, and providing rewards for successful behavior. Weight-loss behaviors are important to maintain for a lifetime.

You can help overweight patients in their weight-loss efforts by teaching them to

- Eat slowly, because the message that the stomach is full takes 20 minutes to register with the brain.
- Eat five or six small meals daily.
- Be patient—reliable weight loss occurs over time, not immediately.

EDUCATING THE PATIENT

Preventing Obesity

Most organizations recommend the same general steps for preventing obesity: make healthy food and drink choices, get a moderate amount of exercise, and control calories. Many patients have heard this advice many times and may tend to tune it out. To prevent this, try to give patients some new information and tips they may not have heard before.

One method that patients may not be aware of is the need to avoid distractions while eating. Eating in front of the television or while reading a book or newspaper may seem relaxing, but when attention is distracted from eating, people tend to continue to eat even though they may feel full. The body signals when you have had enough to eat, but if your attention is on a good movie or the action in a book, you may not even notice that you are full.

A related tip is to concentrate on the food. By focusing all of the senses on the food being eaten, a person can enjoy and savor the food. This, in turn, can result in being satisfied with a smaller portion, which reduces calorie intake.

Finally, explain to patients the importance of getting sufficient sleep. Although the amount of sleep needed varies with the individual, research has provided evidence that getting a good night's sleep can actually help keep a person at a healthier weight. In general, adults need 7 to 8 hours of sleep per night. The number of hours per night increases as a person's age decreases; adolescents may need up to 9.25 hours per night, while toddlers may need up to 14 hours per night.

Motivation and Education Patients who are trying to lose weight may have trouble with motivation. You may be able to introduce the patient to low-calorie or low-fat recipes, for instance, and positively reinforce the patient's efforts by complimenting small, gradual successes.

Tell patients that fad weight-loss methods can lead to vitamin, mineral, and protein deficiency; serious medical disorders; and even death. Use the following criteria to identify fad diets:

- They promise ease and comfort in weight loss.
- They include only a few foods, such as grapefruit or low-protein foods.
- They require the purchase of a secret ingredient or pill.
- They are often published in a book or magazine.

Truly effective weight-loss regimens usually possess the following qualities:

- They include a variety of foods that contain adequate nutrients.
- They include an activity component.
- They may be safely followed over a long period of time.

An effective program is one in which the patient is able to lose weight (including fat) gradually and constantly, with some plateaus, and then maintain the loss indefinitely afterward. You can help patients with the challenge of maintaining their weight loss by recommending a reputable weight-loss group or support group that will help them make the necessary lifestyle changes and remain motivated.

Pediatric Patients

During the first year of life, an infant experiences the most rapid period of growth and development that occurs during the lifespan. Breast milk is the best food for an infant up to 6 months of age. It contains the right amount of fat, sugar, water, and protein for an infant's growth and development. Breast-feeding saves time and money and helps the mother recover as well as reduces the risk of breast and ovarian cancers. If breast-feeding is not an option, infant formula is recommended by the licensed practitioner. Regular, full-fat cow's milk should not be given to a child until after his or her first birthday.

Solid foods are introduced gradually starting at age 4 to 6 months. Infants should be able to hold their head up while sitting, open their mouth, swallow, and have an interest in food. The following are some basic guidelines for introducing foods to infants and toddlers:

- About 4 to 6 months: iron-fortified, single-grain baby cereal; strained/puréed vegetables and fruit
- 6 to 9 months: strained meats/poultry; mixtures of strained vegetables and fruits; chunky, soft prepared baby foods; egg yolk; yogurt; cottage cheese

- 9 to 12 months: soft, finely chopped foods; soft combination foods such as casseroles; macaroni and cheese; spaghetti; cheese; beans
- Over 12 months: toddler foods; family foods; fiber foods; whole cow's milk

Additional detailed information is available about the nutritional requirements for infants and children at the US Department of Agriculture website, <http://www.usda.gov>. Parents should be educated about these guidelines during their visits to the pediatrician's office.

The pace of growth is steadier and slower during childhood, with growth spurts throughout. Nutritional needs change to reflect growth, maturation, and increasing activity levels. Vitamin D and calcium are critical to tooth and bone formation, and fluoride strengthens teeth. Hunger regulates food intake in young children, but forcing children to eat can promote eating habits that lead to obesity.

Patients Who Are Pregnant or Lactating

Nutrition is especially important during pregnancy, when it provides for the normal growth and health of the baby as well as the health of the pregnant woman. Licensed practitioners recommend that pregnant women gain a certain amount of weight during each trimester of pregnancy, with a total weight gain of about 25 to 35 pounds. The rate of weight gain should be 2 to 5 pounds in the first trimester and about 1 pound per week after that. Gaining too little or too much weight during pregnancy can result in serious complications. See Figure 55-12.

Here are some nutritional suggestions for pregnant women:

- An additional 10 to 15 grams of protein a day in the form of meat, poultry, fish, eggs, and dairy products
- 1,200 milligrams of calcium a day, preferably in the form of low-fat dairy products such as skim milk

FIGURE 55-12 Pregnant patients should follow special nutritional guidelines to help ensure a healthy baby and mother.

© Brand X Pictures/Jupiterimages RF

- 30 milligrams of iron a day through meat, liver, egg yolks, grains, leafy vegetables, nuts, dried fruits, legumes, and supplements (it is difficult to meet the daily need with food alone)
- Folic acid intake of 400 micrograms a day through leafy vegetables, yeast, and liver as well as supplements
- Adequate fiber intake to prevent the constipation that often accompanies pregnancy

Breast-feeding has specific nutritional and dietary requirements as well, because breast milk is nutrient-rich and the body requires considerable energy and nutrients to produce it. The infant depends on this milk for the extensive growth that takes place during the first months of life. Lactating women need to consume an additional 500 calories and an additional 12 to 19 grams of protein per day as well as 260 to 280 micrograms of folic acid and 1,200 milligrams of calcium.

Patients Requiring Supplements and/or Parenteral Nutrition

When a patient has a loss or lack of appetite or cannot tolerate a normal meal, the licensed practitioner may prescribe a specially formulated food supplement that provides protein, carbohydrates, fat, vitamins, and minerals. A patient who is chronically ill, underweight, or anemic or who has just undergone surgery may take supplements orally or through a tube to the stomach or small intestine. If the supplement is being taken orally, encourage the patient to follow the prescribed directions.

When patients cannot tolerate receiving supplements enterally (by way of the digestive tract), they may be fed parenterally. **Parenteral nutrition** is provided to patients as specially prepared nutrients injected directly into their veins rather than given by mouth. Because a parenteral feeding bypasses the digestive system, the nutrients it contains must already be in a form the body can use as they enter the blood.

Patients Undergoing Drug Therapy

Drugs may change a patient's nutritional status and needs. Long-term drug therapy and the need to take multiple medications make close nutritional monitoring a high priority.

Drug therapy can cause a change in food intake, a change in the body's absorption of a nutrient, or both. Likewise, foods can interfere with the metabolism and action of a drug. For example, laxatives and certain other types of drugs may suppress the appetite. Antihistamines, alcohol, insulin, thyroid hormones, and some other drugs can stimulate appetite. Anesthetics can interfere with taste. Calcium in milk can diminish the absorption of some antibiotics. Be sure to discuss any possible interactions with the licensed practitioner or dietitian before discussing diet and drug regimens with a patient.

► Eating Disorders

LO 55.7

Eating disorders, characterized by extremely harmful eating behavior, can lead to health problems. These disorders can damage the body and even cause death. They are most common in adolescent girls and young women, although 10% to

15% of patients with eating disorders are male. Refer to the *Points on Practice* feature to identify the signs and symptoms of common eating disorders.

Anorexia Nervosa

Anorexia nervosa is an eating disorder in which people starve themselves. They fear that if they lose control of eating, they will become grossly overweight. They lose an excessive amount of weight and become malnourished, and women often stop menstruating. The typical patient with anorexia nervosa is a high-achieving, white female in her teens or early 20s. The numbers of children and middle-aged women who suffer from the disorder, however, have been increasing. The cause of anorexia remains unknown, but risk factors include

- Coming from a family that has problems with alcoholism.
- Suffering a childhood trauma, such as sexual abuse (20% to 50% of patients were sexually abused).
- Having a high stress level.
- Suffering from depression.
- Suffering from shame and low self-esteem.
- Having an extreme need to be in control.

It also has been noted that anorexia tends to run in families. The victim of anorexia often uses food as a way to deal with the psychological effects of trauma by numbing the emotions or as a means of getting some measure of control in life. Anorexia can be precipitated by any major life change.

This disorder can be fatal. The first stage of treatment is to restore normal nutrition. Patients may need to be hospitalized and fed intravenously or by nasogastric tube, which enters through the nose and delivers food into the stomach. Hospitalization may be necessary because patients with excessive weight loss may develop cardiac and other medical disorders. These patients also may be at risk for suicide. The hospital stay may eventually provide patients with the structure and support they need to establish healthy eating patterns.

Psychotherapy is essential and involves a combination of one-on-one and group therapy. Therapy groups that are single-sex rather than coed are preferable because of the different gender and peer group issues men and women face. Licensed practitioners may prescribe medication for depression and anxiety. The later stages of treatment include teaching patients and their families about nutrition concepts.

Bulimia

Bulimia nervosa is an eating disorder in which people eat a large quantity of food in a short time (bingeing) and then attempt to counter the effects of bingeing by self-induced vomiting, use of laxatives or diuretics, and/or excessive exercise. People with bulimia may use such behavior to try to gain control of their lives and weight.

Bulimia can be triggered when a slightly overweight person diets but fails to achieve the goal. Episodes are usually frequent, rapid, and uncontrollable. The behavior may occur only during periods of stress.

People with bulimia often diet when not bingeing. Psychologically, they believe their worth depends on being thin.

POINTS ON PRACTICE

Recognizing the Signs and Symptoms of Common Eating Disorders

As a medical assistant, one of your primary responsibilities is to interview patients about their medical histories. It is important to know the signs and symptoms of eating disorders in order to accurately form questions to gain complete medical information for the licensed practitioner.

Anorexia Nervosa

- Unexplained weight loss of at least 15%
- Self-starvation
- Excessive fear of gaining weight
- Malnourishment
- Cessation of menstruation in women
- Drastic reduction in food consumption
- Denial of feeling hungry
- Ritualistic eating habits
- Overexercising
- Unrealistic self-image as being obese
- Extremely controlled behavior

Bulimia

- Eating large quantities of food in a short period, followed by purging
- Pretexts for going to the bathroom after meals
- Using laxatives or diuretics to control weight
- Buying and consuming large quantities of food
- Feeling out of control while eating
- Maintaining a constant weight while eating a large amount of fattening foods
- Mood swings
- Awareness of having a disorder, but fear of not being able to stop
- Depression, self-deprecation, and guilt following the episodes

Binge Eating

- Bingeing on food, not followed by purging
- Weight gain

Behind their cheerful exterior, they usually feel depressed, lonely, ashamed, and empty.

Most bulimics who seek help are in their early 20s and report that they have been bulimic for 4 to 6 years. Because they are more likely to want and seek help, they are slightly easier to treat than anorexics are.

Bulimia is usually not life-threatening, but it can cause the following serious health problems:

- Erosion of tooth enamel
- Enlarged salivary glands
- Lesions in the esophagus
- Stomach spasms
- Chemical and hormonal imbalances

As with anorexia, treatment for bulimia involves a combination of psychotherapy and medication. Dental work, medication for depression and anxiety, nutritional counseling, and support groups may be used. The goal is to establish a healthy weight and good eating patterns as well as to resolve the psychosocial triggers.

Getting Help

Studies show an unsatisfactory rate of recovery from eating disorders; only about half of anorexic patients fully recover. The disorders can become chronic, with periods of remission and relapse. Chronic anorexia can be fatal, and many people who do recover from eating disorders remain preoccupied with food.

If you suspect that a patient has an eating disorder, be alert for the following eating or activity patterns that the patient might mention in conversation:

- Skipping two or more meals a day or limiting caloric intake to 500 or fewer calories a day
- Eating a very large amount of food in an uncontrollable manner over the course of 2 hours
- Eating large quantities of food without being hungry
- Using laxatives, excessive exercise, vomiting, diuretics, or other purges for weight control
- Avoiding social situations because they may interfere with a diet or exercise
- Feeling disgust, depression, and guilt after a binge
- Feeling that food controls life

► Patient Education

LO 55.8

Whenever you teach patients about nutrition and diet, you help them take steps to improve their health. In most instances, a licensed practitioner or dietitian gives the patient instructions, which you then reinforce. Patients may feel more comfortable asking you questions about their diet than asking other members of the healthcare team. They may think their concerns are too trivial or simple for the practitioner or dietitian.

Because of your frequent contact with patients, you can play a major role in education. You can teach patients about the role of nutrition in helping to prevent specific medical conditions. You also can teach patients how to be wise consumers when they shop by reading food package labels. You will be better equipped to educate patients and answer their questions if you have a solid knowledge of diet and nutrition and if you stay current with recent research findings. See the

Educating the Patient section for information on the relevance of such research. Before discussing a diet with any patient, be sure you understand the regimen the practitioner or dietitian is recommending as well as how to implement it.

If you are unsure of answers to any patient's questions, always ask the licensed practitioner. Refer patients who have questions about meal patterns and food selections to the registered dietitian, if one is available.

Your Role in Patient Education

When discussing dietary requirements with a patient, keep in mind that the patient is always the focus of nutritional care. Specific factors to take into account include the following:

- Any psychological or lifestyle factors that affect food choices and behaviors. Learn about the patient's dietary likes and dislikes, as well as religious or cultural restrictions, before you suggest the use of specific foods in meeting dietary requirements.
- The patient's age and family circumstances. For example, parents need to know the specifics about an infant's or a child's diet. An elderly person's diet needs to be physically and economically manageable as well as nutritious.
- Diseases and disorders. For example, if the patient has chewing or breathing problems or is nauseous, the licensed practitioner will have to prescribe treatments or medications to address those problems.
- The patient's psychological condition. You can learn a great deal about psychological status through discussion and nonverbal cues. For instance, you might look for signs that the patient is frustrated with the dietary changes or is in denial about a problem. The greater the rapport you develop with a patient, the more you will be able to help.

Remind patients that eating healthfully will help them feel and look better and help their bodies work better. When the licensed practitioner prescribes therapeutic diets, be sure patients are fully aware of the reasons they must follow the diets. Help patients set realistic goals and praise them for even the smallest accomplishments. Offer positive reinforcement for current and new good food habits.

As with all patient education, teaching methods such as role-playing, repetition of concepts, and the use of literature and other media reinforce your discussion. Use printed and audiovisual materials. Patient education sessions can be formal or informal and can take place at any appropriate time and place, such as in the office, over the telephone, or during a treatment or procedure. If possible, let patients decide which arrangements they prefer, or let them know the schedule in advance.

Patients need your support and empathy in working toward diet and nutrition goals, whether preventive or therapeutic. Follow these guidelines for best results when discussing diets with patients:

- Treat each patient as an individual with unique eating habits, knowledge of nutrition, and ability to learn.
- Teach a small amount of material at a time; 15- to 30-minute sessions are better than hour-long ones.

- Keep explanations at the level of the patient's understanding and vocabulary.
- Emphasize the patient's good eating behavior to reinforce it.
- Let the patient play an active role in the learning process—for example, by helping to plan the diet.
- Give the patient a written dietary plan to take home as well as any other helpful materials you have to offer.
- Suggest that the patient contact local support groups to connect with people who are trying to maintain the same kind of diet.

Nutritional education is part of preventive healthcare. Documentation is necessary to ensure payment by managed care and other health insurance providers. Failure to document can jeopardize a patient's insurance coverage. Document all patient education, including the specific topic, the amount of involvement by the patient, what types of materials were used, and if follow-up is planned. The progress note for Hilda Grubber is an example of nutritional documentation.

BWW **PROGRESS NOTE**

Patient Name:	Hilda Grubber
	Discussed low-calorie diet, exercise, and weight loss with patient. Patient encouraged to ask questions. 1,800-calorie diet menu provided. Contact information provided for Weight Watchers. Patient scheduled for follow-up appointment in 6 weeks.
Date:	4/30/XX

Cultural Considerations

Eating is a personal and social activity, and cultural issues play an especially important part in diet and nutrition. A person's cultural heritage, religious background, family traditions, socioeconomic status, and personal beliefs help determine eating habits and preferences. Culture and lifestyle also help shape food purchasing and serving habits, likes and dislikes, meal timing and frequency, attitudes toward food supplements, and the tendency to snack.

Dietitians and nutritionists who design diets and recipes for patients know that successful diets must take into account cultural and lifestyle factors. You can increase the effectiveness of your patient education if you become familiar with the food habits and beliefs common to your patients' cultural backgrounds. Learn to recognize the eating patterns belonging to different cultures and make a special effort to familiarize yourself with the food preferences of the ethnic groups most commonly represented among the patients in the practice where you work.

EDUCATING THE PATIENT

Changes in Nutritional Recommendations

In the field of nutrition—as in other scientific fields—research continues to provide people with additional information. You can help answer patients' questions about the potential usefulness of new information by understanding the difference between initial research findings and those evaluated and endorsed by the government. In many cases, information is not officially released or endorsed until the government has studied the facts and determined that they are accurate and concrete enough for public consideration. For example, *initial findings* have suggested the following information:

- Beta-carotene supplements may provide no benefit and may even be harmful.
- Certain fruit-derived flavonoids—pigmented antioxidants—may help halt the growth of cancer cells.
- Vitamin D may reduce the risk of certain cancers.

Patients may read about research studies and ask whether they should make whatever dietary changes the findings suggest. You need to explain that such findings are preliminary and not formally approved by a government agency. Although the approval process is lengthy—requiring a significant amount of data and test results—it provides a system for protecting consumers from false nutritional claims.

Tell patients that once the government determines that a nutritional recommendation is warranted, it often acts on it. One example is the case of folate. Since the 1960s, a number of studies have been conducted on the importance of folate in the diet. Over the years, those studies have yielded the following results:

- Folate offers protection from neural tube defects in unborn babies.
- Folate can reverse certain anemias.
- Folate may reduce the risk of cervical dysplasia.
- Folate appears to lower the likelihood of heart attacks.

As a result of these studies, the Department of Health and Human Services' Food and Drug Administration considered folate to be so important to all people that it approved the addition of folate to flour. Several nutrients have long been added to certain products to improve the products' nutritional value and to increase people's intake of important nutrients lacking in the general diet:

- Vitamin A and vitamin D, added to dairy products
- Iodine, added to salt
- Niacin, added to milled grain products
- Various vitamins and minerals, added to processed cereals

Explain to patients that nutritional recommendations change as scientists learn more about the ways various foods affect the human body and the exact amount of nutrients the body requires. Keep up-to-date on nutrition research so that you can provide patients with the latest information and help them steer clear of unsubstantiated claims.

Organizations such as the American Dietetic Association, American Heart Association, and many others have Internet sites that provide excellent information about diet and nutrition. Websites such as <http://www.health.gov> are available to you and your patients.

PROCEDURE 55-1 Teaching Patients How to Read Food Labels

WORK // DOC

Procedure Goal: To explain how patients can use food labels to plan or follow a diet

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Patient chart/progress note, food labels from products

Method:

1. Identify the patient and introduce yourself.
2. Explain that food labels can be used as a valuable source of information when planning or implementing a prescribed diet.
3. Using a label from a food package, such as the ice-cream label in Figure Procedure 55-1 Step 3, point out the Nutrition Facts section.
4. Describe the various elements on the label.

- Serving size is the basis for the nutrition information provided. One serving of the ice cream is $\frac{1}{2}$ cup. There are 12 servings in the package of ice cream.

RATIONALE: *Paying close attention to the serving size and how many servings are in a container helps determine how many servings are being consumed.*

- Calories and calories from fat show the proportion of fat calories in the product. One serving of the ice cream contains 140 calories and 60 calories of each serving comes from fat.
- The (%) Daily Value section shows how many grams (g) or milligrams (mg) of a variety of nutrients are contained in one serving. Then the label shows the percentage (%) of the recommended daily intake of each given nutrient (assuming a diet of 2,000 calories a day). The ice cream contains 23% of a person's

recommended daily saturated fat intake and no dietary fiber.

- Recommendations for total amounts of various nutrients for both a 2,000-calorie and a 2,500-calorie diet are shown in chart form on the side of the label. These numbers provide the basis for the daily value percentages.
 - Ingredients are listed in order from largest quantity to smallest quantity. In this half-gallon of ice cream, milk, cream, sugar, and skim milk are the most abundant ingredients.
5. Inform the patient that a variety of similar products with significantly different nutritional values are often available. Explain that patients can use nutrition labels to evaluate and compare such similar products. Patients must consider what a product contributes to their diets, not simply what it lacks. To do this, patients must read the entire label. Compared with the regular ice cream, the “light” ice cream contains less fat, fewer carbohydrates, as well as less sodium and cholesterol.
 6. Ask the patient to compare two other similar products and determine which would fit in better as part of a healthful, nutritious diet that meets that patient’s individual needs.
 7. Document the patient education session in the patient’s chart, indicate the patient’s understanding, and initial the entry (Refer to Progress Note).

FIGURE Procedure 55-1 Step 3 Food labels are a source of nutrition information. This label provides facts on the nutrients and ingredients contained in this homestyle vanilla ice cream.

Patient education session for low-fat diet. Patient given a written pamphlet. Patient stated knows the reason for a low-fat diet but may have trouble staying on the diet because she likes to eat ice cream. Shown ice-cream food labels and practiced identifying type of ice cream with least amount of fat. Patient had no questions.

RATIONALE: Many insurance companies require evidence of preventive health counseling, and documentation is an important aspect of patient insurance coverage.

FIGURE Procedure 55-1 Step 5 By reading this label, a patient would learn that this light ice cream contains less sugar, fat, cholesterol, and sodium, and has fewer calories than regular ice cream.

PROCEDURE 55-2 Alerting Patients with Food Allergies to the Dangers of Common Foods

WORK // DOC

Procedure Goal: To explain how patients can eliminate allergy-causing foods from their diets

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues

Materials: Results of the patient’s allergy tests, patient’s chart/progress note, pen, patient education materials

Method:

1. Identify the patient and introduce yourself.

2. Discuss the results of the patient's allergy tests (if available), reinforcing the licensed practitioner's instructions. Provide the patient with a checklist of the foods that the patient has been found to be allergic to and review this list with the patient.
3. Discuss with the patient the possible allergic reactions those foods can cause.
RATIONALE: *The patient should know what signs to look for in the event an allergic reaction to food occurs so that he or she can react quickly and appropriately.*
4. Discuss with the patient the need to avoid or eliminate those foods from the diet. Point out that the patient needs to be alert to avoid the allergy-causing foods not only in their basic forms but also as ingredients in prepared dishes and packaged foods. (Patients allergic to peanuts, for example, should avoid products containing peanut oil as well as peanuts.)
5. Tell the patient to read labels carefully and to inquire at restaurants about the use of those ingredients in dishes listed on the menu.
6. With the licensed practitioner's or dietitian's consent, talk with the patient about the possibility of finding adequate substitutes for the foods if they are among the patient's favorites. Also discuss, if necessary, how the patient can obtain the nutrients in those foods from other sources (for example, the need for extra calcium sources if the patient is allergic to dairy products). Provide these explanations to the patient in writing, if appropriate, along with supplementary materials such as recipe pamphlets, a list of resources for obtaining food substitutes, and so on.
7. Discuss with the patient the procedures to follow if the allergy-causing foods are accidentally ingested.

RATIONALE: *Do not assume a patient will know what to do in the event of an allergic reaction.*

8. Answer the patient's questions and remind the patient that you and the rest of the medical team are available if any questions or problems arise later on.
9. Document the patient education session or interchange in the patient's chart, indicate the patient's understanding, and initial the entry (Refer to Progress Note).

RATIONALE: *Many insurance companies require evidence of preventive health counseling, and documentation is an important aspect of patient insurance coverage.*

BWW PROGRESS NOTE
✕

Patient Name:

Date:

Author:

Patient tested positive for peanut allergy. Explained the dangers of exposure to peanuts as well as products cooked in peanut oils. Instructed to read package and inquire at restaurants before eating foods. Patient restated how to use EpiPen and other emergency actions in case an exposure to peanuts occurs. Education brochure provided to patient.

SUMMARY OF LEARNING OUTCOMES

LEARNING OUTCOMES	KEY POINTS
55.1 Relate daily energy requirements to the role of calories.	The body uses food for three major purposes: to provide energy; to build, repair, and maintain body tissues; and to regulate body processes. Calories provide energy for the body. Calories are measured in the foods we eat. We also can estimate the amount of calories used by the body during activity.
55.2 Identify nutrients and their role in health.	The body needs a variety of nutrients for energy, growth, repair, and basic processes. Several food components provide nutrients. These are proteins, carbohydrates, fiber, lipids, vitamins, minerals, and water.
55.3 Implement a plan for a nutritious, well-balanced diet and healthy lifestyle using the USDA's guidelines.	Dietary guidelines suggest the types and quantities of food that people should eat each day. They also may contain the recommendations about which types of foods to limit and which types of foods to increase. MyPlate provides recommendations for eating a variety of nutrients and maintaining physical activity. Using MyPlate recommendations promotes a well-balanced diet and healthy lifestyle.

LEARNING OUTCOMES	KEY POINTS
55.4 Describe methods used to assess a patient's nutritional status.	Calipers are used to perform a skinfold test that determines the percentage of body fat. BMI is the body mass index. Both measurements, along with other factors, may be used to assess a patient's nutritional status.
55.5 Explain reasons that a diet may be modified.	Dietary modifications may be used alone or in combination with other therapies to prevent or treat illness.
55.6 Identify types of patients who require special diets and the modifications required for each.	Patients with allergies, anemia, cancer, diabetes, heart disease, hypertension, lactose sensitivity, or obesity need special diets. In addition pediatric, pregnant, lactating, and debilitated patients as well as those undergoing drug therapy need modifications to their diet.
55.7 Describe the warning signs, symptoms, and treatment for eating disorders.	You should know the signs and symptoms of eating disorders in order to evaluate for these disorders during the patient interview: • Anorexia nervosa—unexplained weight loss, self-starvation, and fear of weight gain • Bulimia nervosa—eating large quantities of food in a short period of time, going to the bathroom immediately after eating, and using laxatives to excess • Binge eating—eating large quantities of food, not followed by purging, and weight gain
55.8 Educate patients about nutritional requirements.	Patients need to be educated about special diets and how to implement dietary changes as instructed by licensed practitioners and dietitians. Knowledge of basic nutritional principles and current nutritional findings is necessary. Documentation is required to help ensure payment by managed care and other health insurance companies.

CASE STUDY CRITICAL THINKING

© David Sacks/Getty Images

Recall Mohammad Nassar from the beginning of this chapter. Now that you have completed this chapter, answer the following questions:

1. What is the patient's probable diagnosis?

2. Do you think that the patient's attention to calorie intake is simply, as he says, preparation for wrestling competition?
3. Why is this patient experiencing muscle weakness?

EXAM PREPARATION QUESTIONS

- (LO 55.6) What is the most highly recommended food for a patient less than 6 months old?
 - Single-grain baby cereal
 - Iron-fortified infant formula
 - Breast milk
 - Whole milk
 - Two percent milk
- (LO 55.5) Which of the following foods should not be given to a patient with lactose sensitivity?
 - Cheese
 - Broccoli
 - Chicken
 - Eggs
 - Bananas

3. (LO 55.3) Which of the following is a key recommendation of the USDA Dietary Guidelines?
 - a. Reduce physical activity to less than 2 days per week
 - b. Reduce sodium intake to less than 2,300 mg a day
 - c. Consume no more than three alcoholic beverages a day
 - d. Consume at least 500 mg of cholesterol a day
 - e. Avoid oils and use solid fats for cooking
4. (LO 55.2) On average, an adult should drink _____ glasses of water a day.
 - a. 2 to 8
 - b. 6 to 8
 - c. 4 to 10
 - d. 4 to 6
 - e. 2 to 6
5. (LO 55.2) Which of the following statements about protein is correct?
 - a. Protein decreases the rate of carbohydrate breakdown and absorption
 - b. Protein serves as a constituent of bile, which aids in digestion
 - c. Protein assists with antibody production and disease resistance
 - d. Protein provides a concentrated source of heat and energy
 - e. Protein flushes out wastes
6. (LO 55.4) Which of the following *best* describes the skinfold test?
 - a. Measures body fat based on height and weight of adult men and women
 - b. Depends on the amount of water intake over the past 24 hours
 - c. Pinches the skin with a caliper to determine the weight of a patient
 - d. Measures fat as a percentage of body weight
 - e. Requires a formula to be determined
7. (LO 55.1) Which of the following is *not* a part of the process of nutrition?
 - a. Absorption
 - b. Elimination
 - c. Intake
 - d. Metabolism
 - e. Indigestion
8. (LO 55.8) Which of the following guidelines would you *least* likely use when educating a patient about nutrition?
 - a. Treat each patient as an individual with unique eating habits, knowledge of nutrition, and ability to learn
 - b. Teach an eating plan that you have developed using specific dietary guidelines
 - c. Teach a small amount of material at a time; 15- to 30-minute sessions are better than hour-long ones
 - d. Keep explanations at the level of the patient's understanding and vocabulary
 - e. Emphasize the patient's good eating behavior to reinforce it
9. (LO 55.7) A patient is 5'6" and weighs 145 lb, which is the same as her last visit 6 months ago. She says she can easily eat at least a dozen donuts for breakfast and her mother is always telling her she is moody. You know you need to report this information to the licensed practitioner because it is possible the patient has
 - a. Anorexia
 - b. Lactose intolerance
 - c. Bulimia
 - d. Binge eating
 - e. Hypertension
10. (LO 55.5) Which of the following diets may be prescribed for a patient who has difficulty swallowing?
 - a. Soft diet
 - b. Low-cholesterol diet
 - c. Low-sodium diet
 - d. High-fiber diet
 - e. High-carbohydrate diet

SOFT SKILLS SUCCESS

A 14-year-old female has come to the office with a fever of 100.2 and complaining of a sore throat. You check her weight from the previous visit and notice she has lost 20 pounds. Although she appears of normal weight for her size, when you mention she has lost 20 pounds in a disgusted tone she says, "I just wish I could lose a few more. I am so tired of being such a big cow. I really don't think my weight is any of your business!" What should you say to or do for this patient?

Practice Management

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Cindy Chen	07/15/19XX	NKA
PATIENT INFORMATION	Attending	MRN	Other Information
	Alexis N. Whalen, MD	324-86-542	Medication(s): Retrovir®

Cindy Chen is a 28-year-old HIV-positive female who is a patient of Dr. Whalen. Since adding Retrovir® to her management, she is again feeling well and has actually gained a few pounds. Cindy has recently completed a phlebotomy course at the local community college—in fact, she did her externship at BWW Medical Associates and did very well.

© Red Chopsticks/Getty Images RF

There is an opening at BWW for a phlebotomist and Cindy has applied for the position. The staff all like Cindy and would like to be part of her “new lease on life.”

Keep Cindy in mind as you study the chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 56, you will be able to:

- 56.1** Explain the basic organizational designs of the medical office and the relationship of the physician and the medical assistant with the practice manager and direct supervisors.
- 56.2** Describe the responsibilities of the practice manager.
- 56.3** Summarize the basic human resources functions in practice management.
- 56.4** Distinguish four of the possible traits of someone with leadership skills and the importance of these skills to the healthcare team.
- 56.5** Compare risk management and quality assurance in a medical facility.
- 56.6** Calculate an employee's gross earnings, deductions, and net earnings for a pay period.
- 56.7** Describe the tax forms commonly used in the medical office and the purpose of the office tax liability account.

KEY TERMS

- | | |
|--|--------------------------------------|
| agenda | incident report |
| budget | labor relations |
| chain of command | mediation |
| diversity | midlevel provider |
| employee handbook | net earnings |
| Federal Insurance Contributions Act (FICA) | organizational chart |
| Federal Unemployment Tax Act (FUTA) | policies and procedures (P&P) manual |
| Form I-9 | probationary period |
| Form W-2 | quality assurance (QA) |
| Form W-4 | risk management (RM) |
| grievance process | sexual harassment |
| gross earnings | tax liability account |

- I.C.12** Identify quality assurance practices in healthcare
- V.P.4** Coach patients regarding:
 - (a) office policies
- V.A.1** Demonstrate:
 - (a) empathy
 - (b) active listening
- X.C.3** Describe components of the Health Information Portability and Accountability Act (HIPAA)
- X.C.5** Discuss licensure and certification as they apply to healthcare providers
- X.C.7** Define:
 - (i) risk management
- X.C.9** List and discuss legal and illegal applicant interview questions
- X.P.7** Complete an incident report related to an error in patient care
- XI.C.3** Identify the effects of personal morals on professional performance

4. Medical Law and Ethics

- f. Comply with federal, state, and local health laws and regulations as they relate to healthcare settings

8. Medical Office Business Procedures/Management

- f. Display professionalism through written and verbal communications

11. Career Development

- b. Demonstrate professional behavior

► Introduction

In previous chapters, you have explored many of the complex systems, procedures, requirements, and roles required in the modern medical office. Today, it is much more difficult for the practitioner to care for patients and manage the office as he or she may have done in the past. While the healthcare facility's management differs by ownership, size, and other variables (addressed in the *Legal and Ethical Issues* chapter), one person is generally in charge of overseeing the day-to-day operations, working closely with the licensed practitioners to keep the practice running smoothly and its staff working at its professional peak (Figure 56-1). The title of this person has varying names, including *practice* or *office manager*, *executive*, or *director* and *healthcare administrator*. This chapter discusses this person's position, responsibilities, and relationship with the practitioners and medical assistant. The terms *medical practice manager* and *office manager* represent the role. Employee management functions, including human resources and facility management, also are discussed in this chapter.

► Organizational Design

LO 56.1

Every medical office has an organizational design, which may or may not be represented by a formal **organizational chart**. The design and chart show the supervisory structure and reporting relationships between different functions and positions—in other words, who is responsible for whom and for what. In most states, the medical assistant is required to be under the direct supervision of the physician, physician assistant, or nurse practitioner for direct patient care activities. However, the practice manager or that person's designee

is usually responsible for interviewing, hiring, firing, evaluating, and ensuring training and credentialing, which are all considered administrative and not direct patient care

FIGURE 56-1 As the practice manager of BWW Medical Associates, Malik Katahri keeps the practice running smoothly.

© HBSS/Corbis RF

FIGURE 56-2 Practice organizational chart for a physician-owned practice.

functions. Both physician-owned and company-owned medical practices rely on some form of organizational design to function effectively.

Physician-Owned Medical Practice

Figure 56-2 represents a physician-owned practice's simplified organizational chart. As you learned in the *Legal and Ethical Issues* chapter, a physician-owned medical practice sometimes obtains the legal designation of a professional corporation (PC). The owner is usually an individual doctor or a group of physicians. In the organizational chart in Figure 56-2, the placement of the boxes and arrows shows that the physician carries the ultimate responsibility but designates it to the person below him—the practice manager. The practice manager reports to the physician, who also pays her salary. The manager is the physician's employee who oversees the daily operations and the administrative functions of the entire office and staff, including the medical assistants. The arrow from the physician to the medical assistants demonstrates that the physician also has direct responsibility for the medical assistants. As mentioned previously, this responsibility involves direct patient care. Depending on the size of the practice, other supervisory personnel might report to the practice manager. Each supervisor would then have staff reporting directly to him or her. In multispecialty organizations, supervisors might be designated by specialty, such as pediatrics, internal medicine, and cardiology.

Company-Owned Medical Practice

Figure 56-3 represents a simplified organizational chart of a company-owned medical facility. The company may be non-profit, such as a community health center, or for-profit, such as Cigna HealthCare. The president or chief executive officer (CEO) has the ultimate responsibility. However, again, the practice manager is in charge of the day-to-day operations, with the exception of direct patient care functions. The medical director is in charge of the patient care end of the practice, overseeing the physicians, nurses, **midlevel providers** (physician assistants and nurse practitioners), and medical assistants. The dotted line between the practice manager and the medical director indicates that they are equal in rank and collaborate with each other. The dotted line from the practice manager to the other physicians indicates collaboration. For example, the practice manager may work with the physicians to help obtain documentation of credentials, but the medical director has the majority of the responsibility for the providers, including their schedules and periodic evaluations. The president, the practice manager, the medical director, and other physicians and staff are paid employees of the company. A board of directors is ultimately responsible for the practice, through the CEO, but this board is not involved in the company's daily operations.

The Chain of Command

The term **chain of command** began in the military to demonstrate how each rank is accountable to those directly superior and how authority passes from one link in the chain to the next from bottom to top or top to bottom. For example, in the military, a private is accountable to a sergeant, who is accountable to a lieutenant, and so on. The lieutenant gives an order to the sergeant, who gives it to the private. Each level of the chain has many steps, including the determination of the equipment, training, and strategies needed to carry out the order or mission. The majority of today's businesses, including medical practices, operate using this approach.

It is important to understand the chain of command in your facility and to understand who your supervisor is. Since medical assistants work closely with physicians, the tendency may be to go to the physician with requests such as asking for time off. If the physician is not your supervisor, it is inappropriate

FIGURE 56-3 Practice organizational chart for a company-owned medical practice.

to “go over your supervisor’s head” and make the request of the physician, as he may not have the authority to grant your request. It is also inappropriate to go outside the chain of command with a complaint, even if the complaint is about your supervisor. First, address the issue with your supervisor. If this issue is not resolved, then go to the next person in the chain of command, such as the practice manager. Most offices have policies and procedures for handling complaints. Should you seek other employment, that organization will contact your previous supervisor for references. No matter how friendly or informal the medical practice is, stay within the chain of command.

► Managing the Medical Practice LO 56.2

The practice manager’s role includes providing communication avenues for all medical team members as well as communicating with members of the community outside the medical practice. The practice manager is also responsible for ensuring that legal, business, health, and safety requirements are in compliance; guaranteeing the adequacy of the technology and physical plant; providing for the practice’s financial viability; and monitoring risk management and customer care and satisfaction. Sometimes, the manager is also in charge of multiple satellite offices.

By now, you have probably realized that in today’s complex healthcare world, any medical assistant who aspires to become a practice manager will need additional education and training to attain this goal. The information in this chapter will introduce you to the role so that you can begin to understand all aspects of running a medical office and think about all the possibilities that may be open for you once you become a certified medical assistant. Your path will be up to you.

Communication Skills of the Practice Manager

The *Interpersonal Communication* chapter describes general communication techniques used in communication with patients, persons with special needs, and coworkers. The *Written and Electronic Communication* chapter outlines the general practices for producing effective and professional written communication. The practice management position requires exceptional verbal and written communication skills and excellent interpersonal skills. The following are some of the routine individuals and groups with whom the practice manager communicates on a regular basis:

- Staff
- Patients
- Physicians/practitioners (within the practice and in other practices)
- Hospitals
- Insurers
- Vendors
- Employers
- Contractors
- Governmental agencies
- Other regulatory and professional agencies

- Educational facilities
- Bankers
- Attorneys
- Community organizations

Communicating with each individual and group requires knowledge of the business or situation and, often, excellent problem-solving techniques. The manager’s role is also to ensure that all communication is appropriate, respectful, timely, and HIPAA compliant. Many offices have policies and procedures related to communication, especially electronic communication.

The Policies and Procedures Manual

The **policies and procedures (P&P) manual** is a key written communication tool in the medical office. Both permanent and temporary employees use this manual, which covers all office policies for administrative and clinical procedures. The practitioner (or practitioners), practice manager, and staff (often including the medical assistant) usually develop this manual as a joint effort. See Figure 56-4.

Policies are rules or guidelines that dictate an office’s day-to-day workings. Although individual policies vary from office to office, most medical office manuals describe the following policy areas:

- Office purposes, objectives, and goals as set by the practitioner(s)
- Rules and regulations
- Job descriptions and duties of staff personnel
- Office hours
- Dress code
- Insurance and other benefits
- Vacation, sick leave, family medical leave, and other time away from the office
- Salary and performance evaluations
- Maintenance of equipment and supplies
- Mailings
- Bookkeeping
- Scheduling of appointments and maintenance of patient records
- OSHA guidelines

Policies This section of the manual typically includes the chain of command for the office and/or the person to whom each employee reports. The policy section often also includes the statement of intent or goal intended, resulting in the procedures that follow.

Procedures The procedure—the map for reaching the goal stated in the policies section—spells out the correct manner for carrying out each policy. For example, a policy might state that OSHA guidelines for bloodborne pathogens will be maintained by all staff at all times. The accompanying procedure then describes the steps expected to maintain bloodborne pathogen guidelines. Facilities may have more than one P&P manual, such as one for human resources, one for safety, one for clinical

POLICY AND PROCEDURE

Subject: Competency of Staff

Date of Issue: Sept. 25, 20XX

Policy # 1001

Effective Date: Oct. 1, 20XX

I. POLICY

It is the policy of BWW Medical Associates, PC that all employees meet the standards of competency as defined by its various policies and the requirements of TJC and other regulatory and credentialing agencies.

II. PURPOSE

The competence of staff members is (a) defined by job descriptions designed by the director; (b) assessed initially during the orientation process; (c) maintained through educational updates; and (d) evaluated periodically in conjunction with the performance appraisal process.

III. IMPLEMENTATION

a. Job Descriptions

i. The office manager will write and/or review each job description annually. Each job description will reflect the educational experience and training needed for the position and include competency-based performance standards.

FIGURE 56-4 Sample policy statement from the BWW Medical Associates policies and procedures manual.

procedures, and one for administrative procedures. The practice manager must stay current with new practices and standards of the community and all applicable professional organizations, updating the office manual as required. In addition, new laws and requirements of governmental agencies such as OSHA and CMS must be monitored and incorporated. Reading the policies and procedure manual(s) is typically part of new employee orientation. Each employee should know the location of the policies and procedures manual; an employee should look here if he or she is unsure about a specific duty or task.

The *clinical procedures* portion of a P&P manual should include instructions regarding the following for each test performed:

- Purpose of the test, clinical application, and usefulness
- Specimen required and collection method; special patient preparation or restrictions
- Reagents, standards, controls, and media used; special supplies
- Instrumentation, including calibration and schedules
- Step-by-step directions

The *administrative procedures* portion of a P&P manual may include instructions regarding the following procedures:

- Appropriate telephone procedures for emergency and non-emergency calls
- Releasing of patient PHI
- Guidelines for submission of “clean” claims for each provider
- Templates for frequently created communications such as normal lab and X-ray results

Licenses, Certifications, and Contracts

The medical practice includes many positions and facets that require federal, state, or local approval. Approvals take the form of a license, certification, or other credential or contract. Some are simple procedures; others are more complicated and expensive. Common responsibilities include ensuring that:

- Physicians and midlevel providers are properly licensed and credentialed with CMS and other payers as required and that the credentialing is up-to-date.
- Physician and midlevel provider DEA forms are up-to-date.
- Medical assistants, phlebotomists, coders, and other personnel are properly trained and certified or credentialed according to federal, state, and professional standards.
- Required licenses to operate the facility, such as local business licenses, are up-to-date.

- Insurance requirements, such as malpractice and liability contracts, are up-to-date and reflect current values.
- Health insurance companies, laboratories, attorneys, and service contracts necessary to conduct business are current.
- The practice is compliant with required reporting to authorities, such as that for reporting communicable diseases.

Depending on the healthcare organization's size, the manager may have other employees involved in carrying out these duties. However, the manager has the ultimate responsibility to guarantee that these tasks are completed in a proper and timely fashion.

Budget and Overall Finances

With the exception of large organizations that have a chief financial officer (CFO), the responsibility for the practice finances is part of the manager's extensive role. A **budget** is created annually and reviewed at least monthly. The budget predicts the expenses and revenues related to operations over a given period of time. First, the manager must know the total expenses. Salaries are usually the biggest budget expense. The manager reviews the healthcare insurance and governmental agencies' patient care contracts and other sources of income. Sometimes the manager must renegotiate the contract if costs have risen. If revenues are lower than expected and costs are higher, the manager must make unpopular budget cuts so that the practice remains profitable and able to continue to provide care for the community it serves.

As the office medical assistant, be mindful that financial responsibility is the role of every employee. Even something as seemingly inconsequential as taking pens home from the office can have an impact on the practice. The immediate thought may be "it's just a pen," but the reality is that you did not purchase the pen—the practice did—and if every member of the staff took "only a pen or two," soon there would not be enough pens in the practice. Part of the ethics and integrity of being in the medical profession is your professional behavior—particularly "when no one is looking."

Managing Petty Cash Another budget function that is often managed by the medical assistant with oversight by the practice manager is the petty cash fund. This fund is used to make small (petty) cash disbursements for minor expenses such as postage-due fees or holiday decorations (Figure 56-5). To avoid writing checks for such small amounts, you may pay for them from the petty cash fund (also known as the revolving fund)—cash kept on hand in the office for small purchases. The practice manager often determines the amount of the petty cash account (usually \$50) and the minimum amount of cash to be kept on hand (such as \$15).

Starting and Maintaining a Petty Cash Fund To start the fund with \$50, write a check to "Petty Cash" or "Cash" for that amount. Enter the check in the miscellaneous column of the monthly disbursements journal (refer to the *Patient Collections and Financial Management* chapter). Then, cash the check. Because this money will be used for small disbursements, be sure to get some of it in pennies, nickels, dimes, quarters, and dollar bills. Put this money in a petty cash box.

FIGURE 56-5 Managing petty cash is often the task of the medical assistant.

© McGraw-Hill Education

For each payment from the petty cash fund, obtain a receipt or create a petty cash voucher. The voucher should record the transaction number, date, amount paid, purpose of the expense, your signature (as the person issuing the money), and the signature of the person receiving it. Keep the receipt for any item purchased, along with the completed voucher, in the petty cash box to verify expenses later.

Also, document each petty cash withdrawal on a petty cash record form. Include the transaction number, the date, the payee, a brief description, the amount, and the type of expense (such as office expense, auto expense, or miscellaneous expense). If a space is provided, calculate and record the new balance in the petty cash fund.

Replenishing the Petty Cash Fund At the end of the month (or whenever the fund is low), compare the latest petty cash balance, found in the petty cash record or in the petty cash column of the disbursements journal, to the money in the petty cash box. If you have not kept a running balance, total the receipts and vouchers; then count the cash on hand. Subtract the total amount on the receipts and vouchers (for example, \$35) from the original balance (for example, \$50). The difference (\$15) should equal the cash on hand in the petty cash box (\$15).

To replenish the account, write a check to "Cash" or "Petty Cash" for the amount spent (\$35). Cash the check and add the money to the box, bringing the total back up to the original amount of \$50. Record the check for \$35 in the disbursements journal. Also, total the receipts and vouchers by expense category. Record those totals in the appropriate columns on the disbursement record.

Scheduling and Travel

Ensuring that an adequate number of staff members are on duty at all times for the business to function properly is an additional aspect of the practice manager's role. Scheduling is a job that may be delegated to a supervisor or other

person, depending on the practice's size, but the practice manager monitors it. When office staff members are absent due to vacation, extended illness, or educational purposes, it may be necessary to rearrange remaining staff member schedules to provide coverage. If practitioners are not available to see patients, the office may be closed during their absence.

Sometimes, practitioners and other staff, including medical assistants, travel for educational purposes with expenses covered by the practice, in which case work-related expenses may be reimbursed if the appropriate receipts are kept and an expense report is completed (Figure 56-6). Procedure 56-1, at the end of this chapter, provides practice in completing a travel expense report.

Other Business Functions

The contemporary medical office relies on technology for communication, appointment scheduling, coding, billing, diagnostic test ordering and reporting, prescription refills, and the electronic health record. The office manager evaluates and purchases the systems that fit the practice's needs and budget, facilitates the installation and staff training, then oversees the ongoing operations through an in-house technical support person or through a service contract. Other managerial functions include ensuring the availability of mailing and shipping services, inventory and supply purchases, and appropriate marketing and public relation strategies, which may include websites, brochures, and community event sponsorship.

► Human Resources and Practice Management

LO 56.3

The practice manager's role includes the human resources (HR) component of the medical office. This area of the organization is probably the only one that does not involve the patient directly. If the practice or facility is large, it may have its own human resources coordinator or supervisor who reports to the practice manager. If the practice is smaller, the practice manager often functions as the human resources "department." In the business world, human resources personnel deal with employee-related issues such as hiring, training, benefits, labor relations, and employment termination. Other names for HR include personnel services, personnel department, and people services. Within this section of the chapter, we will follow Miguel A. Perez's experience with the hiring process at BWW Medical Associates.

The Hiring Process

As discussed in the *Legal and Ethical Issues* chapter, federal, state, and local governments regulate many hiring practices, including the Equal Employment Opportunity Commission (EEOC), Fair Labor Standards Act, Equal Pay Act, Age Discrimination in Employment Act, and Americans with Disabilities Act (ADA), as well as the Family Medical Leave Act (FMLA). The FMLA allows employees up to 12 job-protected weeks of unpaid leave for approved medical needs for the employee and certain family members. The EEOC act prevents discrimination. See Figure 56-7. Violations can result in monetary and other penalties. Understanding and staying current with these often complex laws is a major HR role. Table 56-1 outlines some legal versus illegal questions that may be asked during the interview process. Keep in mind, one of the best techniques may be to ask a legal question and then remain quiet. Most people get nervous during silent moments and often end up giving you more information than you asked for.

FIGURE 56-7 The EEOC prevents discrimination based on race, color, religion, sex, or national origin.

© Terry Vine/Blend Images RF

In addition to understanding the laws surrounding the hiring process, it is always best to stress competencies such as teamwork, policies and procedures, and cross-training during the interview process and during orientation. Potential employees should understand the qualities that are important to the practice at which they are seeking employment—they need to know if they will be a good fit in the practice and if the practice will be a good fit for them.

Employee orientation is essential in the personnel management phase. During this process, the new hire gets to see and meet important people within the organization. He or she also gets to know what is expected of the position, as well as gain information about company benefits.

The basics of hiring a successful employee are

- Always try to find the most qualified person for the job.
- Scrutinize and check references carefully.
- Have a salary range so that you can negotiate successfully and pay for the most qualified person.
- Discuss policies and procedures (and expectations) early.
- Train properly and retrain when new technology arrives.

When BWW Medical Associates decided to hire an administrative medical assistant, a job description was written that consisted of the following:

- Name of the organization
- Name of the position
- Employment grade
- Summary of the position
- Job responsibilities
- Requirements and qualifications
- Title of the supervisor

One of the job description requirements was that the applicant have a current CMA (AAMA) or RMA (AMT) certification. The next step was to recruit qualified candidates. Miguel A. Perez was a CMA (AAMA) who applied for the position, and his application was one of those selected. He interviewed very well and, after his references were checked, Miguel was offered the position with an appropriate salary. HR maintains a personnel file for every employee. Malik Katahri, the office manager at BWW, initiated an HR file for Miguel.

Orientation and Staff Development

The human resources department provides orientation for new employees and facilitates training and staff development for established employees. Orientation has three overarching sections: the organization, health and safety, and the employee's job. The US Department of Labor (DOL) publishes and provides online copies of the *Employment Law Guide* that addresses many aspects of each of these sections. An **employee handbook** provides a synopsis of the HR policies and procedures. Employee handbooks and HR policies should address **sexual harassment**, which is a violation of federal and some state laws. The legal definition is *unwelcome verbal, visual, or physical conduct of a sexual nature*

TABLE 56-1 Legal Versus Illegal Interview Questions

Topic	Illegal Questions	Legal Questions
Reliability/attendance	Number of children? Who is going to baby-sit? What religion are you? Do you have preschool-age children at home? What is your marital status? Do you have a car?	What hours and days can you work? Are there specific times that you cannot work? Do you have responsibilities other than work that will interfere with specific job requirements such as traveling?
Citizenship/national origin	What is your national origin? Where are your parents from?	Are you legally eligible for employment in the United States?
References	What is your maiden name? What is your father's surname? What are the names of your relatives?	Have you ever worked under a different name?
Arrests/convictions	Have you ever been arrested?	Have you ever been convicted of a crime? If so, when, where, and what was the disposition of the case?
Disability	Do you have any disabilities?	Can you perform the duties of the job you are applying for?
Birth date	What is your date of birth?	If hired, can you furnish proof that you are over age 18?
Emergency contact	What is the name and address of the relative to be notified in case of an emergency?	What is the name and address of the person to be notified in case of an emergency? (Request only after the individual has been employed.)
Credit history	Do you own your own home? Have your wages ever been garnished? Have you ever declared bankruptcy?	Credit references may be used in compliance with the Fair Credit Reporting Act of 1970 and the Consumer Credit Reporting Reform Act of 1996.
Military service	What type of discharge did you receive?	What type of education, training, or work experience did you receive while in the military?
Languages	What is your native language? Inquiry into how applicant acquired the ability to read, write, or speak a foreign language	Inquiry into languages applicant speaks and writes fluently (if the job requires additional languages)
Organizations	List all clubs, societies, and lodges to which you belong. Are you a union member?	Inquiry into applicant's membership in organizations that the applicant considers relevant to his or her ability to perform the job
Race/color	Inquiry about complexion or color of skin Inquiry about coloring	None
W/C	Have you ever filed for workers' compensation? Have you had any prior work injuries?	None
Religion/creed	Inquiry into applicant's religious denomination, religious affiliations, church, parish, pastor, or religious holidays observed	None
Gender	Do you wish to be addressed as Mr., Mrs., Miss, or Ms.?	None
Address	What was your previous address? How long did you reside there? How long have you lived at your current address? Do you own your own home?	None
Education	When did you graduate from high school or college?	Do you have a high school diploma or equivalent? Do you have a university or college degree?
Personal	What color are your eyes, hair? What is your weight?	Only permissible if there is a bona fide occupational qualification

that is severe or pervasive and affects working conditions or creates a hostile work environment. Other topics in a typical employee handbook are found in Table 56-2.

When Miguel began his employment, he, like all new employees, was on a 90-day **probationary period** or *trial period*. During this time frame, the HR department begins to

facilitate staff development and training. Miguel, along with other staff members, attended training for the new electronic health record system the practice is implementing. Other training may include new policies and procedures, cultural diversity and sensitivity, CPR certification, new equipment, and wellness topics such as stress management.

TABLE 56-2 Typical Topics Found in an Employee Handbook

Welcome Message	EEOC Statement	Personal Communications
Organization mission statement	Employment application	Personnel records
Orientation	Equipment and facility use	Probationary periods
Attendance policies	Electronic communication and device use	Performance reviews and improvement plans
Benefits	Job descriptions	Safety and security
Disability benefits	Grievance process	Risk management and incident reports
Leaves of absence	On-the-job injuries	Sexual harassment guidelines
Bereavement policies	OSHA	(Non) Smoking policy
Holidays	Overtime policies	Substance abuse
Jury duty	Payroll periods	Subpoenas
Confidentiality and HIPAA	ADA statements	Wage increases and adjustments
Continuing education and tuition reimbursement	Disaster preparedness and emergency response	Schedules, accountability, and time-off requests
Dress code	Drug testing	

The trial period allows both the new employee and the organization an opportunity to decide if they are a “good fit.” During the probationary period, the employer may terminate the new employee without cause. Likewise, the employee can also decide to leave the new position with little or no notice.

BWW Medical Associates conducts employee performance reviews at the end of the probationary period and then annually. The performance review typically includes the responsibilities in the job description and a form that includes the professional behaviors discussed throughout this textbook. Salary increases are usually based on the review rating.

Many medical practices also provide tuition reimbursement and reimburse expenses for employees who attend conferences that provide continuing education units so that the employee can maintain the appropriate credentials for his or her position. Copies of all training and staff development activities and certificates are maintained in the employee’s personnel file.

Staff Communication

An effective manager ensures convenient, two-way, open, and consistent avenues of communication with the staff, using the following:

- **Staff meetings.** Staff meetings should be at a consistent time each month when patients are not seen. The time is blocked off in the appointment matrix. The location should allow privacy. An **agenda**, which is a list of meeting topics and the order in which they will be addressed, should be used (Figure 56-8). See Procedure 56-2 at the end of this chapter. Formal minutes (the meeting record) may or may not be kept, but at least meeting notes should be maintained by the practice manager that contain the date and time, who was present and absent, what was discussed, and who was responsible for any follow-up actions. These minutes may be needed for credentialing and licensing agencies or as proof of educational and informational topics addressed and as a tool for staff evaluations.

- **E-mail.** Most offices have e-mail for each employee or group of employees. E-mail is rapid and convenient but should be read and edited carefully. Staff and management messages should maintain a professional tone and responses provided in a reasonable time.
- **Newsletters.** Larger practices may have a monthly or quarterly electronic or hard-copy newsletter, which may be the responsibility of the practice manager. The content usually provides information on what is going on in the practice, new policies and procedures or requirements, accomplishments and awards, and internal and community events, often highlighting staff members or departments.
- **Bulletin boards.** Usually located in the staff lounge, these boards should not contain any confidential or sensitive information, since janitorial staff and others outside the practice may have access.
- **Open-door policy.** This policy, maintained by many practice managers, gives staff the freedom to come talk any time the manager’s office door is open. Staff should be respectful of the manager’s time and, if the topic is involved and lengthy, schedule an appointment.
- **Suggestion boxes.** In some facilities, staff and sometimes patients are encouraged to place ideas in a suggestion box; they can submit the suggestion with a name or anonymously. If the suggestion is implemented, some organizations provide a monetary or other award.

Labor Relations

Labor relations is an HR role referring to issues that arise between employees and management. When most people hear the term *labor relations*, they tend to think of the process of hiring and terminating employees, but other functions relate to labor relations. For instance, overseeing the **grievance process** if an employee feels he or she was unjustly treated comes under the heading of labor relations. HR also may mediate or arrange **mediation** for differences between employees, groups of employees, or employees and management. The mediator’s role

is to facilitate communication between the parties, assist them in focusing on the real issues of the disagreement in a nonadversarial manner, and attempt to reach conflict resolution.

► Being a Leader

LO 56.4

Think about someone you admire and the reasons you admire that person. Now think of three words that describe that person. It will not be surprising if words such as *confident*, *honest*, *responsible*, and *organized* come to mind. These are terms, along with others, that describe leaders. Leaders are people who can influence other people to work toward a common goal, to build a team to accomplish those goals. Do not confuse leadership with supervising. There are many excellent leaders who are not supervisors and probably just as many supervisors who are not effective leaders. Let's look at

why leadership, particularly in the healthcare field, is important and how you can become a leader as a medical assistant.

Becoming a Leader

It may sound strange, but to be a good leader, you must first be a good follower; to learn to lead, you must first understand how to be supervised and have a willingness to follow directions. How can you ask someone to follow your directions if you consistently show an unwillingness to follow your own superior's direction? Other traits of effective leaders are

- A desire to achieve both personal and organizational goals.
- Confidence based on a good understanding of the situation at hand.
- An ability to be a team member and influence other members of the team to accomplish stated goals.
- Excellent communication skills (oral and written).
- An ability and willingness to accommodate change.
- Integrity.
- Willingness, even eagerness, to accept responsibility.
- Realization that goals are best achieved through the efforts of many.
- Giving genuine recognition to others that assist in achieving goals.

Building Your Team Good leaders know that effective teams accomplish goals by capitalizing on each member's strengths. But how do you build a team in a medical office when each healthcare worker's job requires her to focus on her area of expertise so that the office runs smoothly? The key is participation. It is up to the leader to create an atmosphere that values and *encourages* teamwork. To do this, an effective leader

- Ensures that each team member knows her job and performs those tasks to the best of her ability.
- Values each team member and encourages each member's contributions.
- Uses excellent communication skills to build trust between the team members.
- Helps each team member set worthwhile and attainable goals.

Setting Goals Most people say they achieve more when they know what is expected of them. Setting goals allows team members to know and understand those expectations and provides a method to measure their progress and identify areas that require attention. When setting goals, it is important to remember some key points:

- Make goals challenging, but not so much so that the goal is impossible to attain.
- Allow team members to contribute their ideas regarding personal and team goals.
- Make sure that the goal is measurable in some way so that success can be *seen*.
- Make sure to have an action plan to reach the goal. The plan should outline what is to be done, the responsible person, and a time frame for completion of the task.

- The team leader should meet with individuals and teams to evaluate progress. If the goal was met, did it meet expectations? What is working and what needs improving? These evaluations provide the basis for the next goal-setting session.

Diversity and Leadership

We have all heard the sayings “Opposites attract” and “It takes all kinds.” Both are true, and respecting differences will make you a better leader. Keep in mind that if you feel that someone is “different,” it is very likely that person is thinking the same thing about you! **Diversity** includes differences among people in terms of identity, age, sex, race, physical ability, ethnicity, religious beliefs, values and mores, sexual orientation, and personality. Open communication among people who are different from each other leads to an understanding of and respect for those differences. It does not mean you must agree with all the differences or beliefs, but you will develop a respect and acceptance of the right of people to be “different.” The following are some suggestions to help you increase your respect for diversity:

- Communicate openly to increase your awareness of diversity. This will increase your knowledge of similarities and differences among individuals.
- Examine your own feelings. No one is immune to biases, and people tend to stereotype others, which leads to discrimination—the opposite of accepting diversity. What are your biases? Are they hurting your ability to communicate effectively with others? Be honest with yourself.
- Look at each person as an individual and not as part of a group. By communicating with individuals, biases and “walls” begin to come down.
- Learn to value each person’s uniqueness. Every person on the team is valuable and has a contribution to make. Be open to each person’s insight and contribution.
- Keep in mind that in healthcare you must be open and respectful of diversity in order to provide quality care to each patient. This respect must carry over to all members of the healthcare team.

Think back to the beginning of this section and the person you said you admire. Does he or she possess traits you would like to emulate? Many effective leaders learn from their mentors. They also learn not only from their own successes but also from their failures. Anyone can make a mistake—the trick is to not make the same mistake repeatedly. If you do not like the result of something, change how or what you are doing, and the result will change. There is almost always more than one way to accomplish a task; listen to everyone in the office and try new ideas. When you do, you are on your way to not only being a team member, but also a team leader.

The practice manager’s role as a leader in the medical office is not easy but carries the opportunity for many personal and professional rewards. Seeing the healthcare organization provide excellent patient care in a safe, financially sound environment where staff members are happy to come to work is an accomplishment of much pride and satisfaction. To create or sustain this environment, the manager, as in all

positions in healthcare, must stay current in the field by reading appropriate journals and books; attending seminars and courses; maintaining membership in his or her professional organizations; and networking with local, state, and national managers. When you experience your applied training, sometimes called an externship or practicum, think about the practice manager’s many jobs.

Risk Management and Quality Assurance

LO 56.5

The term **risk management (RM)** is defined as plans and processes that continually identify, assess, correct, and monitor functions of the medical office to prevent negative outcomes and minimize exposure to risk and consequent liability. Immediately recognizing and addressing potential problems should be everyone’s focus. Risk management also identifies opportunities for improvement. A simple example of risk management is the procedure you learned for opening and closing the office, discussed in the *Safety and Patient Reception* chapter.

On the other hand, **quality assurance (QA)** procedures ensure that the services provided in the medical practice meet or exceed requirements and standards. Quality assurance encompasses *utilization review (UR)*, which is ensuring that treatment plans and services are appropriate and cost-effective. Determining medical necessity is usually required.

Risk management and quality assurance include almost every aspect of the practice manager’s role and are a huge responsibility. The Joint Commission (TJC) and the National Committee on Quality Assurance (NCQA) review the office’s RM and QA plans and outcomes during accreditation visits. They look for a problem-solving model that follows each issue to resolution, referred to as *closing the loop*. The following is an example of a typical five-step problem-solving model (Figure 56-9):

1. Identification
2. Assessment

FIGURE 56-9 The problem-solving process.

3. Correction (design and implementation of an improvement plan)
4. Monitoring to ensure effectiveness of the plan
5. Reevaluation

In a simple example of problem solving, Malik, the practice manager at BWW Medical Associates, PC, notices that the carpet in the reception area is torn, and the patients and staff are placed at risk of falling (identification). He examines the tear and the entire carpet (assessment). He places tape over the tear and orders replacement carpeting (correction). The staff members are made aware of the tear and asked to

be observant for other tears and similar problems (monitoring of effectiveness). Malik will reevaluate the condition of the carpet at intervals to ensure that it is not a risk for tripping and falling, until the new carpeting is installed.

Incident Reports

An **incident report** (Figure 56-10), or occurrence report, is a form required by a facility when an adverse outcome or event with risk of liability occurs. Refer to Procedure 56-3 at the end of this chapter. A fall caused by torn carpeting, for example, requires an incident report.

Date/time of incident: _____ Location: _____

Name of injured or at-risk party: _____

Circle one: Patient Staff Member Other (complete blank) _____

Address of above party: _____

Phone numbers of above party: home _____ cell _____

Describe the incident (use back of sheet if additional space needed): _____

Describe action(s) taken and by whom: _____

Name(s)/contact information of witnesses: _____

Name(s)/time of all parties notified: _____

Name of person completing report: _____ Date/time: _____

Report submitted to: _____ Date/time: _____

(Submit form to immediate supervisor of area where the incident occurred)

FIGURE 56-10 Typical incident report form.

This report contains only factual information about the incident, no opinions or assumptions. Incident reports are not placed in a patient's medical record, and some institutions prefer that the incident report not be completed in the presence of the injured party. The standard practice is that no copies of an incident report are made, and only the original is maintained in a dedicated risk management file. As part of risk management, the practice manager routinely monitors incident reports and identifies any trends to work on reducing risk. While risk management includes anyone who enters the medical office, quality assurance generally involves the patient and his or her care.

► Handling Payroll

LO 56.6

As a medical assistant, you may be responsible for handling the office payroll (Table 56-3). If so, your duties may include

- Obtaining tax identification numbers.
- Creating employee payroll information sheets.
- Calculating employees' earnings.
- Subtracting taxes and other deductions.
- Writing paychecks.
- Creating employee earnings records.
- Preparing a payroll register.
- Submitting payroll taxes.

Applying for Tax Identification Numbers

Every employer—whether a single practitioner or a corporate practice—must have an employer identification number (EIN). An EIN is required by law for federal tax accounting purposes. To obtain an EIN, complete Form SS-4 (Application for Employer Identification Number) from <http://www.federaltaxid.us> and submit it to the Internal Revenue Service (IRS) at <http://www.irs.gov>. Some states also require employer tax reports, for which the practice must have a state identification number, obtained from the proper state agency.

Creating Employee Payroll Information Sheets

The practice must maintain up-to-date, accurate payroll information about each employee. You should prepare a payroll information sheet with the following information for each employee:

- The employee's name, address, Social Security number, and marital status
- An indication that the employee has completed an Employment Eligibility Verification (**Form I-9**), verifying that the employee is a US citizen, a legally admitted alien, or an alien authorized to work in the United States.
- The employer also must complete a new hire reporting form (NHR) on the employee's behalf and submit it to the applicable state agency before the employee receives her first paycheck. Usually, this form is collected along with the W-4 and I-9 forms. Each state has its own format, but the information gathered is universal. Some states allow electronic submission, while others accept the information via mail. Figure 56-11 shows an example of an NHR form.
- The employee's pay schedule, number of dependents, payroll type, and voluntary deductions

TABLE 56-3 Payroll Duties

Frequency	Duties
Upon assuming payroll responsibilities	Apply for an employer identification number (EIN) with Form SS-4 if the physician does not already have an EIN.
When a new employee is hired	Have the employee complete an Employee's Withholding Allowance Certificate (Form W-4) and Employment Eligibility Verification (Form I-9). Record the employee's name and Social Security number from the employee's Social Security card.
Every payday	Withhold federal income tax and state and local income taxes (if any). Withhold the employee's share of FICA taxes (for Social Security and Medicare). Record matching amount for the employer's share. Calculate how much the practice must pay for each employee's federal and state unemployment tax.
Monthly or biweekly (depending on your deposit schedule)	Deposit withheld income taxes, withheld and employer Social Security taxes, and withheld and employer Medicare taxes.
Quarterly (by April 30, July 31, October 31, and January 31)	File Employer's Quarterly Federal Tax Return (Form 941). With the return, pay any taxes that were not deposited earlier. Deposit federal unemployment tax, if over \$100.
At least once a year	Have all employees update their W-4 forms.
On or before January 31	Give employees their Wage and Tax Statements (Form W-2), which show total wages and various withheld taxes. File Employer's Annual Federal Unemployment (FUTA) Tax Return (Form 940) with tax amount due.
On or before February 28	File Transmittal of Wage and Tax Statements (Form W-3) along with the government's copies of the W-2 forms.

Form NHR New Hire and Independent Contractor Reporting Form

Rev. 01/2010
Massachusetts
Department of
Revenue

TO ENSURE ACCURACY, PRINT (OR TYPE) NEATLY IN UPPER-CASE LETTERS AND NUMBERS, USING A DARK, BALLPOINT PEN.

Employee Information

FIRST NAME*	MI	LAST NAME*
SOCIAL SECURITY NUMBER*		DATE OF HIRE OR REINSTATEMENT*
ADDRESS*		
CITY/TOWN*	STATE*	ZIP*
		+4(OPTIONAL)

IT'S THE LAW! - Massachusetts regulations require employers with 25 or more employees to report their new hires and independent contractors electronically.

For more information, go to www.mass.gov/dor and select the **For Businesses** tab located at the top of the page.

Employer Information

EMPLOYER IDENTIFICATION NUMBER*	
CORPORATE NAME*	
PAYROLL ADDRESS TO WHICH THE INCOME WITHHOLDING ORDER WILL BE SENT*	
PAYROLL ADDRESS (Continued)	
CITY/TOWN*	STATE*
	ZIP*
	+4(OPTIONAL)

NOTE: All fields on this form with an * are mandatory fields. Please ensure all information entered is legible and accurate prior to submitting the form to DOR.

Helpful Hint: Once you have completed your employer information, you may copy this form to save time when reporting future new hires and independent contractors.

Send Completed Form NHR to:

Massachusetts Department of Revenue, PO Box 55141, Boston, MA 02205-5141 or,
you may fax the completed form to 617-376-3262.

FIGURE 56-11 New hire and independent contract reporting (NHR) form.

Pay Schedule and Payroll Type On the payroll information sheet, list the employee's *pay schedule*, showing how often the employee is paid. Common pay schedules are weekly, biweekly, and monthly.

List the employee's payroll type—hourly wage, salary, or commission—on the payroll information sheet. An hourly wage is a set amount of money per hour of work. A salary is a set amount of money per pay period, regardless of the number of hours worked. A commission is a percentage of the amount an employee earns for the employer. Salespeople, for example, are often paid by commission.

Number of Dependents Record the number of dependents (people who depend on the employee for financial support who will be claimed by the employee). Dependents include a spouse, children, and other family members.

You can find the number of dependents on the Employee's Withholding Allowance Certificate (**Form W-4**), which should have been completed when the employee was hired (Figure 56-12). Remember, keep the completed W-4 forms in the physician's personnel file and update them annually.

Voluntary Deductions Voluntary deductions are those items not required by law to be deducted from the employee's

Form W-4 (2015)

Purpose. Complete Form W-4 so that your employer can withhold the correct federal income tax from your pay. Consider completing a new Form W-4 each year and when your personal or financial situation changes.

Exemption from withholding. If you are exempt, complete only lines 1, 2, 3, 4, and 7 and sign the form to validate it. Your exemption for 2015 expires February 16, 2016. See Pub. 505, Tax Withholding and Estimated Tax.

Note. If another person can claim you as a dependent on his or her tax return, you cannot claim exemption from withholding if your income exceeds \$1,050 and includes more than \$350 of unearned income (for example, interest and dividends).

Exceptions. An employee may be able to claim exemption from withholding even if the employee is a dependent, if the employee:

- Is age 65 or older,
- Is blind, or
- Will claim adjustments to income; tax credits; or itemized deductions, on his or her tax return.

The exceptions do not apply to supplemental wages greater than \$1,000,000.

Basic instructions. If you are not exempt, complete the **Personal Allowances Worksheet** below. The worksheets on page 2 further adjust your withholding allowances based on itemized deductions, certain credits, adjustments to income, or two-earners/multiple jobs situations.

Complete all worksheets that apply. However, you may claim fewer (or zero) allowances. For regular wages, withholding must be based on allowances you claimed and may not be a flat amount or percentage of wages.

Head of household. Generally, you can claim head of household filing status on your tax return only if you are unmarried and pay more than 50% of the costs of keeping up a home for yourself and your dependent(s) or other qualifying individuals. See Pub. 501, Exemptions, Standard Deduction, and Filing Information, for information.

Tax credits. You can take projected tax credits into account in figuring your allowable number of withholding allowances. Credits for child or dependent care expenses and the child tax credit may be claimed using the **Personal Allowances Worksheet** below. See Pub. 505 for information on converting your other credits into withholding allowances.

Nonwage income. If you have a large amount of nonwage income, such as interest or dividends, consider making estimated tax payments using Form 1040-ES, Estimated Tax for Individuals. Otherwise, you may owe additional tax. If you have pension or annuity income, see Pub. 505 to find out if you should adjust your withholding on Form W-4 or W-4P.

Two earners or multiple jobs. If you have a working spouse or more than one job, figure the total number of allowances you are entitled to claim on all jobs using worksheets from only one Form W-4. Your withholding usually will be most accurate when all allowances are claimed on the Form W-4 for the highest paying job and zero allowances are claimed on the others. See Pub. 505 for details.

Nonresident alien. If you are a nonresident alien, see Notice 1392, Supplemental Form W-4 Instructions for Nonresident Aliens, before completing this form.

Check your withholding. After your Form W-4 takes effect, use Pub. 505 to see how the amount you are having withheld compares to your projected total tax for 2015. See Pub. 505, especially if your earnings exceed \$130,000 (Single) or \$180,000 (Married).

Future developments. Information about any future developments affecting Form W-4 (such as legislation enacted after we release it) will be posted at www.irs.gov/w4.

Personal Allowances Worksheet (Keep for your records.)

A	Enter "1" for yourself if no one else can claim you as a dependent	A	_____
B	Enter "1" if: • You are single and have only one job; or • You are married, have only one job, and your spouse does not work; or • Your wages from a second job or your spouse's wages (or the total of both) are \$1,500 or less. 	B	_____
C	Enter "1" for your spouse . But, you may choose to enter "-0-" if you are married and have either a working spouse or more than one job. (Entering "-0-" may help you avoid having too little tax withheld.)	C	_____
D	Enter number of dependents (other than your spouse or yourself) you will claim on your tax return	D	_____
E	Enter "1" if you will file as head of household on your tax return (see conditions under Head of household above)	E	_____
F	Enter "1" if you have at least \$2,000 of child or dependent care expenses for which you plan to claim a credit	F	_____
G	Child Tax Credit (including additional child tax credit). See Pub. 972, Child Tax Credit, for more information. • If your total income will be less than \$65,000 (\$100,000 if married), enter "2" for each eligible child; then less "1" if you have two to four eligible children or less "2" if you have five or more eligible children. • If your total income will be between \$65,000 and \$84,000 (\$100,000 and \$119,000 if married), enter "1" for each eligible child		
H	Add lines A through G and enter total here. (Note. This may be different from the number of exemptions you claim on your tax return.) ►	H	_____

For accuracy, complete all worksheets that apply.

- If you plan to **itemize** or **claim adjustments to income** and want to reduce your withholding, see the **Deductions and Adjustments Worksheet** on page 2.
- If you are **single and have more than one job** or are **married and you and your spouse both work** and the combined earnings from all jobs exceed \$50,000 (\$20,000 if married), see the **Two-Earners/Multiple Jobs Worksheet** on page 2 to avoid having too little tax withheld.
- If **neither** of the above situations applies, **stop here** and enter the number from line H on line 5 of Form W-4 below.

Separate here and give Form W-4 to your employer. Keep the top part for your records.

Form W-4 Department of the Treasury Internal Revenue Service		Employee's Withholding Allowance Certificate		OMB No. 1545-0074
► Whether you are entitled to claim a certain number of allowances or exemption from withholding is subject to review by the IRS. Your employer may be required to send a copy of this form to the IRS.		2015		
1 Your first name and middle initial		3 ☐ Single ☐ Married ☐ Married, but withhold at higher Single rate. Note. If married, but legally separated, or spouse is a nonresident alien, check the "Single" box.		2 Your social security number

FIGURE 56-12 Employee's Withholding Allowance Certificate (W-4) is completed upon hire and updated annually.

paycheck. These include additional federal withholding taxes, contributions to a 401(k) retirement plan, and payments to a company health insurance plan. Employees who want additional federal taxes taken out of their paycheck will indicate this deduction on their W-4 form.

Gross Earnings

Gross earnings refers to the total amount of income earned before deductions, and this figure must be calculated for each employee as a first step in the payroll process.

Calculating Gross Earnings For every payroll period, use data from the payroll information sheet to compute each employee's gross earnings. For an hourly employee, use this equation:

$$\text{Hourly Wage} \times \text{Hours Worked} = \text{Gross Earnings}$$

An employee who earns \$12.50 per hour and works 35 hours, for example, has gross earnings of \$437.50 (\$12.50 × 35 hours) per week.

For a salaried employee, use the salary amount as the gross earnings for the pay period, no matter how many hours the

employee worked. An employee who earns a weekly salary of \$500, for example, receives that amount whether she worked 30, 40, or 50 hours during that week.

Fair Labor Standards Act The Fair Labor Standards Act primarily affects employees who earn hourly wages. It limits the number of hours they may work, sets their minimum wage, and regulates their overtime pay. It also requires the employer to record the number of hours they work, usually on a time card or in a time book.

For hourly employees, this act mandates payment of

- Time and a half (1½ times the normal hourly wage) for all hours worked beyond the normal 8 in a regular workday.
- Time and a half for all hours worked on the sixth consecutive day of the workweek.
- Twice the normal wage (double time) for all hours worked on the seventh consecutive workday.
- Double time, plus normal holiday pay, for all hours worked on a company-approved holiday.

The Fair Labor Standards Act also requires overtime payments for part-time hourly employees for every hour worked beyond the normal 8 in a day or 40 in a week.

Making Deductions

The law requires all employers to withhold money from employees' gross earnings to pay federal, state, and local (if any) income taxes and certain other taxes. In addition, employees may wish you to make certain voluntary deductions. For example, you might be asked to deduct an amount for child care, if the practice or hospital provides onsite child care. You also might deduct employee contributions to health insurance premiums.

You must deposit all employee deductions and employer payments into separate accounts, one for each deduction type. Accounts are typically set up for each type of deduction. The most common are **tax liability accounts** which are used to pay taxes to appropriate government agencies.

Income Taxes Enough money must be withheld to cover the employee's federal income tax for the pay period. You can determine this amount by finding the employee's number of exemptions (from Form W-4) and referring to the tax tables in *Circular E, Employer's Tax Guide*, published by the IRS. Consult the state and local tax tables for other income taxes.

FICA Taxes For **Federal Insurance Contributions Act (FICA)** tax, withhold from the employee's check half of the tax owed for the pay period. Pay the other half from the practice's accounts. The amount of FICA tax that funds Social Security differs from the amount that funds Medicare. Report these two amounts separately. Check IRS *Circular E* for the latest FICA tax percentages and level of taxable earnings.

Unemployment Taxes Federal unemployment tax is not a deduction from the employees' paychecks but rather is based on their earnings and paid by the employer. The **Federal**

Unemployment Tax Act (FUTA) requires employers to pay a percentage of each employee's income, up to a certain dollar amount. The percentage may be reduced if the employer also pays state unemployment taxes.

States calculate unemployment taxes differently. Some states tax employers and employees; others tax only employers. State unemployment tax usually varies with the employer's past employment record. Employers with few layoffs, such as physicians, have lower tax rates than those with many layoffs. To compute state unemployment tax, apply the assigned tax rate to each employee's earnings, up to a maximum for the calendar year. For details, consult your state unemployment insurance department.

Workers' Compensation Some states require employers to insure their employees against possible loss of income resulting from work-related injury, disability, or disease. Although state laws vary, they typically require doctors to carry this insurance with a state insurance fund or state-authorized private insurer. Usually, a medical practice's insurance agent will audit the payroll books annually and then issue a bill for the workers' compensation premium due.

Calculating Net Earnings

Add each employee's required and voluntary deductions together to determine the total deductions. Then, subtract the total deductions from the gross earnings to get the employee's **net earnings**, or take-home pay. Use the following equation:

$$\text{Gross earnings} - \text{Total deductions} = \text{Net earnings}$$

The exception to this rule is contributions the employee makes to the employer retirement plan, if available. When sponsored by an employer, as with a 401(k) account, these deductions are often taken before taxes are calculated, reducing the employee's taxable income, which encourages the employee to take part in these plans.

Preparing Paychecks

The way you prepare the practice's payroll will depend on the system the practice uses. In a small practice, you may write paychecks manually. In this case, write the check amount for the employee's net earnings and deduct the check amount from the office checkbook. Payroll also may be handled through electronic banking; see the *Points on Practice* feature.

If the practice uses a payroll service, you may supply time cards or payroll data to the service by mail or electronically. The service calculates all the deductions, prepares paychecks, and mails them to the practice for distribution.

No matter how paychecks are prepared, they should include information about how the check amount was determined. This information usually appears on the check stub. It should match the information on the employee earnings records and payroll register. Procedure 56-4, at the end of the chapter, explains the process for generating payroll.

Maintaining Employee Earnings Records

You need to keep an employee earnings record for each employee (Figure 56-13). When creating the record, list the employee's name, address, phone number, Social Security

Handling Payroll Through Electronic Banking

Most employees like to have their paychecks deposited automatically. The money is available on the day of deposit and no one has to worry about losing a paycheck, getting to the bank before it closes, or carrying a paycheck around. Also, employees still receive a check stub along with a notification of deposit, so they can track their earnings and deductions. Contact your bank for more information and specific procedures for setting up EFTS and electronic payroll.

Then, for each pay period, record the employee's gross earnings, individual deductions, net earnings, and related information. Properly completed earnings records show each employee's earning history.

Manual payroll preparation and related tasks may take an hour per week for each employee. To save time and provide

FIGURE 56-14 The payroll register is designed to summarize information about all employees and their earnings.

employees the convenience of having their paychecks automatically deposited, some practices handle payroll tasks electronically.

If you work in a relatively small practice, you may handle all payroll tasks in the office, using accounting or payroll software. If you work in a large practice, you may prepare payroll information on the computer and transmit it to an outside payroll service for processing. Depending on which system and software the practice has, you may use the computer to

- Create, update, and delete employee payroll information files.
- Prepare employee paychecks, stubs, and W-2 forms.
- Update and print employee earnings records.
- Update all appropriate bookkeeping records, such as the payroll ledger and general ledger, with payroll data.

To perform these payroll functions electronically, follow the specific instructions in the software manual or get instructions from the payroll service. Generally, you would follow these steps:

1. Select an option from the “Payroll” menu. Wait for the prompt and select the appropriate employee from the employee list.
2. Create a new employee file:
 - a. Enter employee name, address, SSN, marital status, pay schedule, number of dependents, payroll type, and voluntary deductions.
 - b. Print two copies—one for the employee and one for the personnel file.
3. Update employee payroll information after a life change such as change in marital status, birth of a child, change of address, or voluntary change in deductions:
 - a. Select “Update Employee File.”
 - b. Make required changes.
 - c. Print the form for the employee signature after he confirms information is correct.
 - d. Print two signed copies—one for the employee and one for the personnel file.

e. Payroll information must be correct and current. It should be updated yearly for each employee.

4. Delete an employee from payroll:
 - a. Select “Terminate Employee.”
 - b. Print a copy of the file before deleting it, as the employer is required to keep employee payroll records for 4 years.
5. Generate paychecks and paystubs:
 - a. Select the employee from the employee list.
 - b. Choose the “Print Paycheck” option.
 - c. Answer each prompt displayed (for example, hours worked).
 - d. From the payroll information entered previously, the program calculates the employee’s net earnings, generates a paycheck, and prints a pay stub with the appropriate information.
6. Create an employee earnings record:
 - a. Select “Creating Employee Earnings Record.”
 - b. Follow the prompts to enter the required information.
 - c. Depending on the software program used, this information may be updated automatically with each paycheck generated.

Select an option from the “Payroll” menu. Wait for the prompt; then select the appropriate employee from a list of employees.

▶ Calculating and Filing Taxes

LO 56.7

In many practices, administrative medical assistants set up tax liability accounts for money withheld from paychecks. These accounts are used to submit this money to appropriate agencies. Visit <http://www.irs.gov> for further information.

Setting Up Tax Liability Accounts

It is important to hold the money deducted from paychecks until it can be sent to the appropriate government agencies. Deductions from employees’ paychecks for federal, state, and local income taxes and FICA taxes, as well as employer

payments based on payroll, such as federal and state unemployment taxes, must be deposited until payment is due. For these accounts, choose a bank authorized by the IRS to accept federal tax deposits. If the practice makes other paycheck deductions, such as for workers' compensation or a 401(k) plan, other accounts are created and accurate records for this money must be maintained.

Each time you prepare paychecks, deposit the withheld money into the proper account as dictated by your practice. Record the deposited amounts as debits in the practice's checking account.

Understanding Federal Tax Deposit Schedules

You will probably deposit federal income taxes and FICA taxes (which together are known as employment taxes) on a quarterly, monthly, or biweekly (every-other-week) schedule. Every November, IRS personnel decide which deposit schedule your office should use for the next year.

If the IRS does not notify you about this matter, determine your deposit schedule based on the total employment taxes your office reported on the previous year's Employer's Quarterly Federal Tax Returns (Form 941). For example, if your office reported \$50,000 or less in employment taxes during the past year, you would make monthly employment tax deposits the present year. If your office reported more than \$50,000 during the past year, you would make semimonthly tax deposits.

Exceptions to the monthly or semimonthly tax deposit schedules are the \$500 rule and the \$100,000 rule. The \$500 rule applies to employers who owe less than \$500 in employment taxes during a tax period (such as a quarter). These employers do not have to make a deposit for that period. The \$100,000 rule applies to employers who owe \$100,000 or more in employment taxes on any one day during a tax period. These employers must deposit the tax by the next banking day after the day that ceiling is reached.

Submitting Federal Income Taxes and FICA Taxes

Since January 1, 2011, businesses must submit federal income taxes and FICA taxes to the IRS by electronic funds transfer (EFT), known as TAXLINK. If for any reason a check must be mailed, such as the office EFT process having not yet been completed, make the check payable to "Financial Agent." Put the practice EIN in the check's memo section and mail it to Financial Agent, Federal Tax Deposit Processing Center, in St. Louis, Missouri. If your office does not have electronic fund transfer capabilities, contact the office accountant or financial institution, who may be able to submit your tax liabilities for you (a fee is usually charged for this service).

If you work in a practice with a large payroll, you may need to make deposits every few days. In most practices, however, you will probably make deposits once a month. Then, every 3 months, a more complete accounting is required on a quarterly basis, which will be discussed in more detail a bit later in this chapter.

Submitting Federal Unemployment Tax Act (FUTA) and State Unemployment Tax Act (SUTA) Taxes

FUTA taxes provide money to workers who are unemployed. If the practice owes more than \$100 in federal unemployment tax at the end of the quarter, deposit the tax amount with an FTD Coupon (Form 8109). At the end of the year, file an Employer's Annual Federal Unemployment (FUTA) Tax Return (Form 940) with any final taxes owed (Figure 56-15).

Generally, an employer must pay FUTA taxes if employees' wages total more than \$1,500 in any quarter (3-month period) and if those employees are not seasonal or household workers. The FUTA tax, which is 6.2%, is applied to the first \$7,000 of income for a year.

Some states are also governed by a State Unemployment Tax Act (SUTA). These taxes are filed along with FUTA taxes. Make sure you know the laws governing unemployment taxes in your state.

Filing an Employer's Quarterly Federal Tax Return

Each quarter, file an Employer's Quarterly Federal Tax Return (Form 941) with the IRS (Figure 56-16). This tax return summarizes the federal income and FICA taxes (employment taxes) withheld from employees' paychecks.

As a general rule, you should file Form 941 at the nearest IRS office by the last day of the first month after the quarter ends. If the practice has deposited all taxes on time, you have an additional 10 days after the due date to file.

Handling State and Local Income Taxes

Send withheld state and local income taxes to the proper agencies, using their forms, procedures, and schedules. If required, prepare quarterly or other tax forms for your state or local agency. If you are unsure of how often to submit these forms and taxes, you can visit your state website or the IRS website at <http://www.irs.gov>.

Filing Wage and Tax Statements

After the end of each year, file a Wage and Tax Statement (**Form W-2**) with the appropriate federal, state, and local government agencies for each employee who had federal income and FICA taxes withheld during the previous year (Figure 56-17). Also, supply copies of Form W-2 to each employee.

Form W-2 shows the employee's total taxable income for the previous year. It also shows the exact amount of federal income taxes and FICA taxes (for Social Security and Medicare) withheld, along with the amounts of state and local taxes withheld (if any).

Along with the W-2 forms, submit Form W-3, a Transmittal of Wage and Tax Statements (Figure 56-18). This form lists the employer's name, address, and EIN and summarizes the amount of all employees' earnings and the federal income taxes and FICA taxes withheld.

Form **940 for 2014:** Employer's Annual Federal Unemployment (FUTA) Tax Return OMB No. 1545-0028

Type of Return
(Check all that apply.)

☐ a. Amended

☐ b. Successor employer

☐ c. No payments to employees in 2014

☐ d. Final: Business closed or stopped paying wages

Instructions and prior-year forms are available at www.irs.gov/form940.

Read the separate instructions before you complete this form. Please type or print within the boxes.

Part 1: Tell us about your return. If any line does NOT apply, leave it blank.

1a If you had to pay state unemployment tax in one state only, enter the state abbreviation . 1a

1b If you had to pay state unemployment tax in more than one state, you are a multi-state employer 1b ☐ Check here. Complete Schedule A (Form 940).

2 If you paid wages in a state that is subject to CREDIT REDUCTION 2 ☐ Check here. Complete Schedule A (Form 940).

Part 2: Determine your FUTA tax before adjustments for 2014. If any line does NOT apply, leave it blank.

3 Total payments to all employees 3

4 Payments exempt from FUTA tax 4

Check all that apply: 4a ☐ Fringe benefits 4c ☐ Retirement/Pension 4e ☐ Other

4b ☐ Group-term life insurance 4d ☐ Dependent care

5 Total of payments made to each employee in excess of \$7,000 5

6 Subtotal (line 4 + line 5 = line 6) 6

7 Total taxable FUTA wages (line 3 - line 6 = line 7) (see instructions) 7

8 FUTA tax before adjustments (line 7 x .006 = line 8) 8

Part 3: Determine your adjustments. If any line does NOT apply, leave it blank.

9 If ALL of the taxable FUTA wages you paid were excluded from state unemployment tax, multiply line 7 by .054 (line 7 x .054 = line 9). Go to line 12 9

10 If SOME of the taxable FUTA wages you paid were excluded from state unemployment tax, OR you paid ANY state unemployment tax late (after the due date for filing Form 940), complete the worksheet in the instructions. Enter the amount from line 7 of the worksheet 10

11 If credit reduction applies, enter the total from Schedule A (Form 940) 11

Part 4: Determine your FUTA tax and balance due or overpayment for 2014. If any line does NOT apply, leave it blank.

12 Total FUTA tax after adjustments (lines 8 + 9 + 10 + 11 = line 12) 12

13 FUTA tax deposited for the year, including any overpayment applied from a prior year 13

14 Balance due (If line 12 is more than line 13, enter the excess on line 14.)

- If line 14 is more than \$500, you must deposit your tax.
- If line 14 is \$500 or less, you may pay with this return. (see instructions) 14

15 Overpayment (If line 13 is more than line 12, enter the excess on line 15 and check a box below.) 15

► You **MUST** complete both pages of this form and **SIGN** it. Check one: ☐ Apply to next return. ☐ Send a refund.

Form W-3 Transmittal of Wage and Tax Statements 2015

Department of the Treasury
Internal Revenue Service

Send this entire page with the entire Copy A page of Form(s) W-2 to the Social Security Administration (SSA). Photocopies are not acceptable. Do not send Form W-3 if you filed electronically with the SSA. Do not send any payment (cash, checks, money orders, etc.) with Forms W-2 and W-3.

Reminder

Separate instructions. See the 2015 General Instructions for Forms W-2 and W-3 for information on completing this form. Do not file Form W-3 for Form(s) W-2 that were submitted electronically to the SSA.

Purpose of Form

A Form W-3 Transmittal is completed only when paper Copy A of Form(s) W-2, Wage and Tax Statement, is being filed. Do not file Form W-3 alone. All paper forms **must** comply with IRS standards and be machine readable. Photocopies are **not** acceptable. Use a Form W-3 even if only one paper Form W-2 is being filed. Make sure both the Form W-3 and Form(s) W-2 show the correct tax year and Employer Identification Number (EIN). Make a copy of this form and keep it with Copy D (For Employer) of Form(s) W-2 for your records. The IRS recommends retaining copies of these forms for four years.

E-Filing

The SSA strongly suggests employers report Form W-3 and Forms W-2 Copy A electronically instead of on paper. The SSA provides two free e-filing options on its Business Services Online (BSO) website:

- **W-2 Online.** Use fill-in forms to create, save, print, and submit up to 50 Forms W-2 at a time to the SSA.
- **File Upload.** Upload wage files to the SSA you have created using payroll or tax software that formats the files according to the SSA's *Specifications for Filing Forms W-2 Electronically (EFW2)*.

W-2 Online fill-in forms or file uploads will be on time if submitted by March 31, 2016. For more information, go to www.socialsecurity.gov/employer. First time filers, select "Go to Register"; returning filers select "Go To Log In."

When To File

Mail Form W-3 with Copy A of Form(s) W-2 by February 29, 2016.

Where To File Paper Forms

Send this entire page with the entire Copy A page of Form(s) W-2 to:

**Social Security Administration
Data Operations Center
Wilkes-Barre, PA 18769-0001**

Note. If you use "Certified Mail" to file, change the ZIP code to "18769-0002." If you use an IRS-approved private delivery service, add "ATTN: W-2 Process, 1150 E. Mountain Dr." to the address and change the ZIP code to "18702-7997." See Publication 15 (Circular E), Employer's Tax Guide, for a list of IRS-approved private delivery services.

For Privacy Act and Paperwork Reduction Act Notice, see the separate instructions.

Cat. No. 10159Y

FIGURE 56-18 Submit the Transmittal of Wage and Tax Statements (Form W-3) with the W-2 forms.

PROCEDURE 56-1 Preparing a Travel Expense Report

WORK // DOC

(Imagine that you have just attended the latest AAMA or AMT annual conference. Research the price of airfare from your locale to the city of the conference. Determine registration and other costs. Use these figures to perform the procedure.)

Procedure Goal: To obtain reimbursement or account for pre-approved travel funds and to provide documentation of expenses for the medical office

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Travel expense report form, pen, receipts, conference web information, and a calculator

Method:

1. Ensure that your travel received prior approval.

RATIONALE: *Without prior approval, your expenses may be denied.*

2. Save receipts from the event.
3. Complete the personal identifying information on the form.
4. Insert the purpose of the travel, location, dates, and number of days.
5. Place the amounts as labeled in the expense table.
6. Total the amounts.

7. Check the appropriate box to indicate if you missed work and the dates and total number of days.
8. Sign and date the form.
9. Attach receipts (generally, original receipts are submitted; keep copies for your own records).

RATIONALE: *Without receipts, the expenses will not be reimbursed.*

10. Submit the completed form and receipts.

PROCEDURE 56-2 Preparing an Agenda

Procedure Goal: To facilitate a meeting's organization and focus by providing a list of meeting topics, the name of the person reporting, and the order in which each topic will be addressed

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Paper and pen or computer, copy machine, and minutes from last meeting

Method:

1. Approximately 1 week before the meeting, e-mail or post a memo to staff, offering them an opportunity to add items to the agenda. This is referred to as a *Call for Agenda Items*.

RATIONALE: *Allows an opportunity for all staff members to suggest items for discussion.*

2. Place the following on top of the form used to create the agenda:
 - Name of the practice
 - Site name, if the practice has more than one location
 - Title: *Staff Meeting Agenda*
 - Date and time the meeting is scheduled to begin and end
3. Many offices have standing topics that go on the agenda every month; examples are
 - Introduction of new staff members.
 - Approval of minutes, if formal minutes are kept.
 - Staff news (promotions, birthdays, weddings, births, and so on).

- Quality assurance report.
- Policy and procedure updates.
- Committee reports.
- Report from individuals who have attended a conference.

RATIONALE: *Consistency in meeting format ensures that items are not forgotten.*

4. Review the minutes from the previous meeting to determine any topics that required action with the person responsible. List these on the agenda under *Old Business*.
5. Add topics obtained from the *Call for Agenda Items* and any new topics the manager wishes to discuss. List these under *New Business*.
6. Add *Other* on the agenda to allow announcements or other brief information.
7. Place the date and time of the next meeting at the end of the agenda.

RATIONALE: *Advance notice allows staff members to plan other meetings and events around previously scheduled items.*

8. At least 1 week prior to the meeting, inform and verify persons on the agenda who will present a topic at the meeting.

RATIONALE: *Advance notice ensures that those presenting topics will be prepared.*

9. Send agenda to staff members prior to the meeting.
10. Make copies available at the staff meeting.

PROCEDURE 56-3 Completing an Incident Report

WORK // DOC

Procedure Goal: To provide documentation of an adverse incident or potential risk in order to facilitate investigation, correction, and avoidance of future occurrences

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Paper, a pen, and an incident report form

Method:

1. If anyone is injured, make sure initial first aid and appropriate steps are taken to help the injured person.

RATIONALE: *The injured person must be taken care of prior to completing any paperwork.*

2. Interview the person to whom the incident occurred, gathering the facts required for the incident report, including contact information.
RATIONALE: *The injured person's statement should be in her own words, clarifying information as needed.*
3. Interview witnesses, gathering the facts required for the incident report, including contact information.

RATIONALE: *Witnesses can add information to the injured person's statement of how the incident occurred.*

4. Ensure that the information is complete.
5. Transfer the information to the incident report form.
6. Review the form for accuracy and clarity.
7. Submit the form to the appropriate supervisor.

PROCEDURE 56-4 Generating Payroll

WORK // DOC

Procedure Goal: To handle the practice's payroll efficiently and accurately for each pay period

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Employees' time cards, employees' earnings records, payroll register, IRS tax tables, and check register

Method:

1. Calculate the total regular and overtime hours worked, based on the employee's time card. Enter those totals under the appropriate headings on the payroll register.
2. Check the pay rate on the employee earnings record. Multiply the hours worked (including any paid vacation or paid holidays, if applicable) by the rates for regular time and overtime (time and a half or double time). This yields gross earnings.
3. Enter the gross earnings under the appropriate heading on the payroll register. Subtract any nontaxable benefits, such as healthcare or retirement programs.
4. Using IRS tax tables and data on the employee earnings record, determine the amount of federal income tax to withhold based on the employee's marital status and number of exemptions. Also, compute the amount

of FICA tax to withhold for Social Security (6.2%) and Medicare (1.45%).

5. Following state and local procedures, determine the amount of state and local income taxes (if any) to withhold based on the employee's marital status and number of exemptions.
6. Calculate the employer's contributions to FUTA and to the state unemployment fund, if any. Post these amounts to the employer's account.
7. Enter any other required or voluntary deductions, such as health insurance or contributions to a 401(k) fund.
8. Subtract all deductions from the gross earnings to get the employee's net earnings.
9. Enter the total amount withheld from all employees for FICA under the headings for Social Security and Medicare. Remember that the employer must match these amounts. Enter other employer contributions, such as for federal and state unemployment taxes, under the appropriate headings.
10. Fill out the check stub, including the employee's name, the date, the pay period, gross earnings, all deductions, and net earnings. Make out the paycheck for the net earnings.
11. Deposit each deduction in a tax liability account.

LEARNING OUTCOMES

- 56.1 Explain the basic organizational designs of the medical office and the relationship of the physician and the medical assistant with the practice manager and direct supervisors.**

KEY POINTS

In a physician-owned medical practice, the medical assistant will often report directly to the practice manager. In a company-owned practice, the medical assistant will often report to the medical director. Regardless of the practice's organizational design, the medical assistant should always know the office chain of command and who her direct supervisor is and should consistently follow the chain of command as outlined in the organizational chart and the office policies and procedures manual.

LEARNING OUTCOMES	KEY POINTS
56.2 Describe the responsibilities of the practice manager.	The practice manager's job description may change from practice to practice, but common responsibilities include creating, updating, and maintaining the office policies and procedures manual; making sure all licenses and certifications necessary for all healthcare providers are up-to-date; and ensuring that all necessary contracts with payers and other providers are current. The practice manager is also in charge of the practice's finances and budget, including overseeing the office petty cash fund. Exceptional communication and interpersonal skills are required. On any given day, the manager may be communicating with staff, patients, healthcare providers, hospitals, insurers, vendors, contractors, government agencies, bankers, other employers, educators, attorneys, and community organizations. The manager also evaluates and purchases equipment and systems that fit the practice's needs and budget, facilitates the installation and staff training, and then oversees the ongoing operations. Other managerial functions include ensuring the availability of mailing and shipping services, inventory and supply purchases, and appropriate market and public relation strategies, which may include websites, brochures, and community event sponsorship.
56.3 Summarize the basic human resources functions in practice management.	The <i>human resources role</i> refers to how the practice manages employees and deals with elements of hiring, orienting, and training employees and terminating employees when necessary. Understanding the laws, acts, and regulations surrounding employment is also a large part of the human resources aspect of the practice manager's role.
56.4 Distinguish four of the possible traits of someone with leadership skills and the importance of these skills to the healthcare team.	Any of the following traits may be attributable to a leader: a desire to achieve both personal and organizational goals; confidence that is based on a good understanding of the situation at hand; the ability to be a team member and influence other members of the team to accomplish stated goals; excellent communication skills; the ability and willingness to accommodate change; integrity; the willingness to accept responsibility; the realization that goals are achieved best through the efforts of many; and the giving of genuine recognition to others who assist in achieving goals. All of these items and the ability to be a leader are important in a medical assistant as a healthcare team member because, when the office members work together with the common goal of caring for their patients, the result is excellent patient care.
56.5 Compare risk management and quality assurance in a medical facility.	The term <i>risk management (RM)</i> is defined as a plan and processes that continually identify, assess, correct, and monitor functions of the medical office to prevent negative outcomes and minimize risk exposure and consequent liability. When an incident does occur, an incident report is completed to track the cause of the incident to minimize future risk. <i>Quality assurance (QA)</i> consists of procedures that ensure that the services provided in the medical practice meet or exceed the requirements and standards.

LEARNING OUTCOMES

56.6 Calculate an employee's gross earnings, deductions, and net earnings for a pay period.

56.7 Describe tax forms commonly used in the medical office and the purpose of the office tax liability account.

KEY POINTS

To calculate an employee's gross earnings, multiply the hours worked by the hourly rate. Using state, local, and federal tax guidelines, calculate the employee's tax deductions. Add to these any voluntary deductions and subtract the total deductions to obtain the employee's net earnings. Using the employee payroll record containing the employee's name, address, SSN, and number of exemptions, record the employee's gross earnings, deductions (including mandatory and voluntary deductions), and net paycheck.

Tax forms used in a medical practice include, but are not limited to, W-2, W-3, and W-4 forms; NHR forms; I-9s; quarterly federal tax forms; wage and tax statements; and FUTA and SUTA forms. The practice liability account is set up to hold the money deducted from employees' paychecks until the funds can be appropriately disbursed to government agencies. There may be separate accounts for federal and state taxes as well as unemployment and retirement funds. Record the tax amounts deposited in the liability account as debits in the practice's checking account.

Recall Cindy Chen from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. What questions would be appropriate to ask Cindy when interviewing her for the position?
2. If she is hired, other staff members may also know her medical status. How should this be best handled by the practice? By Cindy?

E X A M P R E P A R A T I O N Q U E S T I O N S

1. (LO 56.1) In most medical practices, the medical assistant will work under the supervision of
 - a. The physician
 - b. The physician assistant
 - c. The nurse practitioner
 - d. The staff nurse
 - e. Any of these, depending on the practice structure
2. (LO 56.2) The document that is the backbone of the medical practice is its
 - a. HIPAA manual
 - b. Employee manual
 - c. Policies and procedures manual
 - d. SDS binder
 - e. OSHA guidelines
3. (LO 56.2) The practice manager is responsible for which of the following tasks?
 - a. Licenses, certifications, and contract updates
 - b. Budgets and financial planning
 - c. Petty cash management
 - d. Schedule and travel for physicians and employees
 - e. All of these
4. (LO 56.3) Which act does *not* come under the heading of human resources?
 - a. EEOC
 - b. ADA
 - c. FMLA
 - d. ECOA
 - e. Fair Labor Standards Act

5. (LO 56.3) Which of the following questions cannot be asked during an interview?
 - a. Do you have reliable transportation?
 - b. Do you have small children at home?
 - c. Are you capable of performing the duties listed on the job description?
 - d. We require a certification for our medical assistants; are you certified?
 - e. Our hours are 8:00 a.m.–4:30 p.m. and one Saturday a month from 8:00 a.m.–1:00 p.m. on a rotating schedule; can you be available for this schedule?
6. (LO 56.4) Why are goals important in building a team?
 - a. Goals keep team members busy
 - b. Goals keep each person focused solely on his or her own job
 - c. Creating goals keeps supervisors busy
 - d. Goals increase understanding of expectations
 - e. None of these
7. (LO 56.5) There are five steps to the improvement process. Which one implements the plan?
 - a. Identification
 - b. Assessment
 - c. Correction
 - d. Monitoring
 - e. Reevaluation
8. (LO 56.5) When is an incident report required?
 - a. Only if an employee is injured while working
 - b. Only if a patient is hurt because of employee error
 - c. Only if a patient is hurt through no fault of the office staff
 - d. For any adverse incident with risk of liability
 - e. For any adverse incident with no risk of liability
9. (LO 56.6) Which tax form is more commonly known as the I-9?
 - a. Form NHR
 - b. Employment Eligibility and Verification
 - c. Employee's Withholding Allowance Certificate
 - d. Transmittal of Wage and Tax Statements
 - e. Employee Wage and Tax Statement
10. (LO 56.7) Which tax provides for unemployment benefits?
 - a. FUTA
 - b. SUTA
 - c. FICA
 - d. State and local tax
 - e. EFT

S O F T S K I L L S S U C C E S S

Recall Cindy Chen from the case study at the beginning of the chapter.

1. As an intern, Cindy went through a “mini” employee orientation. Malik explained to her that if she is hired, she will report directly to him. She will be expected to complete a 90-day probationary period, during which she will be expected to follow all office protocol and continue her learning process. Additionally, during this time, either the office or she can part ways if the employment does not appear to be a good fit for either party. He also explained that all employees are expected to cross-train to allow coverage for all positions during illness or vacation. Although Cindy loves the clinical aspect of the office, she understands she should take advantage of any learning opportunities that come her way. How do you think she should respond?
2. Malik asks Cindy if she understands the concept of the office petty cash fund, and Cindy states, “Yes”; she used it during her externship to purchase some tissues for the office when they ran out. Malik then asks her what she would do if she realized the petty cash fund appeared to be “short.”

Emergency Preparedness

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Mohammad Nassar	5/17/20XX	Animal dander
PATIENT INFORMATION	Attending	MRN	Other Information
	Elizabeth H. Williams, MD	423-90-687	No record of current influenza vaccination

Mohammad Nassar, a 15-year-old male, is a returning patient. His mother brings him to the office today with flu-like symptoms, including high fever and chills, muscle aches, and coughing. He has a known past medical history of asthma, which has been relatively stable on a new maintenance dose of albuterol extended-release tablets 8 mg twice a day. Mohammad states that he aches all over and feels like he is “freezing.” He

© David Sacks/Getty Images

is the eighth person this morning who has come in with flu-like symptoms. The other seven patients tested positive on a rapid test for influenza type A. Mohammad's rapid influenza screening test is positive. He is now the eighth positive case this morning. The office manager informs you that the local health department notified the office that there is a severe regional

outbreak of a novel type of influenza A.

Keep Mohammad (and his mother) in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 57, you will be able to:

- 57.1** Discuss the importance of first aid during a medical emergency.
- 57.2** Identify items found on a crash cart.
- 57.3** Recognize various accidental emergencies and how to deal with them.
- 57.4** List common illnesses that can result in medical emergencies.
- 57.5** Identify less common illnesses that can result in medical emergencies.
- 57.6** Discuss your role in caring for people with psychosocial emergencies.
- 57.7** Carry out the procedure for calming a patient who is under extreme stress.
- 57.8** Discuss ways to educate patients about how to prevent and respond to emergencies.
- 57.9** Illustrate your role in responding to natural disasters and pandemic illness.
- 57.10** Discuss your role in responding to acts of bioterrorism.

KEY TERMS

- | | |
|--|-------------------------------|
| automated external defibrillator (AED) | hematoma |
| bioterrorism | hyperglycemia |
| cerebrovascular accident (CVA) | hypoglycemia |
| concussion | hypovolemic shock |
| contusion | palpitations |
| crash cart | septic shock |
| dehydration | shelter-in-place |
| epistaxis | splint |
| hematemesis | sprain |
| | strain |
| | ventricular fibrillation (VF) |

- I.C.13** List principles and steps of professional/provider CPR
- I.C.14** Describe basic principles of first aid as they pertain to the ambulatory healthcare setting
- I.P.13** Perform first aid procedures for:
 - (a) bleeding
 - (b) diabetic coma or insulin shock
 - (c) fractures
 - (d) seizures
 - (e) shock
 - (f) syncope
- I.A.1** Incorporate critical thinking skills when performing patient assessment
- I.A.2** Incorporate critical thinking skills when performing patient care
- III.P.2** Select appropriate barrier/personal protective equipment (PPE)
- III.P.8** Perform wound care
- III.P.9** Perform dressing change
- X.C.7** Define:
 - (d) Good Samaritan Act(s)
- X.C.13** Define the following medical legal terms:
 - (n) Good Samaritan laws
- XII.C.6** Discuss protocols for disposal of biological chemical materials
- XII.C.8** Identify critical elements of an emergency plan for response to a natural disaster or other emergency
- XII.P.4** Participate in a mock exposure event with documentation of specific steps
- XII.A.1** Recognize the physical and emotional effects on persons involved in an emergency situation
- XII.A.2** Demonstrate self-awareness in responding to an emergency situation

2. Anatomy and Physiology

- c. Identify diagnostic and treatment modalities as they relate to each body system

9. Clinical Procedures

- b. Obtain vital signs, obtain patient history, and formulate chief complaint
- g. Recognize and respond to medical office emergencies
- j. Make adaptations with patients with special needs

► Introduction

Emergencies of all types can occur when you are working as a medical assistant. Patients may come to your facility with an acute illness or injury. You may have to handle phone calls from patients with urgent physical or psychological problems. You might even experience a disaster—from a simple office fire to a bomb threat or bioterrorism. As a medical assistant, you must be prepared to determine the level of urgency and handle any emergency that arises. Remember to stay calm and think through each situation in order to respond appropriately and create the best outcome.

► Understanding Medical Emergencies

LO 57.1

A medical emergency is any situation in which a person suddenly becomes ill or sustains an injury that requires immediate

help by a healthcare professional. Your prompt action in a medical emergency could prevent permanent disability or even death.

As a medical assistant, you may see life-threatening medical emergencies in the healthcare setting. For example, a patient in the waiting room may have chest pains that could indicate a heart attack is imminent. You also may see emergencies that are not life-threatening, such as a coworker sustaining a minor injury on the job. And you could encounter emergencies outside the office. For example, a family member might cut a finger while using a kitchen knife or a restaurant patron might choke on a piece of food. Your quick response is vital in all of these situations.

In or out of the office, a medical emergency may require you to perform first aid. First aid is the immediate care given to someone who is injured or suddenly becomes ill, before complete medical care can be obtained. Prompt and appropriate first aid can

- Save a life.
- Reduce pain.

- Prevent further injury.
- Reduce the risk of permanent disability.
- Increase the chance of early recovery.

Because most emergencies do not occur in a medical office, your role in patient education is critical. The more you teach patients about first aid and the proper way to respond to emergencies, the better equipped they will be to handle accidental injuries and illnesses. You also should make patients aware of Good Samaritan laws. These laws protect people who respond, in good faith, to medical emergencies but have no medical training. Every state in the United States has Good Samaritan laws or regulations.

► Preparing for Medical Emergencies

LO 57.2

How prepared you are for an emergency can mean the difference between life and death for a patient. You must be able to perform procedures quickly and correctly. Keeping your skills up-to-date will enable you to handle medical emergencies effectively.

Just as important is your ability to ensure that the medical office where you work is ready to handle whatever emergencies arise. This preparedness will depend on your own organizational skills and knowledge of community resources.

Preparing the Office

First, establish with the doctor which duties are expected of you and of other office personnel in case of an emergency and determine the available resources. One of your most important allies will be the local emergency medical services (EMS) system. An EMS system is a network of qualified emergency services personnel who use community resources and equipment to provide emergency care to victims of injury or sudden illness.

Posting Emergency Telephone Numbers Although the local EMS system's telephone number is 911 in most parts of the country, some areas may not have 911 service. Post the area's EMS system telephone number at every telephone and on the **crash cart** (the rolling cart of emergency supplies and equipment) or first-aid tray. Every office employee should know this number. If the community has no EMS system, post the telephone number of the local ambulance or rescue squad. You also should post the telephone numbers of the nearest fire company, police station, poison control center, women's shelter, rape hotline, and drug and alcohol center.

When you call EMS for medical assistance and transport, speak clearly and calmly to the dispatcher and be prepared to provide the following information:

- Your name, telephone number, and location
- Nature of the emergency
- Number of people in need of help
- Condition of the injured or ill patient(s)
- Summary of the first aid that has been given
- Directions on how to reach the location of the emergency

Do not hang up until the dispatcher gives you permission to do so.

Common Emergency and First-Aid Supplies

The crash cart or tray contains basic drugs, supplies, and equipment for medical emergencies. Most crash carts also contain a first-aid kit with supplies for managing minor injuries and ailments. Table 57-1 lists the usual items in a first-aid kit. The actual contents of the crash cart may vary slightly from practice to practice. Become familiar with these contents and know where they are located in the office. Procedure 57-1, at the end of this chapter, describes how to check and restock essential crash cart items.

TABLE 57-1 Contents of a First-Aid Kit

Absorbent compress bandages (sterile)
Adhesive bandages (assorted sizes)
Adhesive tape
Airway or breathing barrier
Analgesics, such as acetaminophen
Antiseptic solution or spray
Antiseptic wipes
Aspirin (81 mg)
Calamine lotion
Chemical cold packs
Diphenhydramine (Benadryl®)
Disposable gloves
Elastic bandages in various sizes
Emergency blanket
First-aid book or information card
Gauze pads (sterile)
Glucose tablets or sugar source
Hand sanitizer
Personal protective equipment (PPE): gloves, mask, and goggles or face shield, gown, shower cap, booties, pocket mask, or mouth shield
Plastic bags
Premoistened towelettes or hand cleaner
Roller bandages
Scissors
Splints in various sizes
Sterile gauze pads in various sizes
Sterile rolls of gauze
Sterile saline solution
Sunscreen
Thermometer (with extra batteries if digital)
Triangular bandage
Tweezers
Waterproof flashlight with extra batteries

Guidelines for Handling Emergencies

A medical emergency requires you to take certain steps. You are not responsible for diagnosing or providing medical care other than first aid. You are expected, however, to note the presence of serious conditions that threaten the patient’s life and to take appropriate action, performing only those procedures you have been trained to perform.

Patient Emergencies Assess the situation and surroundings to determine whether it is safe for you to assist. If safe, don the appropriate PPE, such as gloves. Next, do an initial assessment to detect and immediately correct any life-threatening circulation, airway, and breathing problems. Correcting life-threatening problems is essential to survival. The initial assessment has six steps:

- 1. Form a general impression of the patient.
- 2. Determine the patient’s level of responsiveness.
- 3. Assess the circulation (compressions or the need for them if no pulse detected), airway, and breathing status of the patient, sometimes referred to as the CABs.
- 4. Determine the priority or urgency of the patient’s condition.
- 5. Conduct a focused exam.
- 6. Document a history.

Procedure 57-2, at the end of this chapter, provides guidelines for performing these six steps.

Telephone Emergencies Sometimes, a patient or a patient’s family member calls the medical office with an emergency. If you are responsible for handling telephone calls, be prepared to triage the injuries by phone. Triage is the classification of injuries according to severity, urgency of treatment, and place for treatment.

To handle emergency calls, follow the practice’s telephone triage protocols. For example, if a parent calls to say her daughter has broken her arm and the child’s bone is visible, tell her to call the local EMS system for immediate care and transport to the hospital. If, however, a parent calls to say her son swallowed half a bottle of baby bath, tell her to remain calm and give her the telephone number of the poison control center. Depending on circumstances, you may offer to make the necessary phone call yourself.

Adhere to the following general guidelines in any emergency situation:

- Stay calm.
- Reassure the patient.
- Act in a confident, organized manner.

Personal Protection Whenever you administer first aid and emergency treatment, try to reduce or eliminate the risk of exposing yourself and others to infection. Follow standard precautions and assume that all blood and other body fluids are infected with bloodborne pathogens. To protect yourself and others, take the following basic precautions.

- Include PPE in all first-aid kits (gloves, goggles, mask, gown, cap, and booties).
- Include a pocket mask or mouth shield for rescue breathing.
- Use PPE appropriate to the patient’s condition. (See Table 57-2 for examples of PPE to use in various emergency situations.)
- Wear gloves if you expect hand contact with blood, other body fluids, or mucous membranes.
- If you have any cuts or lesions, wear PPE over the affected area.
- When in doubt, wear more PPE than you may think is called for.
- If blood or other body fluids splash into your eyes, nose, or mouth, flush the area with water as soon as possible.
- Wash your hands thoroughly with soap and water after removing the gloves.
- Wash other skin surfaces that have come in contact with blood or other body fluids.
- Do not touch your mouth, nose, or eyes and do not eat or drink after providing emergency care until you have washed your hands thoroughly.
- If you have been exposed to blood or other body fluids, be sure to tell your supervisor or healthcare practitioner. You may need postexposure treatment.

Documentation Properly document all office emergencies in the patient’s chart. Be sure to include your assessment, the treatment given, and the patient’s response. If the patient was transported to another facility, record the location.

TABLE 57-2 Personal Protective Equipment for Emergencies		
Equipment	Conditions for Use	Sample Emergencies Requiring Equipment
Gloves	Chance of contact with blood or other body secretion or excretion during emergency	Open wound, eye trauma
Goggles and mask or face shield and possible head cover	Chance of blood or other body secretion or excretion being splattered, coughed, or sprayed onto the mucus membranes of the eyes, mouth, or nose	Bleeding, vomiting, most emergency care for small children (because of squirming)
Gown and possibly booties	Chance of contact with excessive bleeding or secretion and excretion	Childbirth, severe nosebleed
Pocket mask or mouth shield	Needed for CPR or rescue breathing	Heart attack (MI), respiratory arrest

► Accidental Injuries

LO 57.3

No matter where you encounter an emergency, your knowledge and certifications should enable you to provide first aid for the patient until a physician or EMT arrives. To help you become familiar with how to handle various emergency situations, the following sections present accidental injuries, common illnesses, and less common illnesses.

Bites and Stings

Dog and cat bites and bee, wasp, and hornet stings are fairly common. Less common are snakebites and spider bites, which you are more likely to encounter in certain parts of the country, such as Florida or the Southwest, than in other areas.

Animal Bites An animal bite may bruise the skin, tear it, or leave a puncture wound. A wound that breaks the skin should be seen by a doctor and will need to be reported to the police, animal control officer, and local health department. If the animal can be found, it should be checked for rabies. Then, depending on the animal's rabies vaccination status, the animal may need to be quarantined. If the animal is a probable carrier of rabies and cannot be found, depending on the extent of the injury, the doctor may administer rabies immunoglobulin and rabies vaccination to the patient as a precaution.

Dogs, cats, skunks, squirrels, raccoons, bats, and foxes are more likely to carry rabies than are other animals. Hamsters, gerbils, guinea pigs, and mice are rarely infected by the rabies virus.

Human bites can raise concerns about transmitting the human immunodeficiency virus (HIV) or hepatitis B virus. HIV can be transmitted only if the bite breaks the skin and if the biter has bleeding gums. Hepatitis B virus may be transmitted by a human bite that punctures the skin. In this case, a series of three injections is required to immunize against hepatitis B.

Immediate care for bites calls for washing the area thoroughly with antiseptic soap and water. Apply a dry, sterile dressing. If the wound is bleeding profusely or spurting blood, apply pressure to the wound and seek medical attention. The healthcare practitioner will treat the wound and administer tetanus toxoid if the patient has not received it in the last 5 to 10 years.

Insect Stings Insect stings are merely a nuisance to most patients. The site of the sting can become red, swollen, itchy, and painful. If the patient was stung by a honeybee, you must first remove the stinger because it still has the ability to release venom. Remove the stinger by scraping the skin with a credit card or other flat, hard, sharp object. Be careful not to release more venom. Avoid using your fingers or tweezers because squeezing the stinger may force more venom into the wound.

(If you cannot remove the stinger, call the physician.) Wash the skin with soap and water. After the stinger is removed, apply ice to the site, 10 minutes on and 10 minutes off, to reduce the pain and swelling.

A sting can be deadly to a patient who is allergic to the insect venom because anaphylaxis can develop. The symptoms of and treatment for anaphylaxis are described later in this chapter.

Snakebites Poisonous snakes in the United States include rattlesnakes, water moccasins (or cottonmouths), copperheads, and coral snakes. Because snakes are cold-blooded, they often lie on rocks to warm themselves. Most bites occur when a person steps onto, sits down on, or reaches over or between rocks where a snake is sunning itself.

The bites of most poisonous snakes produce similar symptoms: one or two puncture marks, pain, and swelling at the site; rapid pulse; nausea; vomiting; and sometimes unconsciousness and seizures. If possible, get a description of the snake so that the EMS team or the hospital can procure the proper antivenin (a substance that counteracts the snake poison) ahead of time. Snakebites are dangerous, but with proper intervention, they rarely lead to death.

If a patient has been bitten by a potentially poisonous snake, call a doctor or the EMS system. If the patient must walk, have him walk slowly to prevent dispersion (spreading) of the poison through the circulation. To care for a poisonous snakebite while you await help, keep the patient calm and remove rings, watches, or tight clothing in the area. If possible, immobilize the injured part and position it below heart level. Do not apply ice or a tourniquet and do not cut or suction the wound.

Spider Bites Only two types of spiders in the United States are a serious threat to health: the black widow and the brown recluse.

- The black widow has a red hourglass mark on its abdomen. The bite causes swelling and pain at the site as well as nausea, vomiting, rigid abdomen, fever, rash, and difficulty breathing or swallowing.
- The brown recluse has a violin-shaped mark on its head. The bite causes severe swelling and tenderness and, eventually, ulceration, which enlarges around the location of the bite.

You are not expected to classify spiders and their bites accurately, so any patient bitten by a spider must be seen by a physician. To care for a patient with a spider bite, wash the area thoroughly with soap and water. Apply a cold compress to the area to reduce swelling and pain. If possible, elevate the area to slow the poison's spreading. Healing of the bite can sometimes take several months.

Burns

Burns involve tissue injury that occurs from heat, chemicals, electricity, or radiation. Be sure to teach patients about emergency treatment for burns and any follow-up care prescribed by the physician.

Types of Burns

Thermal Burns Thermal burns can be caused by contact with hot liquids, steam, flames, radiation, and excessive heat from fires or hot objects. If the burn is on the hands, face, or feet and is larger than 3 inches in diameter, call the EMS team immediately. If the burn is minor and less than 3 inches in diameter, stop the burning process by using water to cool the burn. If the victim's clothes or skin are on fire, use a wet cloth or blanket to put out the fire.

Chemical Burns Chemical burns are more likely to affect workers at chemical or industrial facilities than individuals in the home. To treat this type of burn, first remove the cause of the burn. Take care not to come in contact with the chemical. Brush off any excess dry chemical and remove any clothing contaminated with the chemical. If the Safety Data Sheet is available and it is indicated on the sheet, gently flood the area with cool water for at least 15 minutes. Cover the area with a dry, sterile dressing. If the burn is severe, call EMS to transport the patient to the hospital. Monitor the patient carefully for signs of shock.

Electrical Burns Electrical burns are injuries from exposure to electric currents, including lightning. These burns occur at the site where the electricity enters the body and where the current exits the body and enters the ground. Along the current's pathway, extensive tissue damage can occur from heat followed by chemical changes to nerve, muscle, and heart tissue. Call the EMS team immediately for these types of injuries.

Classifications of Burns The severity of a burn is determined by the following factors:

- The depth and extent of the burn area
- The source of the burn
- The age of the patient
- The body regions burned
- The patient's general health and condition

For more information about classifying and estimating the extent of burns, see the chapter *The Integumentary System*.

Choking

Choking occurs when food or a foreign object blocks a person's trachea, or windpipe. The main symptom of a choking emergency is the inability to speak. A choking person who cannot talk may give the universal sign of choking—a hand up to the throat and a fearful look. If you see someone giving the universal sign, be prepared to act promptly.

Procedure 57-3, at the end of this chapter, provides guidelines for assisting an adult or a child who is responsive and choking. The American Heart Association generally considers anyone between the ages of 1 and 8 years old a child. Procedure 57-4, at the end of this chapter, provides the guidelines for assisting an infant who is responsive and has a foreign body airway

obstruction. An infant is defined by the American Heart Association as any child younger than the age of 1 year.

Ear Trauma

Treat any cut or laceration to the ear by lightly applying a bandage, with even pressure, over the injury. It may be possible to reattach a severed ear surgically. Carefully wrap the severed ear in a sterile dressing secured with a self-adherent gauze bandage. Then wrap the ear in plastic, label it, and place it in an ice chest or over an ice pack so that it is kept chilled but is not in direct contact with the ice. Send it with the patient to the hospital.

Eye Trauma

Depending on its severity, eye trauma may require no more than an ice pack or a cold compress, or it may require hospital care. Eye trauma may result from a fall, a blow to the eye, or a wound from a pointed object. Whatever the cause, carefully examine the eye to the best of your ability and notify the physician of the patient's condition.

Eye injuries are commonly caused by foreign objects in the eye. Tiny specks cause tearing and can be painful. To remove them, use moistened sterile gauze or a tissue. Do not use a cotton ball because it may leave behind eye-irritating cotton wisps. If an object has penetrated the eye, do not try to remove it. Seek medical attention immediately.

Falls

If a patient falls and cannot get up, you will need to call for help. Do not move the patient on your own; wait until the physician or an EMT examines him. Instruct the patient not to move his head, neck, or back if injuries to those areas are suspected. When this type of injury is suspected, have someone hold the patient's neck to stabilize it until the physician or EMT arrives. Move the patient only in a life-threatening situation, such as if the building is on fire. Arrange for transport to the hospital and document the fall and injury in the patient's chart.

If the fall results in only a bump, apply ice if ordered by the healthcare practitioner and observe for bruises and swelling. Give the patient time to collect himself. Be sure to notify the doctor, who should examine the patient. Then document the fall, the injury, and the treatment in the patient's chart.

Fractures, Dislocations, Sprains, and Strains

Fractures, sprains, and other musculoskeletal injuries can result from falls and slips in the medical office. As a medical assistant, you must be able to recognize the symptoms of a fracture, dislocation, sprain, or strain and provide immediate first aid. Table 57-3 summarizes the types of fractures. Additional information about fractures and dislocations can be found in the chapter *The Skeletal System*. For more information on muscle strains and sprains, see the chapter *The Muscular System*.

Fracture and dislocation treatment depends on factors such as the nature of the injury and the patient's age and physical condition. The basic emergency steps are:

1. Keep the person calm and limit his movement.
2. Assess him for any other injuries.

TABLE 57-3 Summary of Fracture Types and Their Symptoms	
Fracture	Symptoms
Complete	The fracture extends across the bone, snapping it into two pieces.
Incomplete	The bone is cracked but not broken into two pieces.
Closed	The skin in the area of the fracture is not broken.
Open (compound)	The skin is broken by the bone fragments or the skin is broken during the course of the fracture.
Greenstick	The bone is cracked on one side and bent on the other. This is a common fracture in children.
Comminuted	The bone is broken into three or more pieces.

3. Notify the doctor or call EMS if needed.
 - Do not try to move the person until the doctor or EMS arrives.
4. If the skin is broken, cover with a sterile dressing.
5. Immobilize the extremity with a splint or sling (Figure 57-1).
 - Use rolled-up newspaper, strips of wood, or the like.
 - Immobilize the joint above and below the injury.
 - Immobilize the bone in the position it is found.
 - Do not try to put the bone back in place.
6. Place an ice pack on the affected area.
7. Monitor him for signs of shock.
8. Assess for signs of lack of circulation in the injured limb, including pale or blue skin, loss of feeling, and tingling in the area.

Immobilization is sometimes provided by the application of a splint or cast. The purpose of both splints and casts is to keep an injured body part in place and protect it as it heals. A **splint** is an appliance used for conditions that do not require rigid immobilization or, as a temporary measure, for those in which swelling is anticipated. A **cast** is a rigid, external dressing, usually made of plaster or fiberglass, that is molded to the contours of the body part to which it is applied. You may assist the physician with the application of a cast (Figure 57-2). You also may educate the patient about these basic elements of cast care:

- Report any of the following to the physician immediately: pain, swelling, discoloration of exposed portions, lack of pulsation and warmth, or the inability to move exposed parts.
- Keep the casted extremity elevated for the first day.
- Avoid indenting the cast until it is completely dry.
- Check the movement and sensation of the visible extremities frequently.
- Restrict strenuous activities for the first few days.
- Avoid allowing the affected limb to hang down for any length of time.

FIGURE 57-1 When using a splint, make sure you immobilize above and below the injured joint.

© National Safety Council/Rick Brady, photographer

- Do not put anything inside the cast.
- Keep the cast dry.
- Follow the physician's orders regarding activity restrictions.

Sprains and strains often result from sports injuries and accidents. A **sprain** is an injury characterized by partial tearing of a ligament that supports a joint, such as the ankle. A sprain also may involve injuries to tendons, muscles, and local blood vessels and contusions of the surrounding soft tissue. A **strain** is a muscle injury that results from overexertion. For example, back strain may occur when a person carries a heavy load.

Symptoms of a sprain include swelling, tenderness, pain during movement, and local discoloration. If you suspect a sprain, splint the joint, apply ice, and call the EMS system if needed. Inform the patient that an X-ray may be required to confirm there is no fracture. A strain causes pain on motion. In most cases, it should be examined by a physician, who may prescribe rest, application of heat, and a muscle relaxant.

Head Injuries

Head injuries include concussions; severe head injuries such as contusions, fractures, and intracranial bleeding; and scalp

FIGURE 57-2 Patients should be instructed to keep the cast dry and to notify the physician if they have pain or unusual sensations.

© Royalty-Free/Corbis

hematomas and lacerations. Some head injuries are life-threatening and require immediate medical attention.

Concussion A **concussion** is a jarring injury to the brain. It is the most common type of head injury. Someone who has a concussion may lose consciousness. Temporary loss of vision, pallor (paleness), listlessness, memory loss, or vomiting also can occur. Symptoms may disappear rapidly or last up to 24 hours. A concussion may produce slow intracranial bleeding. Teach the patient and the patient's family basic precautions after this type of injury. See the *Educating the Patient* feature for more information on concussions.

Severe Head Injuries **Contusions** (bruises), fractures, and intracranial bleeding cause symptoms similar to, but more profound than, the symptoms of concussions. Signs and symptoms of severe head injuries include the following:

- Leakage of clear or bloody fluid from the ears or nose
- Seizures
- Respiratory arrest

A patient with a severe head injury requires immediate hospitalization. Your priority is to monitor the patient's CABs and to begin CPR if needed.

Scalp Hematomas and Lacerations A **hematoma** is a swelling caused by blood under the skin. A scalp hematoma causes a bump on the head. This swelling can be reduced by applying ice immediately after the injury. Because blood vessels in the scalp are close to the skin, scalp lacerations often bleed profusely and look worse than they really are. Apply direct pressure to stop bleeding from a scalp laceration, wash the area with soap and water, and apply a dry, sterile dressing over the area.

Hemorrhaging

Hemorrhaging (heavy or uncontrollable bleeding) is generally the result of an injury. It also may be caused by an illness. The first-aid treatment remains the same in both cases. Bleeding can be internal or external. When administering first aid to a patient who may have internal bleeding, cover the patient with a blanket for warmth, keep the patient quiet and calm, and get medical help immediately.

Control external bleeding to prevent rapid blood loss and shock. Use direct pressure, apply additional dressings as needed, elevate the bleeding body part, and put pressure over a pressure point, as described in Procedure 57-5 at the end of this chapter. Then transport the patient to an emergency care facility.

As a last resort, if medical help is more than an hour away, you may need to use a tourniquet (Figure 57-3) to save a person's life. You apply a tourniquet over the main pressure point above the wound and tighten the tourniquet until the bleeding stops. For upper limb injuries, place the tourniquet as high as possible and tighten as much as possible. If you apply a tourniquet, make sure you write the application time on the tourniquet or the patient's forehead. New research shows that with better trauma surgery techniques, a tourniquet may be used to stop life-threatening hemorrhage without loss of the affected limb.

Multiple Injuries

Sometimes, a patient sustains more than one type of injury—for example, an arm fracture, a head injury, lacerations, and internal bleeding. Multiple injuries often result from a car accident or a fall. If you need to assist a patient with multiple injuries, assess the CABs, call EMS (or have someone else call), and perform CPR if needed. Once you have ensured that the patient has a pulse and an open airway and is breathing on his own, perform first aid for the most life-threatening injuries first.

Poisoning

A poison is a substance that produces harmful effects if it enters the body. Poisoning is serious and can result in death or permanent injury if immediate medical care is not provided.

EDUCATING THE PATIENT

Concussion

Because a concussion can cause intracranial bleeding, handle gently a patient who is being treated for this type of injury. If bleeding is slow, it might take up to 24 hours to produce symptoms. Because intracranial bleeding may require brain surgery, use the following patient education guidelines to help ensure patient safety after a concussion:

- Inform the patient that the first 24 hours after the injury are the most critical.
- Tell the patient to refrain from strenuous activity, to rest, and to return to regular activity gradually. Instruct the patient to avoid using pain medicines other than acetaminophen, unless the drugs are approved by the physician.
- Advise the patient to eat lightly, especially if nausea and vomiting occur.
- Tell a family member to check on the patient every few hours. The family member should make sure the patient knows her own name, her location, and the name of the family member.
- Instruct the family member to call for medical assistance immediately if the patient exhibits any of these warning signs:
 - Any symptom that is getting worse, such as headaches, sleepiness, or nausea, including nausea that does not go away
 - Changes in behavior, such as irritability or confusion
 - Dilated pupils (pupils that are bigger than normal) or pupils of different sizes
 - Trouble walking or speaking
 - Drainage of bloody or clear fluids from ears or nose
 - Vomiting
 - Seizures
 - Weakness or numbness in the arms or legs
 - A less serious head injury in a patient taking blood thinners or who has a bleeding disorder such as hemophilia

In addition to being able to handle a poisoning emergency, you need to educate patients in how to do the same. Teach them about the symptoms of and treatment for the different types of poisoning and provide them with pamphlets that

describe the procedures to follow and stickers with the telephone number of the regional poison control center.

The majority of accidental poisonings happen to children younger than the age of 5. Young children are not necessarily put off by strong smells or burning sensations when they swallow something. Common causes of poisoning in children are household cleaning products, household plants, and medications. Poisons also can be caused by improperly prepared or contaminated food. These types of poisons are ingested or swallowed.

Poisoning that results from coming in contact with plants (called absorbed poisoning), such as poison ivy, poison sumac, and poison oak, is common and generally fairly minor. It can be serious, however, if the poisoning occurs over a large body surface.

Poisons also can be inhaled. This situation occurs when a person inhales a poisonous gas such as carbon monoxide or the fumes from burning poisonous plants.

Ingested Poisons Symptoms of ingested poisoning include abdominal pain and cramping; nausea; vomiting; diarrhea; odor, stains, or burns around or in the mouth; drowsiness; and unconsciousness. You also should suspect poisoning if packages containing poisonous substances are near a person who has one or more of these symptoms. Swallowed poison remains in the stomach only a short time. Most of it is absorbed while in the small intestine.

It is crucial to call a poison control center (1-800-222-1222), hospital emergency room, doctor, or the EMS system for instructions if you think a patient has swallowed a poison. When you call, you will need to know

FIGURE 57-3 Apply a tourniquet as a last resort—if the bleeding cannot be stopped and medical help is more than an hour away. Record the time applied on the tourniquet or the patient's forehead.

- The patient's age.
- The name of the poison.
- The amount of poison swallowed.
- When the poison was swallowed.
- Whether or not the person has vomited.
- How much time it will take to get the patient to a medical facility.

Poisons vary in their toxicity. Some cause damage right away; others cause damage several hours later. If the patient is alert and not having convulsions, follow these steps:

1. Call the regional poison control center.
2. Seek immediate medical attention.
3. Monitor the patient's vital signs.
4. Watch for increasing nausea and vomiting.

Do not induce vomiting unless directed by a medical authority. The patient may have ingested a strong acid, alkali, or petroleum product, such as chlorine bleach or gasoline. These products may cause further damage to the throat and esophagus during vomiting. If you do not know what the patient ingested, never induce vomiting.

Turn the patient on her left side. This position delays stomach emptying by several hours and prevents aspiration if the patient vomits. Take both the poison container and vomited material to the hospital for inspection.

Food poisoning, another type of ingested poisoning, can occur when bacteria produce toxins in food. Botulism, for example, results from eating improperly canned or preserved foods contaminated with the bacterium *Clostridium botulinum*. Symptoms appear within 12 to 36 hours after eating contaminated food. Initial symptoms include dry mouth, sore throat, weakness, vomiting, and diarrhea.

Food poisoning is often difficult to detect because the signs and symptoms vary greatly. A patient with food poisoning usually has abdominal pain, nausea, vomiting, gas, frequent bowel sounds, and diarrhea. Chills, joint pain, and excessive sweating also may occur. If you suspect that a patient has food poisoning, call the poison control center and arrange for immediate transport to the hospital.

Absorbed Poisons Most people have had the red, itchy rash that results from contact with poison ivy, poison sumac, or poison oak. In some people, however, the rash may be accompanied by a generalized swelling, burning eyes, headache, fever, and abnormal pulse or respirations.

To treat a patient who has come in contact with an absorbed poison, call the regional poison control center. Have the patient immediately remove all contaminated clothing. Then wash the affected skin thoroughly with soap and water, drench it with alcohol, and rinse well. To help relieve symptoms, apply wet compresses soaked with calamine lotion. Also, suggest baths in colloidal oatmeal or applications of a paste made from 3 teaspoons baking soda and 1 teaspoon water to soothe the itching. If the rash is severe, the doctor may prescribe a corticosteroid ointment. Tell the patient to seek medical assistance if a fever or swelling develops.

Inhaled Poisons A patient may inhale poisons by breathing air contaminated by chemicals in the workplace or by a malfunctioning stove or furnace in the home. The patient may not realize she has been exposed to a poisonous gas until symptoms arise. Even then, she may merely suspect the flu because some symptoms of inhalation poisoning mimic those of influenza. Common symptoms include headache, tinnitus (ringing in the ears), angina (chest pain), shortness of breath, muscle weakness, nausea, vomiting, confusion, and dizziness, followed by blurred or double vision, difficulty breathing, unconsciousness, and cardiac arrest. Also, a patient who has facial burns may have sustained an inhalation injury.

To treat poisoning by inhalation, first get the patient into fresh air. Have someone call the EMS system or the regional poison control center. Loosen tight-fitting clothing and wrap the patient in a blanket to prevent shock. Check the patient's CABs and begin CPR if needed.

Carbon monoxide is a major cause of inhalation poisoning in the home. It is a colorless and odorless natural gas produced by incomplete combustion of organic fuels, such as coal, wood, or gasoline. Carbon monoxide is especially dangerous in closed spaces because, when inhaled, it replaces oxygen in the blood. If you suspect carbon monoxide poisoning, look for clues in the environment such as a malfunctioning furnace or a car engine left running in a closed space such as a garage.

Mild carbon monoxide poisoning can cause headache and flu-like symptoms without fever. Moderate poisoning may cause tinnitus, drowsiness, severe seizures, coma, and cardiopulmonary problems. Because the gas is odorless, people are often unaware they are being poisoned. They may fall asleep, lapse into unconsciousness, and die.

Weather-Related Injuries

Exposure to extreme cold, extreme heat, and the sun's damaging rays can cause weather-related injuries, which may require emergency medical attention.

Hypothermia Hypothermia, caused by exposure to cold, occurs when a person loses more body heat than he can produce, resulting in a body temperature below 95°F. This condition usually occurs in the very old or very young, or in chronically ill or malnourished individuals. People who are outdoors with insufficient clothing in the winter or who get wet in cold weather are more likely to suffer from hypothermia.

Hypothermia symptoms include lethargy, loss of coordination, confusion, and uncontrollable shivering. If the person's body temperature is extremely low, he may stop shivering. If untreated, hypothermia can result in cardiac arrest and coma.

Treat hypothermia by moving the person inside if possible and covering him with blankets. If he is wet, remove his wet clothing. If he is confused or unconscious, monitor his breathing and call the EMS system. If he is awake and alert, give him warm, nonalcoholic liquids.

Frostbite When body tissues are exposed to below-freezing temperatures, frostbite can occur. Frostbite causes ice crystals to form between tissue cells, and these crystals enlarge as they

extract water from the cells. Frostbite also causes obstruction to the blood supply in the form of blood clots. This aspect of frostbite prevents blood from flowing to the tissues and causes additional, severe damage to cells.

Frostbite symptoms include white, waxy, or grayish yellow skin. The affected body part feels cold, tingling, and painful. The skin surface may feel crusty and the underlying tissue soft in comparison. If the frostbite is deep, the body part may feel cold and hard and not be sensitive to pain. Blisters may appear after rewarming.

Treat frostbite by wrapping warm clothing or blankets around the affected body part or placing it in contact with a warm body part. Do not rub or massage the affected area, or you may cause further damage to the frozen tissue. Call for medical assistance. If you are in a remote area, use the wet rapid rewarming method. This method involves placing the affected part in warm (100°F to 104°F) water. Hot water should be added at regular intervals to keep the temperature of the bath stable. As an alternative method, you can heat the affected area with warm compresses. Continue rewarming for 20 to 40 minutes. After the affected area becomes soft, place dry, sterile gauze between skin surfaces, such as between the toes or the fingers or between the ear and the side of the head. Do not massage the skin or break blisters.

Heatstroke Heatstroke is an overheating of the body, which results from prolonged exposure to high temperatures and humidity. This condition may lead to excessive loss of fluids (dehydration) and insufficient blood in the circulatory system (hypovolemic shock). High body temperature (over 104°F) can damage tissues and organs throughout the body. If untreated, the patient will die. People most susceptible to heatstroke are those who have previously had heatstroke, children, the elderly, athletes, and patients who are obese or have circulatory problems or other chronic illnesses.

Symptoms of heatstroke include the following:

- Hot, dry skin (lack of sweating)
- High body temperature
- Altered mental state
- Rapid pulse
- Rapid breathing
- Dizziness
- Headache
- Nausea and vomiting
- Weakness

If you suspect that a patient has heatstroke, check the patient's CABs and call the EMS system. Move the patient to a cool place and remove outer clothing unless it is made of light cotton or other light fabric. Also, cool the patient with any means available, such as gentle spraying with a hose. Move the patient to an air-conditioned place if available, fan vigorously, or apply a wet sheet. If the humidity is above 75%, place ice packs on the patient's groin and armpits. Stop cooling when the patient's mental state improves. Keep the patient's head and shoulders slightly elevated.

Sunburn Do not dismiss a sunburn as trivial. It is a burn that can cause redness, tenderness, pain, swelling, blisters, and peeling skin and may lead to skin damage or cancer later in life.

Soak sunburned skin in cool water to help reduce the heat. Apply cold compresses, and later calamine lotion, to relieve the burning sensation. Have the patient elevate the legs and arms to prevent swelling. The patient also should drink plenty of water and take a pain reliever.

Educate the patient about the importance of using sunscreen and reapplying it every 2 to 3 hours when outdoors. Advise the patient to stay out of direct sunlight between 10:00 a.m. and 2:00 p.m. because the sun's rays are strongest during that period.

Wounds

A wound is an injury in which the skin or tissues under the skin are damaged. Wounds can be either open or closed. Figure 57-4 shows the various types of wounds.

Open Wounds An open wound is a break in the skin or mucous membrane. Types of open wounds include incisions, lacerations, amputations, abrasions, and punctures.

Incisions and Lacerations An incision is a clean and smooth cut, like that from a kitchen knife. A laceration has jagged edges, as may result when a child steps on a piece of broken glass in the sand at the beach. Care of minor incisions and lacerations involves controlling bleeding by covering the wound with a clean or sterile dressing and applying direct pressure. After the bleeding stops, clean and dress the wound. Procedure 57-6, at the end of this chapter, explains how to clean minor wounds. Teach the patient the importance of keeping the wound clean and checking for signs of infection, such as heat, redness, pain, and swelling.

If the wound is deep and involves muscle, tendons, the face, the genitals, the mouth, or the tongue, control the bleeding with direct pressure to the wound (with a sterile dressing or clean cloth held against its surface), elevation, and use of pressure points. Contact the doctor and, if necessary, the EMS system.

Amputations If a fingertip or toe is completely or nearly severed, quick action may increase the likelihood that it can be saved. Elevate the injured extremity, cover the digit with a dry dressing, and immobilize the hand or foot. Retrieve the severed digit, wrap it in gauze, put it in a plastic bag, put the bag on ice (making sure the digit does not come in direct contact with the ice), and send the part with the patient to the hospital.

Abrasions An abrasion is a scraping of the skin, as when someone slides across rough dirt during a softball game. Abrasions require washing with soap and water. Be sure to remove all the dirt and debris to prevent tattooing (dark discoloration under the skin). Minor abrasions do not need a dressing or bandage, but large ones do. Various types of bandaging are shown in Figure 57-5. As with any wound, teach the patient to watch for signs of infection.

FIGURE 57-4 Different types of wounds produce different degrees of tissue damage.

Punctures A puncture wound is a small hole created by a piercing object, such as a bullet, a knife, a nail, or an animal tooth. Rinse the wound under running water for 15 minutes. Then clean the wound with soap and water and apply a dry, sterile dressing. Puncture wounds are a potential breeding ground for tetanus bacteria because the bacteria can live and thrive in the absence of oxygen. If the patient has not had a tetanus toxoid immunization in the past 7 to 10 years, inform the physician so that one can be ordered.

Closed Wounds A closed wound is an injury that occurs inside the body without breaking the skin. Closed wounds, often called contusions, are caused by a blunt object striking the tissue. This action produces broken blood vessels and internal, localized bleeding (hematoma) below the area that has been struck. Treat such a wound with cold compresses to reduce swelling. The affected area will turn from black and blue to green to yellow as blood pigments oxidize. Inform the patient that these color changes are part of the normal healing process.

the importance of following the physician's orders for follow-up care is also your responsibility. Common disorders include the following:

- Abdominal pain
- Asthma
- Dehydration
- Diarrhea
- Fainting
- Fever
- Hyperventilation
- Nosebleed
- Tachycardia
- Vomiting

Abdominal Pain

Sudden, acute abdominal pain accompanied by fever may indicate an emergency that requires surgery. The patient may complain of spasmodic contractions and knife-like or dull pain. Ask the patient if the pain is localized or radiating. The pain's location gives clues to its cause. Right upper quadrant pain, for example, may signal a gallbladder attack. Right lower quadrant pain may indicate appendicitis. The following are other causes of abdominal pain:

- Internal hemorrhage
- Intestinal perforation
- Intestinal obstruction
- Peptic ulcer
- Hernia

Common Disorders

LO 57.4

A variety of common disorders frequently require emergency medical intervention. As a patient educator, you can help ensure that patients recognize the symptoms of illnesses and know when to call for medical assistance. Teaching patients

FIGURE 57-5 Apply a bandage, as needed, to a wound or an injury.

- Abdominal aortic aneurysm
- Ectopic pregnancy
- Kidney stones
- Trauma to the area (wounds or blows)

While waiting for patient transport, have the patient lie on his back with his knees flexed (unless there is a wound or swelling in the abdomen). This position lets the abdominal muscles relax. Keep the patient quiet and warm, and stay calm and attentive. Do not give anything by mouth, and keep

an emesis (vomiting) basin handy in case the patient vomits. Do not apply heat to the abdomen, as heat may exacerbate inflammation. Monitor the patient's pulse and consciousness and check for signs of shock.

Asthma

Asthma is a common disorder caused by spasmodic narrowing of the bronchi. It is often an inherited tendency, and several members of one family may suffer from it. A patient who is having an acute attack wheezes, coughs, and is short

of breath. She may become frightened and feel as if she cannot get enough air. If you suspect an asthma attack, check the patient's CABs and notify the doctor at once. You may assist the patient in using a respiratory inhaler if she carries one with her. If directed, administer a mini-nebulizer treatment with a bronchodilator (drug that opens the bronchi), such as albuterol or epinephrine.

Dehydration

Dehydration results from a lack of adequate water in the body. The body's fluid intake is not sufficient to meet its fluid needs. Severe dehydration can result from vomiting, excessive heat and sweating, diarrhea, or lack of food or fluid intake. The following are symptoms of dehydration:

- Extreme thirst
- Tiredness
- Light-headedness
- Abdominal or muscle cramping
- Confusion (especially in elderly people)

Perform the following steps to administer first aid to a dehydrated person:

1. Move the victim into the shade or to a cool area.
2. To replace lost fluids, give the victim frequent, small amounts of decaffeinated fluids.
3. If symptoms persist or are accompanied by nausea, diarrhea, or convulsions, call for the EMS system or a physician.

Diarrhea (Acute)

Acute diarrhea can be caused by an intestinal infection, food poisoning, a bowel disorder, or medication side effects. Severe diarrhea causes dehydration and dangerous electrolyte imbalances that can lead to shock. Symptoms of shock include rapid pulse, low blood pressure, and pale, clammy skin.

Help the patient lie on his back and elevate his legs. Report the patient's condition to the doctor. As directed, prepare to assist in administering intravenous fluids to correct dehydration and restore electrolytes, as well as to draw blood for testing.

Fainting (Syncope)

Fainting, or syncope, is a partial or complete loss of consciousness, which usually follows a decrease in blood flow to the brain. Before fainting, patients may feel weak, dizzy, cold, or nauseated. They may perspire or look pale and anxious.

If you are with a patient who feels as if she is going to faint, tell her to lower her head between her legs and to breathe deeply. Stay with her until the feeling passes. If the patient is having difficulty breathing or faints, lay her flat on her back with her feet slightly elevated. Loosen tight clothing and apply a cold cloth to her face. Observe the patient carefully, monitoring her breathing and level of consciousness. Observe for weakness in her arms and legs. Let her rest for at least 10 minutes after she regains full consciousness. Notify the physician that the patient fainted.

If your efforts do not revive a patient who has fainted, instead call the physician and the EMS system, as the patient may be slipping into a coma.

Fever

Fever is a common clinical sign that often indicates infection. Mild or moderate fever can accompany a cold or an upset stomach. It can usually be managed with aspirin (in adults only), ibuprofen, or acetaminophen. A fever of 106°F or higher (hyperthermia) is dangerous, however, because irreversible brain damage can occur if the fever is not lowered immediately.

If a patient's temperature is dangerously high, you must proceed at once to check the other vital signs and the level of consciousness. Notify the doctor and be prepared to start rapid cooling measures if directed to do so. Place ice packs on the groin and axilla, or give the patient a tepid sponge bath. If the patient is a child, be prepared to manage seizures (discussed later in this chapter). Do not give aspirin to a child with a fever unless directed by a physician.

Hyperventilation

Some patients who are under a great deal of stress lack the skills to deal with the stress effectively. They may seem anxious, frazzled, and more emotional than average patients. Patients under stress may begin to hyperventilate, or breathe too rapidly and too deeply. This breathing disturbs the normal balance of oxygen and carbon dioxide in the blood, and the carbon dioxide concentration falls below normal levels. Patients who are hyperventilating also may feel light-headed and as if they cannot get enough air. In addition, they may have chest pain and feel apprehensive.

Move a hyperventilating patient to a quiet area. Have the patient sit peacefully and visualize a calm and serene environment, such as a beach or the mountains. With a calm and soothing voice, coach the patient to take slow, normal breaths. If the patient continues to hyperventilate after several minutes of coaching, notify the physician, as this may indicate a more serious lung problem.

Nosebleed

Nosebleed, or **epistaxis**, can occur for a variety of reasons: blowing the nose too hard, local irritation or dryness, frequent sneezing, fragile or superficial blood vessels, high blood pressure, a blow to the nose, and a foreign body in the nose. Nosebleeds are common in children, especially at night.

Treat a nosebleed by having the patient sit up with the head tilted forward to prevent blood from running down the back of the throat. Next, have the patient gently pinch the nostrils shut at the bottom for at least 5 minutes. If that does not stop the bleeding, continue to pinch the nostrils for an additional 5 minutes. If the bleeding cannot be controlled within 10 minutes, alert the physician.

Tachycardia

Tachycardia is a rapid heart rate, generally in excess of 100 beats per minute. A patient with tachycardia may report having **palpitations**, unusually rapid, strong, or irregular pulsations

of the heart. He may feel as if his heart is pounding. Help the patient lie down, take his vital signs, and, if instructed, obtain an electrocardiogram (ECG). (Electrocardiography is discussed in the *Electrocardiography and Pulmonary Function Testing* chapter.) If tachycardia is accompanied by low blood pressure and light-headedness, notify the physician immediately. These symptoms indicate the patient could faint or go into shock. Remain with the patient and keep him calm.

Vomiting

Vomiting is a symptom common to many disorders, ranging from food poisoning to various infections. When severe, it can lead to dehydration and dangerous changes in electrolyte levels, especially in patients who are very young, very old, or diabetic or who also have diarrhea. Because these problems can be severe, notify the doctor and provide appropriate care. Procedure 57-7, at the end of this chapter, describes how to provide emergency care for a patient who is vomiting.

► Less Common Disorders

LO 57.5

Even though some disorders are less common than those previously discussed, you should still be familiar enough with them to handle them effectively if a physician or an EMT is not immediately available. Educate patients about symptoms they may encounter that require emergency medical intervention and about the importance of follow-up care when recovering from such illnesses or disorders. Less common disorders that may require emergency medical intervention include the following:

- Anaphylaxis
- Bacterial meningitis
- Diabetic emergencies
- Gallbladder attack
- Heart attack (myocardial infarction)
- **Hematemesis** (the vomiting of blood)
- Obstetric emergencies
- Respiratory arrest
- Seizures
- Shock
- Stroke
- Toxic shock syndrome
- Viral encephalitis

Anaphylaxis

Anaphylaxis, or anaphylactic shock, is a severe, often life-threatening allergic reaction. The reaction can be immediate or delayed up to 2 hours or more. It happens to people who have become sensitized to certain substances. For example, it

can result from eating certain foods, being stung by an insect, or taking a particular type of medication, such as penicillin.

Initial signs of anaphylaxis include itchy, red, hot skin. Swelling occurs in the face, mouth, and throat. The patient may have trouble breathing and swallowing and feels as if he has a “lump in the throat.” Other symptoms include pallor, perspiration, abdominal pain or nausea, and a weak, rapid, irregular pulse. If you detect these symptoms or if the patient becomes restless, has a headache, or says his throat feels as if it is closing up, take the following steps immediately.

Check the patient’s CABs and then notify the healthcare practitioner. As directed, administer epinephrine, oral antihistamines, and oxygen and help the patient into semi-Fowler’s position. After the patient receives epinephrine, monitor his vital signs every 2 to 3 minutes. Note skin color and monitor the airway. If he does not recover quickly, arrange for immediate transport to the hospital.

When severely allergic patients stabilize, the practitioner prescribes an epinephrine autoinjector for patients to carry with them. You are responsible for teaching patients how to use this device. See the *Assisting in Other Medical Specialties* chapter for more information about using an autoinjector.

Because of the possibility of anaphylaxis, a patient who has just received any type of injection should routinely be kept in the office for 20 to 30 minutes of observation. This procedure reduces the possibility that an allergic reaction to the medication will occur while the patient is unattended.

Bacterial Meningitis

Bacterial meningitis is almost always a complication of another bacterial infection, such as otitis media (middle ear infection) or pneumonia. So first find out whether the patient currently has or recently has had a bacterial infection. The signs of bacterial meningitis are fever, chills, headache, neck stiffness, and vomiting. If the patient has these signs and then develops a fever of 102°F, becomes less alert, has altered respirations, or experiences seizures, the infection has progressed to a dangerous state.

If these signs are present, assess the patient’s CABs and notify the physician of the change in the patient’s condition. Expect to arrange for transport to the hospital, where the patient will be treated with intravenous antibiotics.

Diabetic Emergencies

Patients who have diabetes or prediabetes must maintain healthy blood glucose levels. It is important that they know the signs of both low and high blood sugar. Symptoms of **hypoglycemia** (low blood sugar) include the following:

- Dizziness
- Headache
- Confusion
- Hunger
- Weakness
- Shaking/trembling
- Full, rapid pulse
- Pallor

Symptoms of **hyperglycemia** (high blood sugar) include the following:

- Dry mouth
- Intense thirst
- Frequent urination
- Muscle weakness
- Blurred vision

You also should be familiar with the signs and symptoms of the two most common diabetic emergencies you will encounter: insulin shock and diabetic coma.

Insulin Shock Insulin shock is basically very severe hypoglycemia, in which a patient has too little sugar in the blood. Insulin shock occurs when insulin levels are so high that they move too much sugar from the blood into cells. Symptoms include rapid pulse; shallow respiration; hunger; profuse sweating; pale, cool, clammy skin; double vision; tremors; restlessness; confusion; numbness and tingling in the hands and feet; and possibly fainting. Insulin shock can usually be corrected with administration of some form of sugar (candy, juice, or regular soda for a conscious patient). If the cause of a diabetic emergency is unknown, give sugar if the patient is conscious. Patients will improve quickly if the cause is insulin shock and will not be harmed if the cause is diabetic coma, provided they are then transported to the hospital.

Diabetic Coma Diabetic coma is the end result of severe hyperglycemia. It occurs when insulin levels are insufficient to move blood sugar into body cells. Its symptoms include rapid, deep, gulping breaths; flushed, warm, dry skin; thirst; acetone breath (a sweet or fruity odor from the mouth); drowsiness, disorientation, or confusion; and gradual loss of consciousness. If you suspect diabetic coma, notify the doctor at once and expect to arrange transport to the hospital.

Gallbladder Attack (Acute)

A classic acute gallbladder attack occurs after a person eats a high-fat meal rich in cholesterol. The patient may wake up in the night with acute abdominal pain (gallbladder colic) in the right upper quadrant. The pain is caused by inflammation of the gallbladder, usually related to gallstones obstructing the cystic duct. This duct carries bile from the gallbladder to the hepatic duct, delivering bile to the duodenum. The pain may radiate to the back between the shoulder blades or be localized in the epigastric region (the upper central region of the abdomen) and the front chest area. The attack may be accompanied by nausea and vomiting. The pain is usually so severe that the patient seeks medical attention; many patients think they are having a heart attack.

Gallbladder attacks caused by gallstones are more common among women who are older than age 40 and obese, and the frequency of attacks increases with age (especially after age 65). Diagnosis is usually made with the help of ultrasonography. The patient may require surgery to remove the gallbladder.

Heart Attack

A heart attack, or myocardial infarction (MI), occurs when the blood flow to the heart is reduced as a result of blockage in the coronary arteries or their branches. Chest pain is the cardinal symptom of a myocardial infarction. The patient may describe the pain as crushing, burning, heavy, aching, or like that of indigestion. The pain may radiate down the left arm or into the jaw, throat, or both shoulders. It may be accompanied by shortness of breath, sweating, nausea, and vomiting. The patient may be pale and have a feeling of doom. If you cannot easily detect pallor (paleness) because the patient has dark skin, check the patient's inner lip for paleness. Elderly patients may experience atypical symptoms of a myocardial infarction, such as jaw pain, because responses to pain diminish during the aging process. The pain of a myocardial infarction is not relieved by nitroglycerin.

If you think a patient is having a myocardial infarction, follow the American Heart Association's "Chain of Survival," outlined here:

- Immediate recognition and activation of EMS
- Early CPR
- Rapid defibrillation
- Advanced life support
- Post-cardiac arrest care

Do not let the patient walk. Loosen tight clothing and have the patient sit up to aid breathing. The physician may order you to administer oxygen at 4 to 6 liters per minute; make sure no one in the area is smoking. Stay with the patient, observe the CABs, and begin CPR if required. If directed, obtain an ECG. Take apical and radial pulses, as instructed by the physician. Be prepared to obtain medication from the crash cart or use a defibrillator if required. The American Heart Association guidelines for CPR key components are found in Table 57-4.

Ventricular fibrillation (VF)—the most common cause of cardiac arrest—is an abnormal heart rhythm. During VF, the heart's rhythm becomes chaotic and the heart does not pump blood. VF treatment is defibrillation using a medical device called a defibrillator, which works by delivering an electric shock to the heart to interrupt the chaotic rhythm. Defibrillators are effective only if used within minutes of the patient's collapse. An **automated external defibrillator (AED)** is a computerized defibrillator programmed to recognize VF and other lethal heart rhythms (Figure 57-6). These devices are found in many public places, including airports, but also may be used at the clinic where you are employed.

To use an AED, attach the adhesive electrode pads to the client's chest in a specific arrangement as determined by the manufacturer. Look at the illustration on the electrode's packing or machine. Activate the AED and it will analyze the heart's rhythm and determine if a shock is required. Pressing the "Shock" button will deliver an electrical charge to the patient's heart by way of the AED's electrode wires attached to the chest.

In order to use an AED, you must be properly trained. Training is included as part of the CPR courses of the American Red Cross and the American Heart Association.

FIGURE 57-6 An automated external defibrillator delivers an electric current to the heart to stop a chaotic rhythm such as ventricular fibrillation.

© McGraw-Hill Education

Obtaining CPR and first-aid certification will be an asset to you as a medical assistant and is necessary to receive medical assisting certification by some agencies.

Hematemesis

Hematemesis is the vomiting of blood. A patient who vomits bright red blood may have a gastrointestinal disorder, such as a bleeding ulcer. A patient who vomits blood that looks like coffee grounds may have slow bleeding into the stomach.

Quickly check the vital signs of a patient with hematemesis. If pulse and breathing are rapid and blood pressure is low, the patient may be going into shock. Notify the doctor immediately and get the crash cart to help the doctor start an intravenous line to replace lost fluid. Then call the EMS system.

Obstetric Emergencies

If you work in an obstetric practice, you may see emergencies unique to this specialty. Although the physician handles most obstetric emergencies, you can assist by asking the patient

specific questions about her problem so that the physician can decide what treatment is necessary.

Set up written protocols to handle these situations. For example, if the patient calls from home and reports gushing vaginal bleeding, your protocol may be to call the EMS system for her and tell her to lie down with her feet elevated. If the patient has a miscarriage, have her bring the expelled tissue with her to the office or hospital. (See the *Assisting in Reproductive and Urinary Specialties* chapter for more information.)

Respiratory Arrest

Respiratory arrest, or lack of breathing, is usually preceded by respiratory distress symptoms, which include difficulty breathing, rapid breathing, palpitations, racing pulse, high or low blood pressure, sweating, pale or bluish skin, and decreasing level of consciousness. If a patient shows these symptoms, notify the doctor right away. If the patient develops respiratory arrest, have someone call the doctor and the EMS system while you perform CPR.

Seizures

A seizure, or convulsion, is a series of violent and involuntary muscle contractions caused by abnormal electrical activity in the brain. Seizures are usually related to brain malfunctions that can result from diseased or injured brain tissues. A seizure may be caused by high fever, epilepsy (a brain disorder that causes seizures with varying severity), meningitis, diabetic states, and many other medical problems.

Follow this emergency care for seizure patients:

1. Remove objects that may cause injury.
2. Place the patient on the floor or the ground. If possible, position him on his side with his head turned to the side to help keep the airway open and unobstructed by the tongue. This position is especially important if the patient vomits, to prevent aspiration of vomitus into the lungs.
3. Loosen restrictive clothing and never place anything in the patient's mouth.
4. Protect the patient from injury, but do not try to hold him still during convulsions.
5. After convulsions end, keep the patient at rest, positioned for drainage from the mouth.
6. Make sure the patient is breathing. If he is not, begin rescue breathing or CPR.
7. Take vital signs and monitor respirations closely.
8. Move the patient to an exam room or have him taken to a medical facility.

Shock

Generally speaking, shock is a life-threatening state associated with cardiovascular system failure. It can bring to a stop all normal metabolic functions. This condition prevents the vital organs from receiving blood.

Early symptoms of shock include restlessness; irritability; fear; rapid pulse; pale, cool skin; and increased respiratory rate. Treat a patient in shock by elevating the feet

TABLE 57-4 Key Components of Basic Life Support

Recommendations			
Component	Adults	Children	Infants
Recognition	Unresponsive, all ages		
	No breathing or abnormal breathing like gasping		
	No pulse palpated within 10 seconds (healthcare professionals)		
CPR sequence	CAB	CAB	CAB
Compression rate	At least 100/min		
Compression depth	At least 2 inches	2 inches or ⅓ anteroposterior chest circumference	1½ inches or ⅓ anteroposterior chest circumference
Chest wall recoil	Complete recoil between compressions		
Compression interruptions	Limit chest compression interruptions to less than 10 seconds if at all		
Airway	Head tilt—chin lift		
	Healthcare professionals only—jaw thrust if indicated by trauma		
Compression to ventilation ratio	30:2 (1 or 2 rescuers)	30:2 (single rescuer) 15:2 (2 healthcare professional rescuers)	30:2 (single rescuer) 15:2 (2 healthcare professional rescuers)
Ventilations for untrained rescuer	Compressions only		
Defibrillation	Use AED as soon as possible. Minimize interruptions in chest compressions before and after shock. Resume compressions immediately after each shock.		

Adapted from 2010 American Heart Association Guidelines for Cardiopulmonary Resuscitation and Emergency Cardiovascular Care Service, Pt. 4, tab. 1.

8 to 12 inches. If you suspect a head injury, however, keep the patient flat. Monitor the patient's CABs and take steps to control bleeding. Keep the patient warm and loosen any tight clothing. Notify the physician and call the EMS system.

Several types of shock are possible. Anaphylactic shock, or anaphylaxis, is usually associated with an allergic reaction, as previously discussed. Hypovolemic shock and septic shock are two other types of shock.

Hypovolemic Shock Hypovolemic shock results from insufficient blood volume in the circulatory system. It occurs after an injury that causes major fluid loss, such as hemorrhage or burns. Patients with hypovolemic shock must be transported to an emergency facility immediately.

Septic Shock Septic shock results from massive, widespread infection that affects the ability of the blood vessels to circulate blood. Common causes are urinary tract infection (UTI) (especially in older adults), postpartum infection, and a variety of infections in patients with immunosuppression (as caused by chemotherapy or acquired immunodeficiency syndrome [AIDS]).

Stroke

A stroke, or **cerebrovascular accident (CVA)**, occurs when the blood supply to the brain is impaired. This impairment

may cause temporary or permanent damage, depending on how long the brain cells are deprived of oxygen.

A minor stroke can cause headache, confusion, dizziness, tinnitus, minor speech difficulties, personality changes, weakness of the limbs, and memory loss. A major stroke typically produces loss of consciousness, paralysis on one side of the body, difficulty swallowing, loss of bladder and bowel control, slurred or garbled speech, and unequal pupil size. The American Stroke Association recommends using the acronym FAST to assess if someone is having a stroke.

- **F**—facial drooping; ask the patient to smile, do both sides of the mouth raise?
- **A**—arm weakness; have the patient raise both arms, do both arms stay up?
- **S**—speech difficulty; have the patient repeat a simple sentence, is it correct?
- **T**—time to call 911; don't delay, even if the patient seems to be getting better.

If a patient has a stroke in the office, notify the physician at once and call the EMS system. Maintain the patient's airway by turning the head toward the affected side to allow secretions to drain out rather than be aspirated. Loosen tight clothing. If directed by the physician, monitor vital signs and administer oxygen.

Toxic Shock Syndrome

Toxic shock syndrome (TSS) is an acute infection most often caused by the bacterium *Staphylococcus aureus*. The toxin produced by bacterial overgrowth can act as a poison, causing severe, life-threatening symptoms. Although the infection is most common in menstruating women who are using tampons at the time of onset, the link between tampon use and TSS is unclear.

TSS symptoms include high fever, intense muscle aches, vomiting, diarrhea, headache, bouts of violent shivering, vaginal discharge, red eyes, and a decreased level of consciousness. A sign specific to TSS is a deep red rash on the palms of the hands and the soles of the feet. This skin then sloughs off. A menstruating patient with these symptoms should be instructed to remove the tampon immediately and replace it with a sanitary napkin.

TSS is treated with intravenous antibiotics and fluids. The patient will require hospitalization.

Viral Encephalitis

Viral encephalitis is a severe brain inflammation caused directly by a virus or secondary to a complication resulting from a viral infection. Viral encephalitis may result from an epidemic or may arise sporadically. This condition requires accurate identification and prompt treatment. Symptoms develop suddenly, beginning with fever, headache, and vomiting. They quickly progress to stiff neck and back, decreased level of consciousness (from drowsiness to coma), and paralysis and seizures.

The level of consciousness must be monitored frequently in a patient with viral encephalitis. Prepare the patient for treatment with antiviral drugs and arrange for transport to a hospital for a lumbar puncture and other diagnostic tests.

► Common Psychosocial Emergencies

LO 57.6

You will probably encounter psychosocial emergencies in the medical office at some point. These may result from drug or alcohol abuse, spousal abuse, child abuse, or elder abuse. Handle these situations as directed in the *Patient Interview and History* chapter. If you encounter patients who have overdosed on drugs, exhibit violent behavior, mention suicide, or have been raped, follow the specific clinical responsibilities described in this section.

You also may be responsible for referring patients with psychosocial emergencies to resources in the community. Some of these resources are listed in Table 57-5.

A patient who is overdosing on drugs can suffer serious medical problems and can even die. If a patient who has taken an overdose is brought to the medical office, call the EMS system immediately and arrange for transport to the hospital.

Patients on drugs may become violent during withdrawal from the substance or while under the influence. If, at any time, a patient becomes aggressive or threatening, follow office protocol for handling violent behavior. The protocol should state when to call the police, how to document the incident, and when to notify the insurance carrier.

TABLE 57-5 Resources for Patient Assistance

Resource
Al-Anon Family Groups
Alcoholics Anonymous
Mothers Against Drunk Driving (MADD)
Narcotics Anonymous
National Child Abuse Hotline
National Coalition Against Domestic Violence
National Council on Child Abuse and Family Violence
National Domestic Violence Hotline
National Institute for Alcohol Abuse and Alcoholism (NIAAA)
National Institute on Drug Abuse
National Organization for Victim Assistance
Students Against Destructive Decisions

During a psychosocial emergency, a patient may tell you he is so depressed that he has thought about killing himself. Allow the patient to talk freely. Listen carefully without interrupting. Whenever a patient mentions suicide or talks about life in ways that make you suspect suicidal tendencies, discuss your suspicions with the physician. Take comments on suicide seriously, no matter how casual they may seem.

Victims of rape may be of any age and either gender, but more than 90% are women. If a patient says she has been raped, provide privacy. Limit the number of people who ask her questions. She may feel traumatized, embarrassed, and fearful. Do not make her go through the office routine at this time.

If the physician asks you to speak to the patient, explain to her that you are legally required to contact the police so that they can file a report. The patient can decide later whether she wishes to press charges.

Contact the local rape hotline and request that a rape counselor come to the office to stay with the patient during the exam and police report procedures. The physician should be familiar with state laws for collecting specimens and the protocol for caring for a rape victim.

The procedure of ensuring that a specimen is obtained from the victim and is correctly identified, that the specimen is under the uninterrupted control of authorized personnel, and that the specimen has not been altered or replaced is called *establishing chain of custody*. This procedure is required for medicolegal issues such as evidence of rape and for tests for illicit drug use. If the chain between the victim and the specimen cannot be proved to have remained unbroken, the specimen must be considered invalid. The steps for establishing a chain of custody are outlined in the *Collecting, Processing, and Testing Urine and Stool Specimens* chapter and are essentially the same for any specimen with a medicolegal purpose. These general steps help maintain an intact chain of custody. Always refer to your office's procedures to make sure you are meeting all relevant requirements.

► The Patient Under Stress

LO 57.7

In emergency situations, patients and family members are under a great deal of stress. You must realize that people react differently to emergency situations. You can learn how to detect signs of extreme stress by being alert for patients whose behavior varies from that previously observed or who cannot focus or follow directions.

Your role during many emergency situations may be to keep victims and their families and friends calm. You can promote calmness by listening carefully and giving your full attention. Your first priority, at all times, is the victim's well-being. If he is very distraught, for example, hold his hand while the doctor examines him. If one of his relatives is crying and causing him to become emotional, suggest that the relative do something to help—for example, fill out paperwork in another room.

You may face special challenges when communicating with victims during emergencies. Victims may not speak your language, or they may have a visual or hearing impairment. In such instances, follow these guidelines:

- Use gestures throughout the process for non-English-speaking victims. Continue to speak, however, because they may be able to understand some English.
- Tell patients who have visual impairments what you are going to do before you do it, and maintain voice and touch contact while caring for them.
- Ask patients who have hearing impairments whether they can read lips. If they can, speak slowly to them and never turn away while you are speaking. If they cannot read lips, communicate by writing and using gestures. At all times, try to remain face to face and keep direct physical contact.

► Educating the Patient

LO 57.8

During minor medical emergencies, after major emergencies have been resolved, and during routine office visits, you can educate patients about ways to prevent and handle various medical emergencies. For example, you might tell them how to contact the local American Red Cross office, post notices of upcoming classes the Red Cross offers, and encourage patients and family members to learn basic first aid. You also might develop a first-aid kit checklist and make it available to patients and families.

Make sure all family members, including children, are familiar with the local EMS system and know how to contact it in an emergency. Suggest that families keep emergency numbers by the telephone. In addition, teach parents how to childproof their home for children of various ages. Remember, childproofing differs for different children—for example, for children who can crawl as opposed to children who can walk.

Provide brief, easy-to-read handouts to reinforce the information you present to patients. Prepare handouts in multiple languages if you provide care for non-English-speaking patients. Find and use patient education resources for the types of patients seen by the practice. For example, if you

work in an obstetric office, obtain educational materials for pregnant and postpartum patients from companies that provide pregnancy-related products. Ask company representatives what materials are available. Many companies provide free videos and booklets.

► Disasters and Pandemics

LO 57.9

Your skills in dealing with emergencies, including first-aid and CPR training, will be an enormous help to your community in the event of a disaster or pandemic illness. To be fully effective, you also must be familiar with standard protocols for responding to disasters and pandemic illness. Table 57-6 shows ways you can help in certain types of disasters. You may even want to participate in fire or other disaster drills to familiarize yourself with emergency procedures.

Evacuation and Shelter-in-Place Plans

Every office should have evacuation and shelter-in-place plans in the event of an emergency. **Shelter-in-place** refers to an interior room or rooms within your medical facility that has few or no windows and is a place to take refuge. Plans should include means of communication for employees during and after the emergency. Maps of the facility with escape routes clearly marked should be posted. These plans should be in writing and there should be periodic practice drills. Employees should be trained in shelter-in-place procedures and their roles in implementing them. If a shelter-in-place option is a part of your emergency plan, be sure to implement a means of alerting your employees to shelter-in-place that is easy to distinguish from alerts used to signal an evacuation.

Pandemic Illness

A rapidly spreading influenza outbreak can overwhelm your office's resources very quickly. The influenza virus is capable of mutating, creating novel strains. Since the population has never been exposed to a novel influenza strain, no one has immunity to the new strain and the virus can spread quickly throughout the world. You must plan for pandemic illness before it occurs. Your office should have a written plan that includes

- Identification and isolation of patients with potential influenza.
- Communication and reporting.
- Occupational health.
- Education and training of patients and staff.
- Respiratory hygiene.

In the most serious scenario, a worldwide influenza outbreak may last 12 to 24 months. There may be waves of illness that come and go every 6 to 8 weeks. Vaccines may be unavailable at first and antivirals will likely be in short supply. To reduce confusion, essential personnel and their roles should be clearly defined. The practice's plan should be flexible, as it is likely the situation will rapidly change. Having a flexible plan will more easily accommodate an evolving pandemic. For more information, see the *Caution: Handle with Care* feature.

TABLE 57-6 Assisting in a Disaster

Type of Disaster	Action to Take
Weather disaster, such as a flood or hurricane	• Report to the community command post. • Have your credentials with you. • Receive an identifying tag or vest and assignment. • Accept only an assignment that is appropriate for your abilities. • Expect to be part of a team. • Document what medical care each victim receives on each person's disaster tag.
Office fire	• Activate the alarm system. • Use a fire extinguisher if the fire is confined to a small container, such as a trash can. • Turn off oxygen. • Shut windows and doors. • Seal doors with wet cloths to prevent smoke from entering. • If evacuation is necessary, proceed quietly and calmly. Direct ambulatory patients and family members to the appropriate exit route. Assist patients who need help leaving the building.
Bioterrorist attack	• Be alert for rapidly increasing incidence of disease in a healthy population (clusters). • Take appropriate isolation precautions. • Use standard precautions when cleaning/decontaminating patient rooms and equipment. • Inform local health departments of suspected bioterrorism agent.
Chemical emergency	• Don appropriate PPE to avoid secondary contamination. • Identify the chemical if possible and report to the local authorities. • Determine if there is a protocol for the specific chemical, if known. • Assist with patient decontamination. • Monitor patient's CABs and vital signs if indicated. • Document what medical care each victim receives. • Arrange for patient transport if possible.
Radiation emergencies	• Assess for contamination (contact with radioisotope released in liquid or power form) or exposure from an external source (for example, from a nuclear power plant accident). • If victim is contaminated, use PPE appropriate for radiation protection, assess for amount of contamination, and decontaminate victim following approved decontamination procedures. • If victim is exposed, look for signs of acute radiation syndrome (ARS) and assist physician in management of multisystem ARS symptoms.
Mass casualties	• Assess the situation for safety. • If there is an explosion, do not go toward the explosion. • Report to the community command post. • Triage victims as necessary. • Render first aid as required. • Document what medical care each victim receives.

Chemical Release Disasters

Whether a chemical release is the result of an industrial or transportation accident or an intentional release during a terrorist event, the results can quickly overwhelm emergency services and medical facilities. As a medical assistant, you may be asked to assist in treating and decontaminating patients exposed to chemicals released into the atmosphere. There are numerous chemicals that, when released into the atmosphere, can cause serious health concerns. Initial decontamination and assessment will most likely occur at the site of the release. Ambulatory patients who may need further decontamination and supportive care may be transferred to your medical facility. It is important that you use appropriate

PPE and follow specific instructions based on the chemical that is released. Decontamination is often the same for most chemicals. Removing contaminated clothing and washing the area with soap and water or flooding with water for various periods of time are standard procedure. Procedure 57-8, at the end of this chapter, outlines the steps for assisting during a chemical release emergency.

Bioterrorism

LO 57.10

Bioterrorism is the intentional release of a biologic agent with the intent to harm individuals. The Centers for Disease Control and Prevention (CDC) defines a biologic agent as a

CAUTION: HANDLE WITH CARE

Planning and Implementing a Preparedness Plan for Pandemic Illness

Even a normally smooth-running medical office can quickly become a shambles during a significant influenza outbreak. The office will most likely be short staffed due to illness while the population of sick patients increases dramatically. You must be prepared for dealing with a surge of patients, decreasing numbers of staff, and dwindling supplies. The US Department of Health and Human Services recommends developing a plan that includes the following information:

- Communication
 - Identify points of contact (most likely state and local health departments).
 - Assign a point person for external communications to ensure consistent communication.
 - Keep lists of healthcare facilities and their points of contact (hospitals, home healthcare agencies, social services, EMS, laboratories, Red Cross).
- Isolation and containment
 - Use phone triage of patients to determine who should be seen.
 - Cancel nonessential patient appointments.
 - Use block scheduling for flu versus nonflu patient care.
 - Implement a respiratory hygiene plan, including
 - Posting cover-your-cough signs.
 - Distributing masks to ill patients.
 - Providing tissues and hand hygiene products in convenient locations.
 - Establish a vaccine priority list for staff and patients.
- Education and training
 - Designate a person to coordinate training.
 - Implement infection control training for staff and patients.
 - Provide patient literature regarding home care for ill family members.
- Occupational health policies
 - Develop a nonpunitive sick leave policy.
 - Determine how to handle staff who become ill at work.
 - Determine when staff may return to work after recovering from flu. When symptomatic but well enough to work, staff may return to work.
 - Determine how to deal with staff who need to care for sick family members.
 - Develop a system for evaluating symptomatic staff prior to beginning work.
 - Manage staff at increased risk for flu complications (pregnant or immunocompromised staff).
 - Provide staff's seasonal flu vaccination.
- Surge capacity plan (dealing with resource shortages)
 - Manage staffing shortages.
 - Encourage staff to establish a family care plan.
 - Establish the minimum number of staff necessary to keep the office open.
 - Anticipate consumable resource needs (masks, gloves, hand hygiene products, and so on).
 - Plan for addressing supply shortages.
 - Plan for stockpiling at least a week of supplies at first sign of pandemic illness in the United States.

weapon when it is easy to disseminate, has a high potential for mortality, can cause a public panic or social disruption, and requires public health preparedness. Numerous biologic agents are identified as weapons, including anthrax, tularemia, smallpox, plague, and botulism. The CDC maintains an Internet site with current information about identified biologic agents at <http://www.bt.cdc.gov>.

Physicians' offices will be on the front lines if a biologic agent is intentionally released. It will be up to physicians and their staff to sound the alarm to public officials that something may be amiss. Physicians and medical assistants should be vigilant about cases that present themselves, as well as common trends in syndromes. Be on the lookout for unusual patterns in affected patients. Indications of a bioterrorist attack might include many patients having been in the same place at the same time or an unusual distribution for common illnesses, such as an increase in chickenpox-like illness in adults that might be smallpox.

If you suspect that bioterrorism is responsible for an illness, report your suspicions to the physician. It is the responsibility of your facility to immediately contact the local public

health department. The information about the patient should be recorded and appropriate tests should be performed. The laboratory should be notified of the potential for bioterrorism. Additionally, consultations with specialists and discussions of all findings are necessary when bioterrorism is suspected. The following is a list of clues of a bioterroristic attack, as defined by the American College of Physicians–American Society of Internal Medicine (Source: Epidemiological Clues of a Bioterroristic Attack: Clinical Information, Bioterrorism and Disaster Preparedness. Pocket Guide. Used with permission from American College of Physicians. ©American College of Physicians–American Society of Internal Medicine.):

- Unusual temporal or geographic clustering of illness
- Unusual age distribution of common disease, such as an illness that appears to be chickenpox in adults but is really smallpox
- A large epidemic with greater caseloads than expected, especially in a discrete population
- More severe disease than expected

- Unusual route of exposure
- A disease that is outside its normal transmission season or is impossible to transmit naturally in the absence of its normal vector
- Multiple simultaneous epidemics of different diseases
- A disease outbreak with health consequences to humans and animals
- Unusual strains or variants of organisms or antimicrobial resistance patterns

During a disaster, you may be asked to assist with various tasks. It is essential that you remain calm and follow instructions from your healthcare practitioner and local emergency personnel. Always protect yourself from injury during a disaster by assessing the situation, wearing appropriate PPE, and following OSHA guidelines at all times. You will be of no help in an emergency if you become a victim of the disaster by not following standard safety procedures.

PROCEDURE 57-1 Stocking the Crash Cart

Procedure Goal: To ensure that the crash cart includes all appropriate drugs, supplies, and equipment needed for emergencies

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Protocol for or list of crash cart items, crash cart

Method:

1. Review the office protocol for or list of items that should be on the crash cart.
2. Verify each drug on the crash cart and check the amount against the office protocol or list. Restock those that were used and replace those that have passed their expiration date.

RATIONALE: *Drugs on the crash cart should be available in quantities sufficient for use during an emergency. An out-of-date drug is of no use in an emergency.*

Some typical crash cart drugs are listed here:

- Activated charcoal
- Adenosine
- Atropine
- Calcium
- Dexamethasone
- Dextrose 50%
- Diazepam (Valium®)
- Digoxin (Lanoxin®)
- Diphenhydramine hydrochloride (Benadryl®)
- Epinephrine, injectable
- Furosemide (Lasix®)
- Glucagon
- Glucose paste or tablets
- Insulin (regular or a variety)
- Intravenous dextrose in saline and intravenous dextrose in water
- Isoproterenol hydrochloride (Isuprel), aerosol inhaler and injectable
- Lactated Ringer's solution
- Lidocaine (Xylocaine®), injectable
- Methylprednisolone tablets

- Narcan®
- Nitroglycerin tablets
- Phenobarbital, injectable
- Phenytoin (Dilantin®)
- Saline solution, isotonic (0.9%)
- Sodium bicarbonate, injectable
- Sterile water for injection

3. Check the supplies on the crash cart against the list. Restock items that were used and make sure the packaging of supplies on the cart has not been opened.

RATIONALE: *Items on the cart must be available and ready for use at the time of an emergency.*

Some typical crash cart supplies are listed here:

- Adhesive tape
- Constricting band or tourniquet
- Dressing supplies (alcohol wipes, rolls of gauze, bandage strips, bandage scissors)
- Intravenous tubing, venipuncture devices, and butterfly needles
- Personal protective equipment
- Syringes and needles in various sizes

4. Check the equipment on the crash cart against the list and examine it to make sure it is in working order. Restock missing or broken equipment.

RATIONALE: *There is no time during an emergency to make sure equipment works.*

Some typical crash cart equipment is listed here:

- Airways in assorted sizes
- Ambu-bag, a breathing bag used to assist respiratory ventilation
- Automated external defibrillator (electrical device that shocks the heart to restore normal beating)
- Endotracheal tubes in various sizes
- Oxygen tank with oxygen mask and cannula

5. Check miscellaneous items on the crash cart against the list and restock as needed. Two typical crash cart items are listed here:

- Orange juice
- Sugar packets

PROCEDURE 57-2 Performing an Emergency Assessment **WORK // DOC**

Procedure Goal: To assess a medical emergency quickly and accurately

OSHA Guidelines:

Materials:

Patient's chart/progress note, pen, gloves, and other PPE appropriate to the situation

Method:

1. Put on gloves.
2. Form a general impression of the patient, including his level of responsiveness, level of distress, facial expressions, age, ability to talk, and skin color.
3. If the patient can communicate clearly, ask what happened. If not, ask someone who observed the accident or injury.
4. Assess an unresponsive patient by tapping on his shoulder and asking, "Are you OK?" If there is no response, proceed to the next step.

RATIONALE: *You must know if a patient is unresponsive before proceeding. The patient's responsiveness will determine if you need to assess his circulation, airway, and breathing.*

5. Assess the patient's circulation, airway, and breathing. Perform CPR as needed.
6. Is there any serious external bleeding? Control any significant bleeding.
7. If all life-threatening problems have been identified and treated, perform a focused exam. Start at the head and perform the following steps rapidly, taking about 90 seconds.
 - a. Head: Check for deformities, bruises, open wounds, tenderness, depressions, and swelling. Check the ears, nose, and mouth for fluid, blood, or foreign bodies.

- b. Eyes: Open the eyes and compare the pupils. They should be the same size.
- c. Neck: Look and feel for deformities, bruises, depressions, open wounds, tenderness, and swelling. Check for a medical alert bracelet or necklace.
- d. Chest: Look and feel for deformities, bruises, open wounds, tenderness, depressions, and swelling.
- e. Abdomen: Look and feel for deformities, bruises, open wounds, tenderness, depressions, and swelling.
- f. Pelvis: Look and feel for deformities, bruises, open wounds, tenderness, depressions, and swelling.
- g. Arms: Look and feel for deformities, bruises, open wounds, depressions, tenderness, and swelling. Compare the arms for any differences in size, color, or temperature.
- h. Legs: Look and feel for deformities, bruises, open wounds, depressions, tenderness, and swelling. Compare the legs for any differences in size, color, or temperature.
- i. Back: Look and feel for deformities, bruises, open wounds, depressions, tenderness, and swelling. Feel under the patient for pools of blood.

RATIONALE: *Pools of blood indicate rapid hemorrhage.*

8. Check vital signs and observe the patient for pallor (paleness) or cyanosis (a bluish tint). If the patient is dark-skinned, observe for pallor or cyanosis on the inside of the lips and mouth.

RATIONALE: *A patient's status may change quickly. Checking vital signs often will alert you to any changes in the patient's condition.*
9. Document your findings and report them to the doctor or emergency medical technician (EMT).
10. Assist the doctor or EMT as requested.
11. Dispose of biohazardous waste according to OSHA guidelines.
12. Remove your gloves and wash your hands.

PROCEDURE 57-3 Foreign Body Airway Obstruction in a Responsive Adult or Child

Procedure Goal: To correctly relieve a foreign body from the airway of an adult or a child

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Choking adult or child patient. *Caution: Never perform this procedure on someone who is not choking.*

Method:

1. Ask, "Are you choking?" If the answer is "Yes," indicated by a nod of the head or some other sign, tell the patient you can help.

A choking person cannot speak, cough, or breathe and exhibits the universal sign of choking. If the patient is coughing, observe her closely to see if she clears the object. If she is not coughing or stops coughing, use abdominal thrusts.

2. Position yourself behind the patient. Place your fist against the abdomen just above the navel and below the xiphoid process.
3. Grasp your fist with your other hand and provide quick inward and upward thrusts into the patient's abdomen.

FIGURE Procedure 57-3 Step 3 Perform abdominal thrusts on a conscious choking victim.

RATIONALE: The thrust should be sufficient to move enough air from the lungs so that the object can be displaced from the airway.

Note: If a pregnant or obese person is choking, you will need to place your arms around the chest and perform thrusts over the center of the breastbone.

FIGURE Procedure 57-3 Step 3 Use a chest thrust for a choking victim who is pregnant or obese.

4. Continue the thrusts until the object is expelled or the patient becomes unresponsive.
5. If the patient becomes unresponsive, call EMS and position the patient on her back and begin chest compressions without a pulse check.

RATIONALE: A patient who becomes unresponsive is most likely not getting the necessary amount of oxygen to the brain.

6. Use the head tilt–chin lift to open the patient's airway.
7. Look into the mouth. If you see the foreign body, remove it using your index finger. **Do not perform any blind finger sweeps.**

RATIONALE: Blind finger sweeps can result in pushing the foreign body further into the airway and may cause pharyngeal trauma.

FIGURE Procedure 57-3 Step 7 If you see the foreign body, use your index finger to remove it from the mouth. Do not perform a blind finger sweep.

8. Open the airway. If the patient is not breathing, attempt a rescue breath. Observe the chest. If it does not rise with the breath, reposition the airway and administer another rescue breath. If the chest does not rise after the second attempt, assume the airway is still blocked and continue CPR.

PROCEDURE 57-4 Foreign Body Airway Obstruction in a Responsive Infant

Procedure Goal: To correctly relieve a foreign body from the airway of an infant

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Choking infant. *Caution: Never perform this procedure on an infant who is not choking.*

Method:

1. Assess the infant for signs of severe or complete airway obstruction, which include
 - a. Sudden onset of difficulty in breathing.
 - b. Inability to speak, make sounds, or cry.
 - c. A high-pitched, noisy, wheezing sound or no sounds while inhaling.
 - d. Weak, ineffective coughs.
 - e. Blue lips or skin.
2. Hold the infant with his head down, supporting the body with your forearm. His legs should straddle your forearm and you should support his jaw and head with your hand and fingers. This is best done in a sitting or kneeling position.
3. Give up to five back blows with the heel of your free hand, as shown in the figure below. Strike the infant's back forcefully between the shoulder blades. At any point, if the object is expelled, discontinue the back blows.

RATIONALE: Effective back blows may successfully dislodge the object. Having the infant's head down will allow the object to fall out.

FIGURE Procedure 57-4 Step 3 Use back blows for a choking infant.

4. If the obstruction is not cleared, turn the infant over as a unit, supporting the head with your hands and the body between your forearms.

5. Keep the head lower than the chest and perform five chest thrusts.

RATIONALE: Chest thrusts will force air out of the lungs, helping dislodge the object.

Place two fingers over the breastbone (sternum), above the xiphoid. Give five quick chest thrusts about $\frac{1}{2}$ to 1 inch deep. Stop the compressions if the object is expelled.

FIGURE Procedure 57-4 Step 5 Perform five chest thrusts.

6. Alternate five back blows and five chest thrusts until the object is expelled or until the infant becomes unconscious. If the infant becomes unconscious, call EMS or have someone do it for you.
7. Open the infant's mouth by grasping both the tongue and the lower jaw between the thumb and fingers, and pull up the lower jawbone. *If you see the object, remove it using your smallest finger. Do not use blind finger sweeps on an infant.*

RATIONALE: A blind finger sweep may push the object deeper into the airway.
8. Open the airway and attempt to provide rescue breaths. If the chest does not rise, reposition the airway (both head and chin) and try to provide another rescue breath.
9. If the rescue breaths are unsuccessful, begin CPR.
10. Open the infant's mouth and look for the foreign object. If you see an object, remove it with your smallest finger.
11. Open the airway and attempt to provide rescue breaths. If the chest does not rise, continue CPR until the doctor or EMS arrives.

PROCEDURE 57-5 Controlling Bleeding

WORK // DOC

Procedure Goal: To control bleeding and minimize blood loss

OSHA Guidelines:

Materials: Patient chart/progress note, clean or sterile dressings

Method:

1. If you have time, wash your hands and don exam gloves, face protection, and a gown.
RATIONALE: To protect yourself from splatters, splashes, and sprays.
2. Using a clean or sterile dressing, apply direct pressure over the wound.

3. If blood soaks through the dressing, do not remove it. Apply an additional dressing over the original one.

RATIONALE: Removing the dressing may dislodge a clot and cause more bleeding.

4. If possible, elevate the bleeding body part.
5. If direct pressure and elevation do not stop the bleeding, apply pressure over the nearest pressure point between the bleeding and the heart. For example, if the wound is on the lower arm, apply pressure on the brachial artery. For a lower-leg wound, apply pressure on the femoral artery in the groin.
6. When the doctor or EMT arrives, assist as requested.
7. After the patient has been transferred to a hospital, properly dispose of contaminated materials.
8. Remove the gloves and wash your hands.
9. Document your care in the patient's chart.

FIGURE Procedure 57-5 Step 5 Apply pressure on these pressure points to stop bleeding.

PROCEDURE 57-6 Cleaning Minor Wounds

WORK // DOC

Procedure Goal: To clean and dress minor wounds

OSHA Guidelines:

Materials: Patient chart/progress note, sterile gauze squares, basin, antiseptic soap, warm water, and sterile dressing

Method:

1. Wash your hands and don exam gloves.
2. Dip several gauze squares in a basin of warm, soapy water.
3. Wash the wound from the center outward, using a new gauze square for each cleansing motion.
RATIONALE: To avoid bringing contaminants from the surrounding skin into the wound.
4. As you wash, remove debris that could cause infection.

FIGURE Procedure 57-6 Step 4 Using a pair of forceps, carefully remove any large debris that could cause infection.

© McGraw-Hill Education

5. Rinse the area thoroughly, preferably by placing the wound under warm, running water.

RATIONALE: Running water will wash away debris.

FIGURE Procedure 57-6 Step 5 Rinsing the area with water or sterile saline washes debris from the wound.

© McGraw-Hill Education

6. Pat the wound dry with sterile gauze squares.
7. Cover the wound with a dry, sterile dressing. Bandage the dressing in place.
8. Properly dispose of contaminated materials and decontaminate surfaces potentially exposed to blood or other body fluid.
9. Remove the gloves and wash your hands.
10. Instruct the patient on wound care.
11. Record the procedure in the patient's chart.

PROCEDURE 57-7 Caring for a Patient Who Is Vomiting

WORK // DOC

Procedure Goal: To increase comfort and minimize complications, such as aspiration, for a patient who is vomiting

OSHA Guidelines:

Materials: Patient chart/progress note, emesis basin, cool compress, cup of cool water, paper tissues or a towel, and (if ordered) intravenous fluids, electrolytes, and an antinausea drug

Method:

1. Wash your hands and don exam gloves and other PPE.
2. Ask the patient when and how the vomiting started and how frequently it occurs. Find out whether she is nauseated or in pain.

3. Give the patient an emesis basin to collect vomit. Observe and document its amount, color, odor, and consistency. Particularly note blood, bile, undigested food, or feces in the vomit.
4. Place a cool compress on the patient's forehead to make her more comfortable. Offer water and paper tissues or a towel to clean her mouth.
5. Monitor for signs of dehydration, such as confusion, irritability, and flushed, dry skin. Also monitor for signs of electrolyte imbalances, such as leg cramps or an irregular pulse.
6. If requested, assist by laying out supplies and equipment for the physician to use in administering intravenous fluids and electrolytes. Administer an antinausea drug if prescribed.
RATIONALE: To replace fluids and electrolytes if the patient becomes dehydrated.
7. Prepare the patient for diagnostic tests if instructed.
8. Remove the gloves and wash your hands.

PROCEDURE 57-8 Assisting During a Chemical Disaster

Procedure Goal: To assist during a chemical disaster

OSHA Guidelines:

Materials: Soap, water, containment materials such as tubs or plastic covers, biohazard bags and boxes, watch with a second hand

Method:

1. Wash your hands and don exam gloves, moisture barrier gown, and other PPE appropriate for chemical released.
RATIONALE: *To reduce the possibility that you are exposed to the chemical.*
2. Assess the victim for consciousness and respiratory distress.
3. Monitor the victim's vital signs.
4. Assess the victim for chemical contamination. Look for unusual powder or stains on skin or clothing.
5. Remove the victim's contaminated clothing.
RATIONALE: *Removing the patient's clothing decreases the likelihood of further exposure to the chemical.*
6. Carefully place the clothes in a biohazard bag and seal the bag. Place the bag in a secondary box or container according to OSHA standards and label the box for disposal. Local authorities may provide labels with detailed information about the chemical.

7. Carefully brush any powder on the victim's skin off into a bag or other container, being careful not to disperse the powder into the air.
8. If you are directed to wash the affected area, place the affected body part over a tub, container, or other containment device.
9. Wash the exposed area with a surfactant detergent and large amounts of water.
10. Continue to flush the area with large amounts of water for at least 15 minutes.
11. Continue monitoring the victim's vital signs. If the victim develops difficulty breathing, alert the healthcare practitioner and place the patient in semi-Fowler's position.
12. Be prepared to arrange for transport if the victim requires additional care and facilities are available.
13. Carefully remove PPE and dispose of it properly, in accordance with OSHA standards.
14. Wash your hands and any other skin that may have been exposed to the chemical with soap and water. You may need to shower after decontaminating the victim if heavy contamination existed.
RATIONALE: *Showering removes any chemical that may have been transferred from the victim to you and reduces the possibility of your being exposed to the chemical after removing PPE.*
15. Consult with local authorities regarding disposal of waste water and the victim's clothing.

SUMMARY OF LEARNING OUTCOMES	
LEARNING OUTCOMES	KEY POINTS
57.1 Discuss the importance of first aid during a medical emergency.	Prompt and appropriate first aid can save a life, reduce pain, prevent further injury, reduce the risk of permanent disability, and increase the chance of early recovery.
57.2 Identify items found on a crash cart.	The crash cart should include all appropriate drugs, supplies, and equipment needed for emergencies. These include but are not limited to activated charcoal, atropine, dextrose 50%, epinephrine, lactated Ringer's solution, nitroglycerin tablets, and sodium bicarbonate.
57.3 Recognize various accidental emergencies and how to deal with them.	Accidental injuries you may encounter include bites and stings; burns; choking; ear trauma; eye trauma; falls; fractures, dislocations, sprains, and strains; head injuries; hemorrhaging; multiple injuries; poisoning; weather-related injuries; and wounds.

LEARNING OUTCOMES	KEY POINTS
57.4 List common illnesses that can result in medical emergencies.	Common illnesses that may cause a medical emergency include abdominal pain, asthma, dehydration, diarrhea, fainting, fever, hyperventilation, nosebleed, tachycardia, and vomiting.
57.5 Identify less common illnesses that can result in medical emergencies.	Less common illnesses you may encounter in a medical office include anaphylaxis, bacterial meningitis, diabetic emergencies, gallbladder attack, myocardial infarction, hematemesis, obstetric emergencies, respiratory arrest, seizures, shock, stroke, toxic shock syndrome, and viral encephalitis.
57.6 Discuss your role in caring for people with psychosocial emergencies.	Psychosocial emergencies in the medical office include drug or alcohol abuse, spousal abuse, child abuse, elder abuse, and rape. As a medical assistant, you may be involved in the direct care of someone suffering a psychosocial emergency, or you may arrange for his or her care at an outside agency.
57.7 Carry out the procedure for calming a patient who is under extreme stress.	A medical assistant can help calm a patient under stress by listening carefully and giving her or his full attention.
57.8 Discuss ways to educate patients about how to prevent and respond to emergencies.	Medical assistants should educate patients about ways to prevent and handle various medical emergencies by providing brief, easy-to-read handouts containing local emergency contact numbers and a first-aid kit checklist. The handouts should be prepared in multiple languages if the practice provides care for non-English-speaking patients.
57.9 Illustrate your role in responding to natural disasters and pandemic illness.	During a disaster, a medical assistant's first-aid and CPR training will be of enormous help. A medical assistant also must be familiar with standard protocols for responding to disasters and pandemic illness.
57.10 Discuss your role in responding to acts of bioterrorism.	Physicians' offices will be on the front lines if a biologic agent is intentionally released as an act of terror. You should be aware of unusual patterns of disease in patients being seen at your office. Indications of a bioterrorist attack might include many patients having been in the same place at the same time or an unusual distribution for common illnesses, such as an increase in chickenpox-like illness in adults that might be smallpox.

CASE STUDY CRITICAL THINKING

© David Sacks/Getty Images

Recall Mohammad Nassar from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. What action should you take to keep Mohammad from exposing the other patients in the reception area?
2. What precautions should his mother take?
3. Mohammad tells you he feels like he is going to vomit. How should you care for Mohammad?
4. Dr. Williams tells you the office needs to implement the preparedness plan for pandemic illness. What steps should you take?

EXAM PREPARATION QUESTIONS

1. (LO 57.3) What is the first action you should take when administering first aid for an animal bite?
 - a. Check to see if the animal has had a rabies vaccination
 - b. Clean the wound with soap and water
 - c. Call animal control
 - d. Administer tetanus toxoid
 - e. Put antibiotic ointment on the wound
2. (LO 57.3) A displacement of a bone end from the joint is a(n)
 - a. Fracture
 - b. Sprain
 - c. Dislocation
 - d. Impaction
 - e. Greenstick
3. (LO 57.3) Which of the following is a jarring injury to the brain?
 - a. Concussion
 - b. Stroke
 - c. Seizure
 - d. TIA
 - e. Aneurysm
4. (LO 57.3) When should you apply a tourniquet to a wound?
 - a. To save the limb
 - b. If medical help is less than an hour away
 - c. Only if the patient is alert
 - d. As a last resort, if bleeding cannot be stopped
 - e. Before putting pressure on a wound
5. (LO 57.5) Severe hypoglycemia is known as
 - a. Insulin shock
 - b. Diabetic coma
 - c. High blood sugar
 - d. Diabetes mellitus
 - e. Diabetes insipidus
6. (LO 57.4) The medical term for fainting is
 - a. Hypoglycemia
 - b. Epistaxis
 - c. Shock
 - d. Stroke
 - e. Syncope
7. (LO 57.5) A severe, often life-threatening allergic reaction is known as
 - a. Anaphylaxis
 - b. Bee sting
 - c. Hives
 - d. Toxic shock syndrome
 - e. CVA
8. (LO 57.10) The intentional release of a biologic agent with the intent to harm individuals is known as
 - a. Pandemic illness
 - b. Natural disaster
 - c. Mass casualties
 - d. Bioterrorism
 - e. Radiation contamination
9. (LO 57.6) Drug abuse, attempted suicide, rape, child abuse, and alcohol abuse are examples of
 - a. Common illnesses
 - b. Psychosocial emergencies
 - c. Stress-related diseases
 - d. Psychiatric diseases
 - e. Medical emergencies
10. (LO 57.3) An injury characterized by a clean, smooth cut through the skin is a(n)
 - a. Puncture
 - b. Contusion
 - c. Laceration
 - d. Abrasion
 - e. Incision

SOFT SKILLS SUCCESS

You arrive at the office the morning after a large accidental chemical release at the local fertilizer plant. Your office was utilized by emergency personnel as a decontamination station for victims with mild to moderate exposure. As you are checking the exam rooms, you notice that one of the rooms still has contaminated clothing from a victim of the chemical accident. The clothes are in the corner of the room and are not contained. What should you do?

Preparing for the World of Work

CASE STUDY

EMPLOYEE INFORMATION	Employee Name	Position	Credentials
	Reagan Patrick	Student	In training
	Supervisor	DOB	Other Information
	Malik Katahri, CMM	09/07/19XX	Applying for a position that is opening where she is finishing her applied training.

Reagan Patrick, a 25-year-old-female, is just finishing her applied training and is beginning her job search. Her applied training included venipuncture, ECG, urinalysis, assisting with exams and procedures, patient reception, insurance claim form completion, patient scheduling, and many other clinical and administrative skills. She lives in a small town

© Jose Luis Pelaez Inc./Blend Images LLC RF

but is willing to relocate. She is excited about her new career in healthcare because it is so different from her current job working as a teller at a bank.

Keep Reagan in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

LEARNING OUTCOMES

After completing Chapter 58, you will be able to:

- 58.1** Carry out professionalism in all applied training scenarios.
- 58.2** Summarize the steps necessary for obtaining professional certification.
- 58.3** Describe an appropriate strategy for finding a position.
- 58.4** Explain key factors for a successful interview.
- 58.5** Describe ways of becoming a successful employee.

KEY TERMS

- | | |
|------------------------------|------------------------|
| affiliation agreement | functional résumé |
| applied training | networking |
| applied training coordinator | portfolio |
| chronological résumé | professional objective |
| clinical preceptor | reference |
| constructive criticism | targeted résumé |

V.P.8 Compose professional correspondence utilizing electronic technology

1. General Orientation

- c. Describe medical assistant credentialing requirements and the process to obtain the credential. Comprehend the importance of credentialing
- d. List the general responsibilities & skills of the medical assistant

4. Medical Law and Ethics

- f. Comply with federal, state, and local health laws and regulations as they relate to healthcare settings

11. Career Development

- a. Perform the essential requirements for employment, such as résumé writing, effective interviewing, dressing professionally, and following up appropriately
- b. Demonstrate professional behavior

► Introduction

After completing a medical assisting program, you may be both excited and apprehensive about beginning your new career. Such a reaction is perfectly normal. In this chapter, you will learn how to maximize your applied training experience and gain the hands-on experience you need for securing a position in medical assisting. Your applied training is an opportunity for you to explore the different responsibilities required of a medical assistant. After completing this chapter, you will understand the process for becoming a nationally certified medical assistant. You also will know how to effectively begin searching for a position in medical assisting—which includes completing a résumé, cover letter, and thank-you letter—and how to form a strategic plan to secure this position. And as you explore this chapter, you will gain valuable interviewing techniques for successfully competing in the modern healthcare world.

► Training in Action

LO 58.1

An **applied training** experience is an opportunity to work in a medical facility to gain essential on-the-job experience for beginning your new career. Some schools call this training an externship, while others call it a practicum. Whether it is called an externship or a practicum, it is an opportunity to apply—in an actual medical environment—the knowledge and skills you have learned.

Most applied training is measured by hours attended, usually a minimum of 160 hours. Applied training is a mandatory requirement of fulfilling a medical assisting program in educational institutions that are accredited by the

Accrediting Bureau of Health Education Schools (ABHES) and the Commission on Accreditation of Allied Health Education Programs (CAAHEP). Some of the applied training is completed after the didactic, or academic, portion of the curriculum (for example, during the last module or semester) and some is completed during the last semester. Medical assisting applied training may be performed at physician offices, laboratories, hospitals, administrative billing offices, and clinics.

The Applied Training Process

To make the applied training process possible, the educational institution where the medical assisting student is enrolled partners with local medical facilities throughout the area. Most schools have an **applied training coordinator**, who is familiar with medical assisting and the medical community. The applied training coordinator procures applied training sites and qualifies, or assesses, them to make certain that they provide a thorough educational experience. The applied training coordinator is the liaison between the applied training site and the educational institution. A checklist is often designed to ensure that students are given a well-rounded, safe experience (Figure 58-1). Although student applied training experiences are unpaid, the student should be positive about the experience and appreciate the opportunity to train with the facility.

Applied Training Requirements Applied training sites are required to review and sign an **affiliation agreement**. The affiliation agreement states the expectations of the facility and the expectations of the student. Some examples of the expectations of the applied training site include

CLINICAL SITE ASSESSMENT	
Name of Site	_____
Address	_____
Specialty	_____ Supervisor _____
Telephone #	_____ Fax # _____
Number of Staff	_____
Administrative/clinical experience available to students <i>(check all that apply)</i>	
_____ Front office skills	
_____ Word processing skills	
_____ Measure/record vital signs	
_____ Blood drawing (venipuncture, fingersticks)	
_____ Injections	
_____ Electrocardiograms	
_____ Specimen collection/diagnostic procedures (urinalysis, blood sugar, cholesterol, etc.)	
_____ Assisting with minor surgical procedures	
I have determined that this site meets the needs of the students in the medical assisting program.	
Print name of evaluator	_____
Signature of evaluator	_____ Date _____

FIGURE 58-1 A form such as this clinical site assessment is often used by the applied training coordinator to determine if a clinical site will be appropriate for medical assisting applied training.

- In addition, the expectations of the educational institution include

- Screening** The applied training coordinator places students in applied training clinical sites. It is not uncommon for the clinical site to screen students prior to their applied training. This screening can include

- Time Sheets** Students receive time sheets to be completed on a daily basis and faxed to the educational facility at the end of every week. The **clinical preceptor** (person at the clinical site who serves as an instructor but is an employee of the site) and the student both sign the time sheet (Figure 58-2). Weekly telephone calls and site visits may be performed by the clinical coordinator or a medical assisting instructor for each student. Some schools require weekly progress reports from each student, outlining the procedures and duties the student performed during the week. Figure 58-3 provides an example of

Clinical Training Time Sheet Medical Assistant Program

Instructions:

Students are expected to attend their clinical site for a minimum of 32 hours per week and will not receive credit for more than 10 hours per day. **For shifts greater than 4 hours, you must include a 30-minute meal break.**

- _____ Complete the log daily and fax or scan it weekly to the school no later than 5 p.m. Friday.
- _____ For each day attended, please include a brief description of the duties performed.
- _____ The time sheet must be signed and dated by both the student and the clinical site supervisor.

FIGURE 58-2 Students participating in applied training complete a weekly time sheet.

this report. When students finish their applied training, the preceptors will complete a final evaluation, and the students will be graded on their performance.

Expectations of Applied Training Candidates

While in an applied training program, you are expected to be and look professional, report to the applied training site as scheduled, and display initiative and a willingness to learn.

Professionalism You are expected to conduct yourself in a professional manner at all times while attending your applied training. During this experience, you may often feel that you are being criticized by the site preceptor, but this is a normal part of learning, called **constructive criticism**. Constructive criticism is aimed at giving you feedback about your performance in order to improve that performance. You are not expected to know everything during your applied training, but you are expected to be open to suggestions and ideas.

STUDENT WEEKLY PROGRESS REPORT

This form needs to be completed and signed each week. It must be faxed or scanned with the time sheet on Friday afternoon. It is designed to help you maximize your clinical training experience. Having recognizable goals is the surest way to succeed!

Name: _____ Date: _____

Class Code: _____

Clinical Site: _____

Supervisor Signature: _____

Student Signature: _____

I. Goals for next week:

1. _____

2. _____

3. _____

II. Personal assessment of progress this week:

III. Supervisor's assessment of progress this week:

IV. Identify one task/item/event you are most proud of that occurred this week:

V. Did you meet your goals for this week? Why or why not?

FIGURE 58-3 A weekly progress report is a helpful way for students to track their applied training goals and achievements.

Asking questions during your applied training is expected, but you should not question why a procedure is done a certain way or why you are asked to do something. Do not argue with preceptors about their skills, and know that you may be exposed to some procedures that are not performed exactly as you were taught. After all, there is usually more than one way to get the desired result in patient care. Everything you do during your applied training is a learning experience and should be treated as such.

Your behavior at your applied training site is expected to be as professional as if you were an employee there. Foul language and inappropriate conversation are not tolerated in any workplace. You are expected to be professional with the patients under all circumstances. Medical facilities expect you to demonstrate empathy and compassion to every patient. Proper verbal skills and grammar are expected at all times. Do not use slang when communicating with office staff and patients.

Personal phone calls should not be made or accepted during working hours. Turn off your cell phone while at work and do not use the facility phone for personal calls. Park your car in the designated employee parking area, not in places reserved for patients. Many patients are older and have difficulty walking long distances. It is a professional courtesy and good customer practice to allow the patients to use the parking spots closest to the entrances.

Attendance You are expected to report to your applied training *every day* that you are assigned to a schedule. It is your responsibility to have several alternatives for baby-sitting and transportation. Employers are seeking dependable and punctual medical staff and do not tolerate attendance problems with their own staff, nor do they expect it from their applied training students. Chronic attendance and punctuality issues can be grounds for termination of your applied training. In the event of an emergency, you are expected to call the

medical facility and the school 2 hours before the beginning of your shift, as would any other employee.

As a medical assisting student doing your applied training, also be sure to adhere to the facility's policy regarding breaks. Take breaks only when it is appropriate to do so. If you smoke, refrain from smoking during work hours, smoking only in designated areas if allowed. Many medical facilities are now considered no-smoking zones and smoking is prohibited on the grounds. Lunch breaks are permitted under facility policies. Be sure to adhere to break and lunch time frames, returning back to work on time.

Professional Appearance Medical facilities expect you to appear as a medical professional. Most facilities require a uniform that consists of a scrub top and bottom and a lab jacket. Your scrubs should be clean, pressed, and well fitting. Shoes should be clean, white, and in good repair. Your name tag or badge should always be worn and visible to patients. Nails should be trimmed and clean. Many medical facilities will not accept students with artificial nails. Facial and tongue piercings are not acceptable when working with patients, and visible tattoos must be covered. Your hair should be a natural color and pulled back from your face and off your collar. Makeup should be conservative and in good taste. Perfumes, colognes, scented shampoos, hair gels, and hairsprays should not be used because patients with respiratory conditions or allergies may not be able to tolerate them.

Remember that as a medical assisting student conducting your applied training, you represent several things:

- The school you attend. It is important to maintain a good reputation in the medical community. You will depend on the school's reputation to obtain a job.
- The profession of medical assisting. Participating in a medical assisting applied training program gives you an opportunity to represent the profession of medical assisting to patients and the community.
- Yourself. First impressions are lasting impressions. Make your first impression to the medical community an outstanding one. Even if you are not offered a position there, or if the site is not one where you would like a permanent position, the office will be able to give you your first professional reference and may be key to your obtaining your first position as a medical assistant.

Initiative and Willingness to Learn During your applied training, accept all assignments with enthusiasm and grace, no matter how mundane. These tasks are often a test of how well you accept assignments and work within a medical team. Ask for additional work if you are idle and look for tasks that need to be done. Keep a notebook and record the office policies and procedures. Be prepared to observe and participate in all office policies and procedures.

Make a Good Impression Often, a shy and passive medical assisting student in applied training will appear to the preceptor and facility as unmotivated or lacking initiative. It is important to be assertive and confident when working in

healthcare. Remember: Every day on your applied training is "show time"! You may have to step out of your comfort zone to make a good impression.

► Obtaining Professional Certification

LO 58.2

Once you complete your education, you may be eligible to take a national certification exam. Some employers require—and many prefer—a medical assistant who is certified. Holding a medical assisting credential can make you more desirable in a competitive job market and enhance the possibilities of career advancement once you are hired. There are two major credentialing agencies: the American Association of Medical Assistants (AAMA) and the American Medical Technologists (AMT). The CMA (AAMA) exam is offered by the Certifying Board of the AAMA and the RMA exam is offered by the AMT. Each of these agencies has its own specific exam eligibility requirements.

Certification Qualifications

In order to sit for a national certification exam, you must meet certain criteria. Both agencies require that you be of good character, including having no felony convictions or guilty pleas to felonies. Other eligibility requirements include

- AAMA—graduation from a CAAHEP- or ABHES-accredited medical assisting program. If you are a student in a program accredited by either of these agencies, you may take the test up to 30 days prior to graduation or within 12 months after graduation.
- AMT—graduation from an ABHES- or CAAHEP-accredited medical assisting program or from a program at a college with regional accreditation and at least 720 clock hours of medical assisting skills training. If you have formal US Armed Forces medical services training, you are also eligible to take the RMA exam. In addition, someone with at least 5 years of experience working as a medical assistant may take the RMA exam.

Applying for the Exam

Once you determine that you are eligible for national certification, you must apply to take the exam. There are required fees for each exam and both require completion of an application form. The following are the steps for applying:

1. Request an application from the appropriate agency.
2. Gather required documents.
3. Review all exam policies and procedures in the examination handbooks.
4. Complete the application and submit it to the appropriate agency.
5. Schedule an exam time.

Be sure to provide all the required information when completing the application. Submitting an incomplete application will delay your taking the exam, which could affect the timing of your job search.

Preparing to Take the Exam

Taking the time to prepare will increase your chances of successfully completing the exam, so never try to take the exam without knowing the following:

- Test format. The CMA (AAMA) exam is a computer-based test. The RMA is either computer-based or paper-and-pencil.
- Content areas. This gives you general information about the material covered on the test.

General Content Areas When you begin studying for the exam, a good starting point is to know the content it covers. The areas of knowledge you should be familiar with for either exam are general medical, which includes medical terminology, anatomy and physiology, medical ethics and law, and human behavior; administrative; clinical; and laboratory. These general areas are expanded further in the content outlines available from the AAMA or AMT. Use the expanded content outlines as a study guide, making sure you review materials from each specific content area.

Study Tips At first, studying for a national exam can seem like an impossible task. You may feel overwhelmed, with no idea where to start or what to do. Do not panic. Instead, break it down. You cannot study everything at once, so you must find a way to make it manageable. If you are served a 12-ounce steak, you would not put the entire steak in your mouth and try to chew it. What would you do? Cut it into pieces. That is exactly what you need to do when studying for the certification exam. Study a piece at a time.

Start by taking a practice exam that covers all the content areas of the real exam. This will reveal your areas of weakness. Use this information to focus your studies on what you do not know. Students often make the mistake of studying what they do know because it feels good, but this will not help you in the long run. If you study what you do not know, you will ultimately spend less time studying. Once you have studied the content in your areas of weakness, take another practice test. You will most likely score higher on the second practice test. Identify the areas you are still having trouble with and study the content in those areas. You will soon feel comfortable with the information in all areas.

During your study process, follow these general guidelines:

- Start early; do not wait until a few days before the exam. Cramming does not work.
- Study some every day.
- Create a study schedule and follow it.
- Study in a quiet place free of distractions. Turn off your phone while you are studying; most calls can wait until you are finished.
- Make flash cards with terms, definitions, and concepts.
- Use mnemonic devices to help you remember difficult material. For example, if you are learning the stages of mitosis, in order, remember the first letter of each phase: IPMAT—interphase, prophase, metaphase, anaphase, telophase.

The Day of the Test This is the time to show your knowledge. You have followed your study plan and you are ready. Now, make the best of all that studying by getting a good start on the day. To prepare for test day,

- Get a good night's sleep the night before the test. Remember, do not cram—it does not work and just tires out your brain.
- Eat a balanced breakfast. Your brain, like your car, needs fuel.
- Take a short walk if you can. Exercise helps your brain as well as your body.
- Give yourself enough time to get to the testing site and make sure you know exactly where it is. Use a map if necessary.
- Take all necessary documents to the testing site. Do not forget your photo ID. You will have to identify yourself.
- If you are taking a paper-and-pencil test, take more than one pencil with you.
- Tell yourself that you are prepared. Believing in yourself is essential.

► Preparing to Find a Position

LO 58.3

The next phase of beginning your new career is seeking a position as a medical assistant. Most accredited schools have a career services department. Its primary focus is job placement after graduation. The department's counselors will assist you in writing your résumé, improving your interviewing skills, and learning about positions in your field. Many employers will contact a school's career services department to recruit medical personnel.

Seeking Employment

In addition to working with a career services department, you can take advantage of a number of other resources in seeking employment within the medical assisting field. These resources include Internet sites, classified ads, employment services, and networking with classmates and others.

Internet Sites and Classified Ads Many prospective employers use employment websites and classified advertisements in area newspapers to alert potential applicants to a career opportunity with their organization. The job listing or advertisement usually describes the position's duties and responsibilities as well as the type of education and experience preferred.

When you are first beginning to seek a medical assisting position, do not become discouraged if you see advertisements asking for a specified amount of experience, such as 2 years. You must realize that employers place ads seeking an experienced candidate, but many will consider a new graduate because experienced candidates are not always available. Becoming credentialed will help you bridge this experience gap. A local newspaper's classified advertisements and corresponding website are often a good place to start your search. You also might check for a medical practice network website

in your area. These often have lists of local medical practices along with job postings for these practices. They may allow you to submit online job applications.

It is important to explore all the possibilities when seeking employment opportunities. A medical assistant is qualified for a number of positions. For example, new graduates can apply for the following positions:

- Unit secretary in hospitals
- Phlebotomist in labs
- Patient care associate or patient care technician in hospitals
- Entry-level medical coder and biller
- Customer service representative in medical-related companies
- Clinical or administrative positions in physician offices and clinics

The Internet is another useful tool when seeking employment. Websites for job seekers are becoming more and more popular, as they allow job seekers to post résumés online and to respond to advertisements that are posted by employers locally or statewide. Many hospitals and larger companies will not accept paper or faxed résumés; instead, they require all applicants to fill out an electronic application and post résumés on the facility website. Newly graduated medical assistants should post their résumé and cover letter on all local hospital and physician network websites and on local employment websites during their applied training to start circulating their résumés.

Employment Services Employment and temporary agencies provide assistance in locating a specific job. Both types of agencies have a variety of job openings on file. You should call to make an appointment with an employment counselor. Agencies usually require you to fill out an application, take a basic healthcare knowledge test, and provide a résumé. If the agency has positions that match your skills, it contacts the employer. If the service has no appropriate listings, it will place your résumé on file.

Employment services are an excellent way to gain experience and select a position. You are given an opportunity to try out the office or facility with little commitment on your part. Many permanent opportunities can result from a temporary job assignment.

Networking **Networking** involves making contacts with relatives, friends, and acquaintances who may have information about how to find a job in your field. People in your network may be able to give you job leads or tell you about openings. Word-of-mouth referrals—finding job information by talking with other people—can be very helpful. Other people may be able to introduce you to others who work in, or know people who work in, your field. You also may find opportunities at your applied training site. Although there might not be a position available directly within your site, the practice manager may know someone who is looking for a medical assistant. Networking is a valuable tool. It can advance your career even while you are employed.

Joining a medical assisting organization and attending conferences are the easiest ways to network. Attend an organization's local chapter meetings, such as the AAMA county or state chapters, and talk with as many people as possible. Always take along a pen and a notebook. Be prepared to exchange information with other attendees. Remember, networking is an exchange of information—it is not one-sided. What you learn through networking may enable you to provide others with information to help their job search or further their career.

Your classmates are often a good source of networking. It is important to build lasting friendships with your classmates and keep in touch after graduation. Oftentimes, they will know of positions as they gain employment. Networking begins in the classroom.

Creating a Résumé

Your résumé is a vital part of the employment process. It provides potential employers with information about your educational and work history and other aspects of your background.

Components of a Résumé In order to create a well-rounded, informative résumé, you need to include a wide variety of information about your background.

Personal Information Include your name, address, telephone number, cell phone number, and e-mail address. Do not include your marital status or the number of children you have. You should not include your height, weight, interests, or hobbies unless you think they are relevant to the position.

Professional Objective A **professional objective** is a brief, general statement that demonstrates a career goal. An example of an effective, professional objective is the following: "To work as a medical assistant, applying skills in patient relations and laboratory work while gaining increasing responsibility." If you want to list a specific career objective, such as applying your medical assisting skills in a pediatric medical facility, it would be best to mention it in the cover letter and not on your résumé.

Employment Experience List the title of your most recent or last job first, the dates you were employed there, and a brief description of your duties. Choose jobs that have been the most beneficial to your working career. Do not clutter your résumé with needless details or irrelevant jobs. You can elaborate on specific duties in your cover letter and in the interview. Only include jobs you have held for a longer period of time, such as 6 months to a year.

Educational Background In providing your educational history, list your highest degree first, the school attended, the dates, and the major field of study. Include educational experience that may be relevant to the job, such as certification, licensing, advanced training, and intensive seminars. Do not list individual classes on your résumé. However, do list the skills you acquired during your training, such as phlebotomy, CPT, and coding skills. If you have taken classes that relate directly to the job you are seeking, list them in your cover letter.

Awards and Honors List the awards and honors related to your career or that indicate excellence. Perfect attendance, academic honors, and student-of-the-month are excellent traits that employers are seeking. Highlight this information prominently rather than writing it as an afterthought. You can make the most impact by displaying your best qualities at the beginning of this section.

Campus and Community Activities List activities that show leadership abilities and a willingness to contribute. Include any volunteer work.

Professional Memberships and Activities List any career-related professional memberships. Student memberships are available through the American Medical Technologists (AMT) and the American Association of Medical Assistants (AAMA). You can contact the AMT and request a copy of the student by-laws and directions on how to form a student membership in your school. The AAMA provides continuing education through its local chapters and sponsors local meetings periodically throughout the year. Employers like medical professionals who are involved in their disciplines. It demonstrates a commitment and dedication to their chosen field.

Summary of Skills As you learn clinical and administrative skills, be sure to list them on your résumé. Under headings such as “Clinical Skills” or “Administrative Skills,” list the skills you acquired in school and during your applied training. The following are some examples of clinical skills:

- ECG
- Venipuncture
- Urinalysis
- Parenteral injections
- Aseptic technique and bloodborne pathogens
- First aid and bandaging
- CPR
- Triage and vital statistics
- Spirometry

Some examples of administrative work include

- CPT, HCPCS, and ICD-10 coding.
- Insurance claim form completion and reimbursement posting.
- MediSoft® billing and reimbursement software (or any software you have experience with).
- Medical office accounting practices.
- Keyboarding speed.
- Microsoft Office® (list the software you are proficient with).

Choosing a Résumé Style Three résumé styles have been developed: functional, chronological, and targeted. Each has specific advantages and disadvantages. You will want to choose a style or combination of styles that best describes your strengths and skills.

Functional Résumé A **functional résumé** highlights specialty areas of your accomplishments, strengths, knowledge, and skills. You can organize these in an order that supports your objective. Functional résumés are useful when you change careers, reenter the job market after an absence, or have had a variety of unconnected work experiences. A sample of a functional résumé is shown in Figure 58-4.

Chronological Résumé Individuals who have a strong work history use a **chronological résumé**. List your most recent job first and end with your first job. Chronological résumés are best when you stay in the same field and when your employment history shows growth and development. Do not use a chronological résumé if you have gaps in your work history, if you have changed careers, if you have been in the same job for many years, or if you are looking for your first job. Figure 58-5 illustrates a chronological résumé.

Targeted Résumé A **targeted résumé** is best if you are focused on a specific job target. The résumé should contain a clear, concise objective about what you are looking for (targeting). This résumé should tailor your descriptions of your skills, academic achievements, student honors, and other pertinent information to the job you are seeking. This approach adds substance to your résumé when you have just graduated and do not have relevant job experience. Because the targeted résumé is an academic-type résumé, your skills, achievements, and community and volunteer work—your most significant assets—should be listed first. A sample of a targeted résumé is shown in Figure 58-6.

Writing the Résumé

One of the most daunting tasks of completing the résumé process is writing the résumé. Résumé writing is different from any other form of writing. The language you use in your résumé will affect its success, so it is important to be careful and conscientious when choosing your words.

You should use a direct, functional writing style that focuses on the use of verbs and other words that imply action on your part. Translate the facts of your academic and employment history into an active and precise résumé that will keep the reader’s interest and highlight your major accomplishments in a concise, effective manner.

Writing with action words and strong verbs portrays you as an energetic, active person who is able to achieve results in your work. Choose words that display your strengths and demonstrate your initiative. Table 58-1 provides a list of commonly used verbs that help create a strong, active résumé.

The following are two writing samples that differ only in their style. The first example is ineffective because it does not use action words to accent the applicant’s work experiences.

Example #1 WORK EXPERIENCE

Medical Assistant

Manager of eight medical assistants from three offices. Office manager of three offices located east and west sides. In charge of the daily operations of the medical office. Trainer of all new medical assistants.

Donna Turner-Smith
18 Kingsley Road
Olmsted Falls, OH 44138
(440) 555-4279

PUBLIC HEALTH EDUCATION:

Instructed community groups on HIV awareness
Instructed volunteers on how to set up community programs on domestic violence
Facilitated workshops for parents of teenagers
Provided in-services for public school teachers on signs and symptoms of substance abuse

COUNSELING:

Consulted with social workers on individual cases for suspected child abuse
Worked with parents from abused homes
Counseled individual abused children

ORGANIZATIONAL:

Wrote grants for federal funds for HIV awareness programs
Served as a liaison for transitional shelters for victims of domestic violence
Served as a liaison between community health agencies and public schools

PROFESSIONAL WORK HISTORY:

2006–2011 Project SAFE, Plymouth, Michigan
 HIV Public Health Instructor

2011–2012 Department of Child Health and Safety, Cleveland, Ohio
 Public Health Educator

EDUCATION:

2006 BS Sociology, Eastern Michigan University, Ypsilanti, Michigan

References available upon request

FIGURE 58-4 A functional résumé is often used by people who are reentering the job market.

Special Projects: Coordinator and secretary for Cuyahoga County Chapter of the American Association of Medical Assistants.

Accomplishments: Daily patient census went up 25% by implementing the “Patient First” customer service program. Patient-facility relations improved.

In the second example, the first paragraph has been rewritten. Notice how the tone has changed. The paragraph now makes the applicant sound stronger and more active. This person accomplished goals.

Example #2
WORK EXPERIENCE

Medical Assistant

Managed eight medical assistants from three different offices. Oversaw three offices in the Greater Cleveland area. Directed the daily operations of the medical offices. Coordinated events and served as secretary for the Cuyahoga County Chapter of the American Association of Medical Assistants. Increased daily patient census by 25% due to the success of a customer service model, “Patient First,” which improved patient-facility relations during my tenure.

Anthony Dalton
1234 West 25th Street
Park Ridge, NJ 07656
(201) 555-8311

WORK EXPERIENCE:

September 2010–Present NORTH BERGEN CLINIC FOUNDATION

Lead medical assistant for cardiology practice
Patient preparation
EKG and Holter monitor
Assist with stress testing
Patient follow-up

June 2002–August 2010 ST. JOSEPH HOSPITAL

Phlebotomist—inpatient and outpatient

March 2002–June 2002 ST. JOSEPH HOSPITAL

Medical assisting externship
Administrative and clinical responsibilities utilizing all
medical assisting skills in the emergency department

- Patient triage
- Foley catheters
- ECG
- Specimen collection
- Patient intake
- Insurance verification

EDUCATION AND CERTIFICATIONS:

Associate of Applied Science Degree, June 2008, Bergen Community College,
Paramus, New Jersey, 07645

Certified Medical Assistant, August 2002

Résumé Writing Tips

Pay close attention to detail as you create your résumé:

- Organize your information by using a worksheet (Figure 58-7). List all the addresses, dates, phone numbers, and supervisors of previous positions you have held. Write down brief descriptions of all the responsibilities and duties of your positions.
- List your educational institutions and their addresses, your dates of attendance, and the type of diploma or degree, including your major.
- Choose a résumé format that best describes your experience, education, and achievements.
- Use a word processing program and save your résumé so that you can update it as needed.
- Proofread all spelling and grammar. Your completed résumé should be perfect. Do not rely on the spell-checking feature of your computer. Proofread your résumé line by line and request that someone else also proofread your résumé.
- Select a high-quality, standard-size (8½ × 11) résumé paper with a weight between 20 and 25 pounds. Use ivory or white paper with matching envelopes.

Kelly Adamson
220 Terrace Avenue
Mooreburg, TN 37811
(423) 555-2657

CAREER OBJECTIVE:

To obtain a challenging position as a medical assistant in a growth-oriented ambulatory care facility

ACHIEVEMENTS:

Registered Medical Assistant
Certified Phlebotomy Technician
Registered Medical Office Specialist
Graduate of an Accredited Medical Assistant Program
OSHA Compliance Officer
American Heart BLS Instructor

SKILLS AND CAPABILITIES:

Front Office and Clinical Medical Assistant Patient Triage
Specimen Collection Venipuncture
ECG and Holter Monitor Parenteral Injections
ICD-9 and CPT Coding Medical Billing

PROFESSIONAL EXPERIENCE:

September 2011–Present Affiliated Physician Network, Mooreburg, Tennessee
Medical Assistant/Office Coordinator
June 2001–September 2011 Partners in Internal Medicine, Mooreburg,
Tennessee Medical Assistant

EDUCATION:

Sanford Brown Institute, Diploma, Medical Assisting 2006

AFFILIATIONS:

American Medical Technologists

References available upon request

FIGURE 58-6 A targeted résumé is often used by a person who is focusing on a specific job target.

- Use clear and concise statements and sentences. Your writing should reflect a positive and confident tone. For example, if you are describing your duties as a food service worker, use sentences that focus on customer service, cash management, and the training and development of new food service workers. Avoid using the word “I” because the reader already knows that the résumé is referring to you.
- Be truthful about your strengths and abilities. Do not mislead or exaggerate any skills, talents, or experience.

Procedure 58-1, at the end of this chapter, provides information on how to write a résumé.

Writing a Cover Letter

A cover letter is an introduction to your résumé. It is a tool that markets your résumé as well as your skills and abilities. Your cover letter is just as important as your résumé in your job search. An effective cover letter motivates an employer to review your résumé and perhaps grant you a job interview.

Your cover letter should be direct and to the point. It should be no longer than one page and typed on paper that matches your résumé. If possible, your cover letter should be addressed to a specific person in the organization. You can call the facility and ask to whom you should address the letter.

TABLE 58-1 Effective Résumé Verbs

administered	inspected
advised	introduced
analyzed	maintained
billed	managed
carried out	motivated
compiled	negotiated
completed	operated
conducted	ordered
contacted	organized
coordinated	oversaw
counseled	performed
designed	planned
developed	prepared
directed	presented
distributed	produced
established	reviewed
functioned as	supervised
implemented	taught
improved	trained

If a name is not available, it is acceptable to address the letter to “Human Resources Manager” or “Recruitment Manager.” Research the facility prior to writing the letter. This information can help you tailor your letter to show how your qualifications and interests directly relate to the needs of the company or medical facility. Make sure the description of your qualifications and interests reflects the words the company used in its advertisement. Always be truthful about the information in the cover letter; employers often verify all facts presented in your résumé and cover letter. Check each cover letter for errors in spelling, grammar, and punctuation. The format for a cover letter is shown in Figure 58-8.

Sending a Résumé

When mailing a résumé, make sure you have the correct name, address, and zip code of the facility. This information should be typed on a matching envelope. Many software programs have an envelope template feature that allows you to print an envelope using the address in your cover letter. Do not handwrite envelopes; professionally appearing mail is often opened first. Make sure that you attach sufficient postage.

If you fax a résumé, verify the fax number and person or department you are faxing to. Make sure your name is on all the faxed pages. If your fax machine provides a completion printout, save it to verify that the fax was delivered.

Some classified ads request that you send your résumé via e-mail. In order to send your résumé in electronic form, you must first have an account with an Internet service provider (ISP). You will be asked by the ISP to select a login or screen name. Do not use a casual name for your login; prospective

employers will see your login name in their inbox. Instead, choose a name that is conservative and professional. Verify that your e-mail was sent by checking your sent items.

Post your résumé and cover letter on the Internet by using a career job search site. Most job sites have local employers posting positions daily. A job search site will provide clear directions on how to post your résumé and cover letter. Some school career services departments host online job fairs and will assist you in posting your résumé.

Obtaining a Reference

Prior to the end of your applied training, meet with your preceptor and ask for a **reference**, a recommendation for employment from the facility and the preceptor. A reference can be in the form of a letter from the facility, preceptor, or physician or it can be a request to include these people on your reference list. It is professional to always ask before you list someone as a reference. References are important to career building because employers often like to inquire about a person prior to offering him or her employment. Your first references in medical assisting are your instructors and then the applied training facility.

You will want three to five references, including employment, academic, and character references. Ask instructors for a general letter before you finish your program. Fellow members of professional associations or your classmates can provide character references and your applied training facility can provide an employment reference. Make sure that you ask your references for permission to use their names and phone numbers. Do not print your references on the bottom of your résumé. List them on a separate sheet of paper so that you can provide them upon request, and update the list as needed.

Preparing a Portfolio

Prior to the interviewing phase, you should organize all your employment documentation into a portfolio. A **portfolio** is a collection of documents and may include your résumé; cover letter; reference list or reference letters; awards for volunteer service in a health-related field; and student recognition certificates for student-of-the-year or month, perfect attendance, or academic honors. Include a copy of your transcript, diploma or degree, and medical assisting credentials such as your CMA (AAMA) or RMA (AMT). You also can include any other certifications you hold, such as a CPR card or phlebotomy certification. Some employers request proof of immunizations, so include that in your portfolio. Give your portfolio a professional presentation by printing your documents on a high-quality printer and organizing them in a nice binder. A professional portfolio can help you obtain employment. If needed, look for a service that specializes in creating professional portfolios.

► Interviewing

LO 58.4

Preparation for your interview begins long before the interview itself. After you send your cover letters and résumés, you must make sure that prospective employers can reach you by telephone. You must practice how you are going to handle

EMPLOYMENT WORKSHEET	
Job Title	_____
Dates	_____
Employer	_____
City, State	_____
Major Duties	_____

Special Projects	_____

Accomplishments	_____

FIGURE 58-7 An employment worksheet can be a useful tool in drafting a résumé.

your interview, and you must plan what to wear and how to present yourself in the most professional way.

Before starting your job search, invest in an answering machine or set up your voicemail to receive calls when you are not available. Be sure the outgoing message is clear, concise, and professional. Avoid cute messages and background music. An appropriate message would be “I’m unable to take your call at the moment, but your call is important to me. Please leave your name and number, the time you called, and a brief message after the tone and I will call you back as soon as I can. Thank you.” Also, make sure all household members who answer the phone (especially children) know proper phone etiquette and how to take a written message. When a prospective employer calls with an interview invitation, write down the interviewer’s name and the company or practice name, day, time, and location of the interview.

Interview Planning and Strategies

Just as the résumé is important for opening the door to opportunity, the job interview is critical in allowing you to present yourself professionally and to clearly articulate why you are the best person for the job. As you learned in the *Interpersonal Communication* chapter, being successful in a medical assisting career is centered on communication—both verbal and nonverbal. These communication skills will be assets during your job interviews. The following list provides some strategies that will help you improve your interviewing skills:

- Practice interviewing. Rehearse possible questions and be prepared to answer them directly. Have a friend or family member interview you as you sit in front of a mirror and observe your body language. Your college career center may help you prepare by offering mock interviews.

Your Street Address
City, State, Zip Code

Date

Name of person to whom you are writing
Title
Company or Organization
Street Address
City, State, Zip Code

Dear Dr., Mr., Mrs., Miss, or Ms. _____,

1st Paragraph: Tell why you are writing. Name the position or general area of work that interests you. Mention how you learned about the job opening. State why you are interested in the job.

2nd Paragraph: Refer to the enclosed résumé and give some background information. Indicate why you should be considered as a candidate, focusing on how your skills can fulfill the needs of the company. Relate your experiences to the company's needs and mention results/achievements. Do not restate what is said on your résumé—pull together all the information and tell how your background fits the position.

3rd Paragraph: Close by making a specific request for an interview. Say that you will follow up with a phone call to arrange a mutually convenient interview time. Offer to provide any additional information that may be needed. Thank the employer for his/her time and consideration.

Sincerely,

(your handwritten signature)

Type your name

Enclosure

FIGURE 58-8 The object of a cover letter is to convince the recipient to read your résumé.

- Anticipate question types. Expect open-ended questions such as the following: “What are your strengths?” “What are your weaknesses?” “Tell me about your best work experience.” “Can you give me an example how you have worked with others to solve a problem?” Decide in advance what information and skills are pertinent to the position and reveal your strengths. For example, you could say, “While I was at school, I learned to get along with a diverse group of people.”
- Learn about the company. Be prepared; research the company or medical facility. What is the type of specialty? How many physicians are there?
- Dress appropriately. Because much communication is nonverbal, dressing appropriately for the interview is important. In most situations, you will be safe if you wear clean, pressed, conservative business clothes in neutral colors. Do not wear current fashions or fad clothing to an interview. Pay special attention to grooming. Keep makeup light, and wear little jewelry. Make sure that your hair and nails are clean and styled conservatively. Do not carry a large purse, backpack, books, coat, or hat. Leave extra clothing in an outside office and simply carry a pen, your portfolio with extra copies of your résumé, and a small pad for taking notes. Turn cell phones and pagers off during the interview or leave them in your vehicle.

- Be punctual. A good first impression is important and can be lasting. If you arrive late for the interview, a prospective employer may conclude that you will be late in arriving to work. Make certain you know the location and the time of the interview. Allow time for traffic, parking, and other preliminaries.
- Be professional. Being too familiar in your manner can be a barrier to a professional interview. Never call anyone by his or her first name unless you are asked to.
- Know the interviewer's title and the pronunciation of his or her name. Do not sit down until the interviewer does.
- Exhibit appropriate interview behavior. Always greet the interviewer with a smile. The interview is an opportunity to sell yourself to the employer. Offer your hand for a firm, confident handshake and be alert to the interviewer's body language. The flow of conversation during an interview should be natural. Maintain eye contact, pay attention to the interviewer, and show interest. Ask intelligent questions that you prepared before the interview. Remember, the interview is an opportunity for both the prospective employer and the prospective employee to gather information and make a good impression. In addition to reviewing the experience listed on your résumé, the interviewer will evaluate your personality and behavior. At the same time, you will be observing the office and learning more about the position. Try to be aware of the office's atmosphere, its equipment and supplies, and the attitudes of the staff. Does it seem like a pleasant, professional place to work? Request a tour of the facility and ask yourself if you would be happy in that work environment.
- Be poised and relaxed. Avoid nervous habits like tapping your pencil, playing with your hair, or covering your mouth with your hand. Watch language such as "you know," "ah," and "stuff like that." Use proper grammar and pronunciation as you talk with the interviewer—do not use slang. Do not smoke beforehand (you will smell like smoke), chew gum, fidget, or bite your nails.
- Maintain comfortable eye contact. Look the interviewer in the eye and speak with confidence. Your eyes reveal much about you; use them to show interest, confidence, poise, and sincerity. Use other nonverbal techniques like a firm handshake to reinforce your confidence.
- Relate your experience to the job. Use every question as an opportunity to show how your skills relate to the job. Use examples taken from school, previous jobs, your applied training, volunteer work, leadership in student organizations, and personal experience to indicate that you have the personal qualities, aptitude, and skills needed for this job.
- Be honest. While it is important to be confident and stress your strengths, it is equally important to your sense of integrity to be honest. Dishonesty always catches up to you sooner or later. Someone will verify your background, so do not exaggerate your accomplishments, grade point average, or experience.
- Focus on how you can benefit the company. Do not ask about benefits, salary, or vacations until you are offered the job. During a first interview, try to show how you can contribute to the organization. Do not appear to be too eager to move up through the company or suggest that you are more interested in gaining experience than in contributing to the company.
- Close the interview on a positive note. Thank the interviewer for his or her time, shake hands, and say that you are looking forward to hearing from him or her. On the way out of the office, thank the staff members involved in the interview. Ask for a business card from anyone to whom you think you might want to send a thank-you note. After leaving the interview, write down any additional information you want to remember. Every interview provides you with information about the medical assisting profession. Even if an interview does not result in a job, you will have met new people, developed a larger network of professional contacts, and gained valuable interviewing experience.
- Follow up with a letter within 2 days of the interview. After an interview, it is professional to send a thank-you letter to the person or persons from the company who conducted your interview. Your letter may be brief, but it should express your appreciation for the opportunity to have met with the interviewer, reaffirm your interest in the organization, and state your desire to remain a part of the selection process. By sending a thank-you letter, you display common business courtesy, which can make a difference in the employer's hiring decision. Even if you are not interested in continuing the interview and selection process, you should thank the employer for holding the interview.
- Complete an application. Some employers ask you to complete an employment application at an interview even when you provide a résumé. You can use your résumé to help you complete the application. Fill out the application neatly. Spell all words correctly and read and follow the instructions on the form carefully. Your application represents you; it must make a good first impression. Fill in all sections of the application—do not write "see résumé." Because an application is signed, it is a legal document and, as such, referring to your résumé, even though the information is there, is not allowed.
- Comply with other aspects of the application process. As part of the application process, employers are required by federal law to request documents that prove your identity and eligibility to work in the United States. To maintain the safety and confidentiality of the medical office, hospital, or laboratory, employers may also check your police record, credit rating, and history of chemical or alcohol abuse. A drug screen may be requested. You may be asked to provide the needed documents or to give the employer authorization to obtain them.
- Do not excessively contact the interviewer by telephone or e-mail after the interview. Prior to leaving the interview, it is acceptable to ask the interviewer when a decision will be made and if the interviewer will call to let you know whether an offer of employment will be made. It is acceptable to ask permission to contact the interviewer to follow up on the position.

Interview Questions

In order to prepare for your interview, you can anticipate that you may be asked any of the following questions:

- I see from your résumé that you graduated from ABC School. What did that school have to offer you that others did not?
- What is your 5-year goal?
- Tell me about yourself.
- What do you consider to be your greatest strengths and weaknesses?
- How would your instructors describe you?
- What qualifications do you have that make you a good candidate for this position?
- How could you make a contribution to this facility?
- How well do you work with others?
- What is your concept of a team environment?
- How well do you work under pressure?
- Will you be able to work overtime?
- Do you have the flexibility to work various shifts?
- What has been your major accomplishment to date?
- Why did you choose medical assisting as your career?
- Do you have any questions that you would like to ask?

It is also helpful to be prepared with any questions that you may have for the interviewer about the position or the facility. Remember, however, that questions about salary and benefits are not appropriate in a first interview.

An interviewer may ask you questions that you are not obligated to answer. These questions refer to age, race, sexual orientation, marital status, or number of children. Even if the questions sound harmless or the interviewer seems nonjudgmental, these questions have nothing to do with your skills or abilities. If the interviewer asks even one of these questions, you should reconsider whether you want to work for the organization.

If you are asked an inappropriate question during an interview, be polite and remain professional in declining to answer. You may simply state that you do not believe the requested information is necessary for the employer to evaluate your qualifications for the job. Try to move the discussion on to a more relevant topic.

Reasons for Not Being Hired

Employers in business were asked to list reasons for not hiring a job candidate. Some of the biggest complaints included

1. Poor appearance, not being dressed properly, and being poorly groomed.
2. Acting like a know-it-all.
3. Not communicating clearly, as well as poor voice, diction, and grammar.
4. Lack of planning for the interview, with no purpose or goals communicated.
5. Lack of confidence or poise.
6. No interest in or enthusiasm for the job.

7. Objectionable content on personal social networking pages.
8. Being interested only in the best salary offer.
9. Inappropriate voicemail greeting.
10. Unwillingness to begin in an entry-level position.
11. Making excuses about an unfavorable record.
12. No tact.
13. No maturity.
14. No curiosity about the job.
15. Being critical of past employers.

Salary Negotiations

Medical assisting salaries are varied and differ by geographic area. When you are a new graduate, you will begin your career as an entry-level medical assistant. As you gain experience, your compensation will reflect that. Salary ranges are determined by geographic location, medical specialty, years of experience, credentialing, and the job description.

The first step in determining your compensation needs is to know how much income is required to meet your living expenses. You will need to prepare a budget. Keep track of your overall expenditures and living expenses. Itemizing your basic living expenses can help you to prepare a budget.

Establishing a budget will give you an idea of the amount of income you may need. Once your budget is established, you have a negotiating benchmark. Employers will often ask you what you are looking for with regard to salary. If you answer directly, you may risk either quoting yourself out of a job or leaving money on the table. The best response to this question is to ask the employer the range of the position. Most positions have a low-to-high range. For example, the range for a specific position might be between \$23,000 and \$32,000 annually. Once you know the range, quote a little higher than what your budgetary amount is, which will give the employer room to negotiate down if necessary. Allow the employer to bring up salary first.

► On the Job

LO 58.5

Once you have a job, you must learn how to be an effective employee. There are many ways that your initiative enables the medical team in the office, hospital, clinic, or laboratory to function effectively. You must identify the important skills in your daily duties, stay competitive and marketable through continuing education, and integrate constructive criticism from your employee evaluations into your daily work and annual goals.

Job Description

During the initial paperwork process when you begin as a new employee, you may be asked to read and sign a job description for the position for which you have been hired. The purpose of a job description is to provide the standard benchmarks of your position. It will list and describe the position's expectations and the duties to be performed. A job description includes detailed information, such as

- Essential duties and responsibilities.
- Qualifications.

- Education and experience.
- Certificates, licenses, and registrations.
- Physical demands.
- Description of the work environment.

Employee Evaluations

Employee evaluations are usually held annually. An initial employment review generally occurs after a 90-day probationary period. Evaluations describe an employee's performance and, in most situations, the employee and the employer meet to discuss this. The purpose of an annual evaluation should be to check the goals and values of both the employer and the employee to make sure they support each other.

An employee evaluation form typically outlines the most important qualities and abilities needed for the job. It evaluates the employee's strengths and weaknesses. This form also may help determine whether an employee is worthy of a merit raise, which is a raise based on performance (as opposed to a cost-of-living raise). The quantity and quality of work are assessed on this form, as are initiative, judgment, and cooperation. A completed evaluation is placed in an official record of employment.

Continuing Education

After completing a medical assisting program, you should continue your education, setting specific educational

advancement goals on a yearly basis. For example, you may decide to obtain further education to learn more about the medical specialty in which you work. Once you obtain your certification as a medical assistant, you will be required to obtain a specific number of continuing education units (CEUs) yearly to maintain your certification credential.

As medical research expands its discoveries and as new technologies emerge, the necessity for self-education increases. You must read to stay abreast of updates in medicine. The need for more highly specialized training presents you with an opportunity for growth in your education and career. Medical publications are the best source for the latest medical information. Local and state medical assisting meetings also provide information about advances in the field. And, of course, the Internet is a valuable source for staying current about today's technological advances.

Self-education is an important skill for the medical assistant. It helps you to stay up-to-date in topics about medicine, healthcare, wellness, insurance products, and pharmaceuticals. Patients may ask questions about information they have read or about the effectiveness of certain new treatments and having this knowledge will enable you to better discuss this information and to refer patients' questions to their physician for more details.

PROCEDURE 58-1 Résumé Writing

Procedure Goal: To develop a résumé that defines your career objective and highlights your skills

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Paper, pen, dictionary, thesaurus, and computer

Method:

1. Type your full name, address (temporary and permanent, if you have both), telephone number with area code, and e-mail address (if you have one).
2. List your general career objective. You also may choose to summarize your skills. If you want to phrase your objective to fit a specific position, you should include that information in a cover letter to accompany the résumé.
3. List the highest level of education or the most recently obtained degree first. Include the school name, degree earned, and date of graduation. Be sure to list any special projects, courses, or participation in overseas study programs.
4. Summarize your work experience. List your most recent or most relevant employment first. Describe your responsibilities and list job titles, company names, and dates of employment. Summer employment, volunteer work, and student applied training also may be included. Use short sentences with strong action words such

as *directed, designed, developed, and organized*.

For example, condense a responsibility into "Handled insurance and billing" or "Drafted correspondence as requested."

RATIONALE: *Action verbs give the impression that you are an energetic and results-oriented employee.*

5. List any memberships and affiliations with professional organizations alphabetically or by order of importance.
6. Do not list references on your résumé.
RATIONALE: *It is easier to update your reference list if you maintain it in a separate file.*
7. Do not list the salary you wish to receive in a medical assisting position. Salary requirements should not be discussed until a job offer is received. If the ad you are answering requests that you include a required salary, it is best to state a range (no broader than \$5,000 from lowest to highest point in the range for an annual salary).
8. Print your résumé on an 8½ × 11-inch sheet of high-quality white or off-white bond paper. Carefully check your résumé for spelling, punctuation, and grammatical errors. Have someone else double-check your résumé if possible.
RATIONALE: *Your résumé is a printed reflection of you, so ensuring its accuracy and completeness is essential.*

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
58.1 Carry out professionalism in all applied training scenarios.	Students' weekly progress sheets should reveal new goals each week and progress on previous weeks' goals. Their assessment and the preceptor's assessments should be similar and show professionalism, willingness to learn, and continual progress throughout the applied training.
58.2 Summarize the steps necessary for obtaining professional certification.	When seeking national certification, students should determine if they are eligible to take the certification exam, gather necessary documents, apply for the exam, and study and prepare to take the exam.
58.3 Describe an appropriate strategy for finding a position.	Students should be able to list classified advertisements available in local papers, employment websites, networking, and employment agencies where employment assistance is available and should provide a workable, professional résumé that can be used to begin the employment search.
58.4 Explain key factors for a successful interview.	Students should be able to list key factors, such as portraying confidence, smiling, looking the interviewer in the eye, having questions ready for the interviewer about the position, and practicing answers to common interviewing questions. If possible, participation in a mock interview should be considered.
58.5 Describe ways of becoming a successful employee.	The keys to becoming a successful employee include using the job description to provide benchmarks for performance standards, using employee evaluations to improve performance, and continuing self-education throughout your career.

Recall Reagan from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. What should be Reagan's first steps in seeking employment?
2. What style of résumé should she choose?

3. What advantages might Reagan have if she applies for a position at the practice where she is finishing her applied training?
4. You are Reagan's instructor; she tells you that she is only going to apply for the position at the office where she is completing her applied training. What should you tell her?

EXAM PREPARATION QUESTIONS

- (LO 58.1) The document that states the expectations of the facility and student for the applied training site is a(n)
 - Time sheet
 - Affiliation agreement
 - Progress report
 - Applied training plan
 - Job description
- (LO 58.1) Feedback given in order to improve performance is
 - Affiliation
 - Benchmarking
 - Training agreement
 - Constructive criticism
 - Negotiation
- (LO 58.1) Which of the following personality types are generally the best for medical assisting students involved in applied training?
 - Quiet/passive
 - Aggressive/know-it-all
 - Assertive/confident
 - Shy/timid
 - Tentative/unbending
- (LO 58.3) Which résumé style generally works best for new medical assisting graduates seeking employment?
 - Targeted résumé
 - Chronological résumé
 - Functional résumé
 - Curriculum vitae
 - Simple résumé
- (LO 58.3) A reference is a recommendation for a position. Which of the following persons might you consider asking for a reference?
 - Former supervisor
 - Applied training supervisor/preceptor
 - Medical assisting instructor
 - Applied training coordinator
 - All of these
- (LO 58.1) If you are unable to attend your applied training due to an emergency, you should
 - Call your instructor and ask that he or she call the applied training site
 - Call the applied training site and the school 2 hours before you are to arrive
 - E-mail the applied training site that you will not be in
 - E-mail your instructor that you will be absent
 - Call the applied training site when it opens
- (LO 58.5) Employee evaluations are usually held
 - Each month
 - Yearly
 - Every 90 days
 - At the employee's request
 - Only if there is an issue with an employee
- (LO 58.2) Which of the following is a certification eligibility requirement of the AAMA?
 - Graduation from a CAAHEP- or ABHES-accredited school
 - US Armed Forces medical services training
 - Working as a medical assistant for 5 years
 - Teaching in a medical assisting program
 - Attending a medical assisting program that has 720 hours of training
- (LO 58.3) A chronological résumé is used most often when
 - A person has gaps in his or her work history
 - Someone has job experience
 - A person is changing jobs
 - A person is looking for a specific job
 - A person has just graduated
- (LO 58.3) A collection of documents you can take to a job interview is a(n)
 - Affiliation
 - Application
 - Portfolio
 - Reference
 - Résumé

SOFT SKILLS SUCCESS

Recall Reagan Patrick from the case study at the beginning of the chapter. You are working with Reagan Patrick today in the administrative area of the office. Your duties include checking patients out after seeing the healthcare practitioner and calling to schedule any outside appointments they need. Reagan has been checking patients out with your assistance all day and is doing an excellent job. When Mrs. Lemmonds checks out, you see that she has a note on her encounter form that she needs to be scheduled for bone densitometry. You ask Reagan to perform this duty and notice that Reagan is slightly

hesitant. How can you help Reagan maintain a professional demeanor even though she is unsure of her ability to schedule the appointment for Mrs. Lemmonds?

Prefixes, Suffixes, and Word Roots in Commonly Used Medical Terms

APPENDIX

NOTE: When referencing this appendix, note that some word parts are used in more than one way. For example, “cyt” serves as a word root in “cytology” but as a suffix in “astrocyte.” If you do not initially find the word part you are looking for, check the other sections of this appendix to see if it is listed as another type of word part.

Prefixes

a-, an- without, not
ab- from, away
acr-, acro- extremity, topmost
ad- to, toward
ambi-, amph-, amphi- both, on both sides, around
ante- before
antero- in front of
anti- against, opposing
aque- water
astro- star-like
auto- self
bi- twice, double
brachy- short
brady- slow
carboxy- containing carbon and oxygen or a carboxyl group
cata- down, lower, under
centi- hundred
cephal- head
chol-, chole-, cholo- gall

abdomino- abdomen
adeno- gland, glandular
adipo- fat
adreno- adrenal glands
aero- air
andr-, andro- man, male
ambly- dull, dim
angio- blood vessel
ano- anus
anthrac-, anthraco- coal, carbon
arterio- artery
arthro- joint
athero- soft, fatty deposit
atrio- pertaining to the atria of the heart
audi- hearing
baro- weight, pressure
bili- bile
bio- life
blasto-, blast- developing stage, bud, immature
bracheo- arm
broncho- bronchial (windpipe)
burs- bursa
carcino- cancer

cardio- heart
caud- tail
cellul- cells
cephalo- head
cerebr-, cerebro- brain
cervico- neck
chondro- cartilage
chromo- color
colo- colon
colp-, colpo- vagina
conjunctiv- conjunctiva
coro- body
cortico- cortex
cost-, costo- rib
cox- hip
crani-, cranio- skull
cuspid- projection
cysto- bladder, bag
cyto- cell, cellular
dacry-, dacryo- tears, lacrimal apparatus
dactyl-, dactylo- finger, toe
dent-, denti-, dento- teeth
derma-, dermat-, dermat- skin
dist- farthest from the point of attachment
diverticul- diverticula
dorsi-, dorso- back
dur-, dura- pertaining to the dura mater of the brain
encephalo- brain
entero- intestine
episi-, episio- pertaining to the pubic region
esophag- esophagus
esthesio- sensation
femor- femur
fibro- connective tissue
follicul- follicle
front- forehead
galact-, galacto- milk
gastr-, gastro- stomach
gingiv- gums
glomerulo- glomerulus
glosso- tongue
gluco-, glyco- sugar, sweet
granulo- granules
gravid- pregnant female
haemo-, hemato-, hem-, hemo- blood
hepa-, hepar-, hepato- liver
herni- rupture
hidro- sweat (perspiration)
histo- tissue
hydra-, hydro- water
hyster-, hystero- uterus
ictero- jaundice
ileo- ileum
immuno- pertaining to the immune system
interstit- interstices
karyo- nucleus, nut
kera-, kerato- horn, hardness, cornea
keratino- keratin
labyrinth- pertaining to the labyrinth of the ears

lacrim-, lacrimo- tears
lact-, lactifer- milk
laparo- abdomen
laryngo- pertaining to the larynx
later-, latero- side
linguo- tongue
lipo- fat
lith- stone
lobo- lobe
lun-, luna- moon
lymph-, lympho- lymphatic, spring water
mast-, masto- breast
med-, medi- middle
mening- meninges (covers the brain)
metacarpo- pertaining to the metacarpal bones
metatarso- pertaining to the metatarsal bones
metro-, metra- uterus
my-, myo- muscle
myel-, myelo- marrow
narco- sleep
nas-, naso- nose
nat-, nato- born
natri- sodium
necro- dead
nephr-, nephro- kidney
neu-, neuro- nerve
niter-, nitro- nitrogen
nucleo- nucleus
oculo- eye
odont- tooth
omphalo- navel, umbilicus
onco- tumor
onych-, onycho- pertaining to the nail of a finger or toe
oo- ovum, egg
oophor- ovary
ophthalmo- eye
opt-, opto- vision
or-, oro- pertaining to the mouth

orchid- testicle
os- mouth, opening
oste-, osteo- bone
oto- ear
ov-, ovi-, ovo- pertaining to an ovum or egg
paedo-, pedo- child
palpebro- eyelid
pancrea- pancreas
path-, patho- disease, suffering
pedicul- lice
pepso- digestion
peptid- pertaining to a peptide
phag-, phago- eating, consuming, swallowing
phalang- pertaining to the phalanges
pharyng-, pharyngo- throat, pharynx
phlebo- vein
photo- pertaining to light
pleuro- side, rib
pneumo- air, lungs
pod- foot
procto- rectum
proxim- close to the point of attachment
psych- the mind
pulmon-, pulmono- lung
pyelo- pelvis (renal)
pylor- pylorus (part of the stomach)
pyo-, pus- pus
pyro- fever, heat
refract- refraction, refractive
reni-, reno- kidney
retino- retina
rhabdo- rod-shaped
rhino- nose
sacchar- sugar
sacro- sacrum
sagitt- dividing into left and right
salpingo- tube, fallopian tube
sarco- flesh
sclero- hard, sclera

scolio- lateral curvature
sebace- oil
sensori- the senses
septi-, septic-, septic- poison, infection
sigmo- S-shaped
som-, soma- body
sperma-, spermato- semen, spermatozoa
spleno- spleen
steroid- steroid (lipid-soluble substance)
stomato- mouth
synapt- pertaining to a synapse
synov- synovium
sudorifer- sweat
superfic- near the surface
superi- above
tempor- pertaining to the temple
teno-, tenoto-, tendon- tendon
thermo- heat
thio- sulfa
thoraco- chest
thrombo- blood clot
thymo- thymus
thyro- thyroid gland
tricho- hair
tubulo- tube, tubule
tympan- eardrum
ureth- urethra
urino-, uro- urine, urinary organs
utero- uterus, uterine
uvulo- uvula
vagin- vagina
vaso-, vasculo- vessel
ventr- front
ventricul-, ventriculo- pertaining to the ventricles of the heart
ventri-, ventro- abdomen
vesico- blister
vulvo- pertaining to the vulva

Diseases and Disorders

Infectious Diseases Caused by Bacteria	
NAME	DESCRIPTION
Boil	Localized skin infection usually caused by staphylococcus bacteria.
Botulism	Type of food poisoning caused by a toxin produced by the bacterium <i>Clostridium botulinum</i> .
Chlamydia	Sexually transmitted infection caused by the bacterium <i>Chlamydia trachomatis</i> .
Conjunctivitis	Commonly called pink eye, this condition is highly contagious when the cause is bacterial. Can also be caused by viruses and allergies.
Gonorrhea	Highly contagious condition transmitted by sexual intercourse and caused by gonococcus bacteria.
<i>Haemophilus influenzae</i> serotype b (Hib) disease	Transferred by respiratory droplets. Can cause difficulty breathing through either epiglottitis and a sore throat or pneumonia with a fever.
Impetigo	A <i>Staphylococcus</i> or <i>Streptococcus</i> infection commonly found in children that causes lesions on the face or lower leg. Impetigo is highly contagious when contact is made with the lesions. This condition is treated with antibiotics.
Legionnaire's disease	Acute type of bacterial pneumonia caused by <i>Legionnaire</i> bacillus, a gram-negative organism. It grows in standing water such as that found in commercial air conditioners, humidifiers, water heaters, and evaporative condensers.
Lyme disease	Arthropod-borne disease caused by the spirochete <i>Borrelia burgdorferi</i> . The disease is transmitted by deer ticks. The signs and symptoms include skin lesions, central nervous system and cardiac involvement, and arthritis.
Meningitis	Inflammation of the meninges. Causes include bacterial, viral, and fungal infections.
Methicillin-resistant <i>Staphylococcus aureus</i>	Infection that causes red, swollen, painful pustules and is not responsive to methicillin and similar antibiotics.
Peptic ulcer	Gastrointestinal infection that causes gnawing or burning stomach pain; caused by the bacterium <i>Helicobacter pylori</i> .
Pertussis	Also called whooping cough. Caused by bacillus bacteria.
Pneumonia	Respiratory condition in which lung tissue is inflamed, usually causing difficulty breathing and a cough. Can also be caused by fungus or chemicals.
Rheumatic fever	Febrile (characterized by fever) disease, usually occurring after a streptococcal infection.
Strep throat	Inflammation and infection of the throat caused by streptococcus bacteria.
Syphilis	Infectious venereal disease, usually transmitted by sexual contact. Caused by a spirochete bacterium.
Tetanus	Infectious disease produced by the toxins from the tetanus bacillus. The first sign is stiffness of the jaw, hence the common name "lockjaw."
Tuberculosis (TB)	Disease that primarily affects the lungs but can spread to other parts of the body. Caused by various strains of the bacterium <i>Mycobacterium tuberculosis</i> .

Infectious Diseases Caused by Fungi	
NAME	DESCRIPTION
Tinea (ringworm)	Fungal skin infection that gets its name because it appears serpentine like a worm. <i>Tinea corporis</i> means the location is on the trunk or body, <i>tinea capitis</i> affects the scalp, and <i>tinea pedis</i> refers to the feet and is commonly known as athlete's foot.
Candidiasis	Commonly called a "yeast infection," this disease can be caused by one of several bacteria in the Candida family but is most commonly caused by <i>Candida albicans</i> . It may be oropharyngeal (thrush), vaginal, or invasive.
Pneumocystis pneumonia (PCP)	Infection that causes fever, dry cough, shortness of breath, and fatigue. Caused by <i>Pneumocystis jirovecii</i> .

Infectious Diseases Caused by Parasites and Protozoans	
NAME	DESCRIPTION
Amebic dysentery	Condition characterized by loose stools; causes inflammation of the intestines.
Giardiasis	Disease transmitted by the oral-fecal route and through untreated water. Causes diarrhea.
Lice	Can affect the head or the pubic area. Transmitted by contact with personal items used by someone who is infected. Lice and their eggs cause itching in the affected area.
Malaria	Disease transmitted to humans from the bite of an infected anopheles mosquito. Protozoan parasites invade the red blood cells and create symptoms such as high fever and chills.
Pinworm	Transmitted by oral-fecal route. This disease is common in children and causes anal itching and nighttime restlessness from eggs that are deposited around the anus.
Scabies	A highly contagious skin condition that results from a mite that burrows beneath the skin, leaving its feces behind. The feces leave red lines of inflammation on the skin.
Trichomoniasis	Condition that affects the reproductive organs and can be transmitted through sexual intercourse.

Infectious Diseases Caused by Viruses	
NAME	DESCRIPTION
Acquired immune deficiency syndrome (AIDS)	Syndrome caused by HIV (human immunodeficiency virus), resulting in decreased resistance to infections. Transmitted by blood and body fluids.
Chickenpox	Highly contagious disease caused by the varicella-zoster virus. Also called varicella, it is characterized by the presence of skin lesions. Shingles is also caused by varicella and is seen in patients who have previously had chickenpox.
Hepatitis	Hepatitis types A, B, C, D, and E are all caused by a virus. This disease affects the liver and can cause mild to moderate symptoms or chronic illness, and possibly death. Healthcare workers are encouraged to be vaccinated for hepatitis B because they are at risk for contact with client blood and body fluids.
Herpes simplex virus types 1 and 2 (HSV-1, HSV-2)	Typically, HSV-1 causes cold sores, is very contagious, and is spread through contact with infected saliva. HSV-2, known as genital herpes, is sexually transmitted. However, it should be noted that there can be crossing over, with HSV-1 infecting the genitals and HSV-2 infecting the mouth.
Human immunodeficiency virus (HIV)	Virus that destroys the immune system and can result in AIDS (acquired immune deficiency syndrome).
Human papillomavirus (HPV)	The most common sexually transmitted infection. Some strains of HPV cause harmless verrucae (warts); other strains are the greatest single risk factor for cervical cancer and may cause other, less common cancers such as cancer of the vagina, penis, and oropharynx.
Influenza	Commonly called "the flu"; an infection of both the upper and lower respiratory tracts.
Mononucleosis	Highly contagious viral infection spread through the saliva of the infected person. Caused by either the Epstein-Barr virus or the cytomegalovirus (CMV).

Infectious Diseases Caused by Viruses (<i>concluded</i>)	
NAME	DESCRIPTION
Norovirus	Most common cause of foodborne illness in the United States. Causes diarrhea, nausea, stomach pain, vomiting, fever, headache, and body aches.
Respiratory syncytial virus (RSV)	Infection that causes cough, sneezing, runny nose, fever, loss of appetite, wheezing, and dyspnea.
Severe acute respiratory syndrome (SARS)	Highly contagious disease that causes severe flu-like symptoms.
Upper respiratory (tract) infection (URI)	The common cold, including pharyngitis (sore throat). Caused by the rhinovirus.

Genetic Diseases	
DISEASE	DESCRIPTION
Albinism	Genetic condition in which a person is born with little or no pigmentation in the skin, eyes, or hair.
Cystic fibrosis	Life-threatening disease that affects the lungs and pancreas. It is one of the most common inherited life-threatening disorders among Caucasians in the United States.
Down syndrome	Abnormal cell division involving chromosome 21 that results in physical abnormalities and some form of mental disability. It is the single most common type of birth defect.
Fragile X syndrome	Most common inherited cause of learning disability, caused by a defect on one of the genes on the X chromosome. It affects boys more severely than girls.
Hemophilia	Inheritable bleeding disorder in which an essential clotting factor is low or missing, primarily affecting males.
Klinefelter's syndrome	Disorder in which males have an extra X chromosome, resulting in tall stature, pear-shaped fat distribution, small testes, sparse body hair, infertility, and slightly lower intelligence.
Muscular dystrophy	Group of genetic disorders that affect the muscular and nervous systems, most often affecting males.
Phenylketonuria (PKU)	Genetic disorder in which the body is unable to properly eliminate phenylalanine, which is an essential amino acid. Organ damage, mental disability, and even death are possible.
Turner's syndrome	Disorder that results when females have a single X chromosome. Symptoms include a webbed neck, broad chest, short stature, and infertility. Intelligence is normal.

Common Diseases and Disorders in the United States*		
DISEASE	EXAMPLES	SCREENING AND PREVENTION
Heart disease	Coronary artery disease, atherosclerosis, congestive heart failure	Monitor blood pressure and cholesterol and triglyceride levels, and have routine electrocardiograms (ECG).
Cancer	Skin, lung, breast, prostate, blood, colorectal, gynecologic, HPV-related	Have routine breast or prostate exam, Pap smear, and colonoscopy. Monitor size and shape of skin lesions. Maintain healthy eating habits and a good body weight, exercise, do not use tobacco products, and limit alcohol consumption.
Chronic lower respiratory diseases	Asthma, COPD, bronchitis	Do not use tobacco products, avoid irritants and allergens, and monitor air quality. Have routine screening tests (TB skin test) and vaccinations.
Cerebrovascular diseases	Stroke, deep vein thrombosis, aneurysm, embolism	Maintain healthy eating habits and a good body weight, exercise, do not use tobacco products, and limit alcohol consumption. Have routine screening tests and physical exams.

*Entries ordered from most to least common.

Common Diseases and Disorders in the United States* (*concluded*)

DISEASE	EXAMPLES	SCREENING AND PREVENTION
Alzheimer's disease		Maintain a healthy lifestyle and have a regular physical examination.
Diabetes mellitus	Type 1, Type 2, gestational	Have blood glucose tests, including fasting blood sugar, and hemoglobin A1c blood test. Maintain healthy eating habits and a good body weight, exercise, and limit alcohol and sugar consumption.
Influenza, pneumonia		Maintain a healthy lifestyle and obtain yearly flu and pneumonia vaccinations.
Nephritis/nephrosis	Chronic renal disease (CRD), end-stage renal disease (ESRD)	Have routine urinalysis. Maintain healthy eating habits and a good body weight, exercise, do not use tobacco products, and limit alcohol consumption.

*Entries ordered from most to least common.

Skin Lesions

NAME AND EXAMPLE	DESCRIPTION
Bulla 	A large blister or cluster of blisters.
Cherry angioma 	A common, noncancerous skin growth made up of blood.
Crust 	Dried blood or pus on the skin.
Ecchymosis 	A black-and-blue mark, or bruise.
Erosion 	A shallow area of skin worn away by friction or pressure.

Skin Lesions (*continued*)

NAME AND EXAMPLE	DESCRIPTION
Excoriation 	A scratch; may be covered with dried blood.
Fissure 	A crack in the skin's surface.
Keloid 	An overgrowth of scar tissue.
Macule 	A flat skin discoloration, such as a freckle or a flat mole.
Nodule 	A large pimple or small node (larger than 1 cm).
Papule 	An elevated mass similar to but smaller than a nodule.
Patch color 	A spot on the skin that is lighter or darker than regular skin.
Petechiae 	Pinpoint skin hemorrhages that result from bleeding disorders.

Skin Lesions (concluded)

NAME AND EXAMPLE	DESCRIPTION
Plaque 	A small, flat, scaly area of the skin.
Purpura 	Purple-red bruises; usually the result of clotting abnormalities.
Pustule 	An elevated (infected) lesion containing pus.
Scale 	A thin plaque of epithelial tissue on the skin's surface.
Telangiectasia 	Widely open (dilated) blood vessels in the outer layer of the skin.
Tumor 	A swelling of abnormal tissue growth.
Ulcer 	A wound that results from tissue loss.
Vesicle 	A blister.
Wheal 	A hive.

Classifications of Fractures

NAME AND EXAMPLE	DESCRIPTION
 Closed fracture (simple fracture)	Fracture in which the skin remains intact.
 Comminuted fracture	Fracture in which the bone has broken into several fragments.
 Complete fracture	Fracture that goes across the entire bone.

Classifications of Fractures (*continued*)

NAME AND EXAMPLE	DESCRIPTION
 Greenstick fracture	Fracture commonly seen in children; occurs in bones that are not completely ossified, so there is a bending and only one side of the bone is fractured, rather than a complete breaking of bone.
 Impacted fracture	Fracture in which one end of the fractured bone is driven into the interior of the other.
 Incomplete fracture	Fracture that goes through only part of the bone.

Classifications of Fractures (*concluded*)

NAME AND EXAMPLE	DESCRIPTION
 Open fracture (compound fracture)	Fracture in which the skin is broken.

Bone Disorders

NAME	DESCRIPTION
Bursitis	Inflammation of a bursa, which is the fluid-filled sac that cushions tendons. (Tendons attach muscles to bone.)
Carpal tunnel syndrome (CTS)	Occurs when the median nerve in the wrist is excessively compressed by an inflamed tendon (the flexor retinaculum).
Fractures	Cracks, breaks, or splintering of a bone.
Gout (gouty arthritis)	A type of arthritis associated with high uric acid levels in the blood with crystalline deposits in the joints, kidneys, and various soft tissues.
Kyphosis	An abnormal, exaggerated curvature of the spine, most often at the thoracic level. This condition is often referred to as humpback.
Lordosis	An exaggerated inward (convex) curvature of the lumbar spine. The condition is sometimes called swayback.
Osteoarthritis (OA)	Also known as degenerative joint disease (DJD) or wear-and-tear arthritis.
Osteogenesis imperfecta (brittle bone disease)	People with brittle bone disease have decreased amounts of collagen in their bones, which leads to very fragile bones.
Osteoporosis	A condition in which bones become thin (more porous) over time.
Osteosarcoma	A type of bone cancer that originates from osteoblasts, the cells that make bone tissue. It is most often seen in children, teens, and young adults and occurs more often in males than females.
Paget's disease	Causes bones to enlarge and become deformed and weak. It usually affects people older than 40 years of age.
Rheumatoid arthritis (RA)	A chronic, systemic inflammatory disease that attacks the smaller joints such as those in the hands and feet.
Scoliosis	An abnormal, S-shaped lateral curvature of the thoracic or lumbar spine.

Classifications of Burns

NAME	DESCRIPTION
 © Sheila Terry/Science Source	First-degree A superficial burn that causes pain and makes the surrounding skin turn red.
 © Dr. P. Marazzi/Science Source	Second-degree A partial-thickness burn that extends deeper into the skin than first-degree burns; causes blistering along with pain and redness.
 © John Radcliffe Hospital/Science Source	Third-degree A full-thickness burn that involves all layers of the skin and requires immediate medical assistance.

Diseases and Disorders of the Integumentary System

NAME	DESCRIPTION
Acne vulgaris	An inflammatory condition of the skin follicles and sebaceous glands.
Alopecia	The absence or loss of hair, especially of the head (baldness).
Basal cell carcinoma	Skin cancer that originates from the basal layer of the epidermis and rarely metastasizes (spreads).
Cellulitis	An inflammation of the connective tissue in skin that is most often seen on the face and legs. A bacterial infection by <i>Staphylococcus aureus</i> or <i>Streptococcus</i> is the most common cause.
Comedos	Commonly known as blackheads; collections of bacteria, dead epithelial cells, and dried sebum.
Dermatitis	A general term describing any inflammation of the skin; can be caused by a wide range of disorders.
Eczema	A common chronic dermatitis that often has acute phases or flareups followed by periods of remission. The rash of eczema can appear anywhere on the body and appears as a red, scaly, pruritic (itchy) rash that may be painful.

Diseases and Disorders of the Integumentary System *(concluded)*

NAME	DESCRIPTION
Folliculitis	Inflammation of hair follicles. When it involves a single hair follicle, the condition is called a furuncle. When more than one hair follicle is involved, it is a carbuncle.
Herpes simplex types 1 and 2	Type 1 causes cold sores and is very contagious. Type 2, which is genital herpes, is sexually transmitted.
Jaundice	A yellow cast to the skin that often occurs with liver disease.
Lentigos	Commonly called liver spots or age spots; these are not caused by the liver but are the result of excessive melanin production due to overexposure to sunlight (UV rays).
Malignant melanoma	Skin cancer that arises from melanocytes and often metastasizes (spreads).
Psoriasis	A common chronic inflammatory skin condition that has an autoimmune basis.
Rosacea	A skin disorder that commonly appears as facial redness, predominantly over the cheeks and nose.
Squamous cell carcinoma	Skin cancer that arises from the upper cells of the epidermis and often metastasizes (spreads).

Diseases and Disorders of the Muscular System

NAME	DESCRIPTION
Fibromyalgia	A fairly common condition that results in chronic pain primarily in joints, muscles, and tendons. It most commonly affects women between the ages of 20 and 50.
Muscular dystrophy (MD)	A group of inherited disorders characterized by muscle weakness and a loss of muscle tissue.
Myasthenia gravis	A condition in which affected persons experience muscle weakness. In this autoimmune condition, a person produces antibodies that prevent muscles from receiving neurotransmitters from neurons.
Sprains	Injuries that excessively stretch or tear ligaments at a joint.
Strains	Caused by stretching or tearing of muscles or tendons.
Tendonitis	Painful inflammation of a tendon as well as of the tendon–muscle attachment to a bone.
Tetanus	A condition caused by a toxin produced by the bacterium <i>Clostridium tetani</i> . It has a high mortality rate but is completely preventable through regular vaccinations.
Torticollis	Also known as wry neck. This condition is due to abnormally contracted neck muscles. The head typically bends toward the side of the contracted muscle and the chin rotates to the opposite side.

Diseases and Disorders of the Blood and Circulatory System

NAME	DESCRIPTION
Anemia	A symptom of an underlying disease process. Anemia occurs when the blood has less than its normal oxygen-carrying capacity. Anemia is the most common blood disorder in the United States and occurs more often in women than in men.
Aneurysm	A ballooned, weakened arterial wall. The most common locations of aneurysms are the aorta and the arteries in the brain, legs, intestines, and spleen. An aortic aneurysm is a bulge in the wall of the aorta.
Leukemia	A neoplastic condition in which the bone marrow produces a large number of WBCs that are not normal.
Thrombocythemia	A condition in which there is an increase in the platelet count. This condition is the opposite of thrombocytopenia.
Thrombocytopenia	A condition in which there are too few platelets, causing abnormal bleeding. This can be caused by a variety of situations, such as leukemia, certain medications, or idiopathic (unknown) reasons. The bleeding may be mild or life threatening.
Thrombophlebitis	A condition in which a thrombus and inflammation develop in a vein. It most commonly occurs in the deeper veins of the legs.
Varicose veins (varices or varicosities)	Tortuous or twisted, dilated veins that are usually seen in the legs. They affect women more often than men.

Diseases and Disorders of the Cardiovascular System	
NAME	DESCRIPTION
Congenital heart disease	A problem with the heart's structure and function due to abnormal heart development before birth.
Congestive heart failure (CHF)	Failure of the heart to pump effectively. The heart weakens over time and loses its ability to supply blood to the body.
Coronary artery disease (CAD), atherosclerosis	A condition involving partial or complete blockage of major coronary arteries that supply blood to the heart.
Dysrhythmias	Also known as arrhythmias; abnormal heart rhythms and/or rates.
Endocarditis	An inflammation of the innermost lining of the heart and heart valves, usually caused by bacterial infections.
Murmurs	Abnormal heart sounds. Not all murmurs indicate a heart disorder. Murmurs are graded from 1 to 6, with 6 being quite loud and the most serious.
Myocardial infarction (MI, heart attack)	Death of heart tissue due to deprivation of oxygen. The cardiac muscle sustains damage because of ischemia.
Myocarditis	An inflammation of the muscular layer of the heart caused by a viral infection. It leads to weakening of the heart wall.
Pericarditis	An inflammation of the pericardium, usually caused by complications of viral or bacterial infections, MIs, or chest injuries.

Diseases and Disorders of the Lymphatic and Immune Systems	
NAME	DESCRIPTION
Allergies	Excessive immune responses to stimuli that would not ordinarily cause a reaction.
Autoimmune disease	A disease in which the immune system targets itself.
Chronic fatigue syndrome (CFS)	Causes a person to feel severe tiredness; possibly caused by the Epstein-Barr virus (EBV).
HIV/AIDS	A viral disease spread through blood and body fluids. AIDS is caused by the human immunodeficiency virus (HIV). HIV attacks T lymphocytes.
Lymphadenitis	Inflammation of lymph nodes; can be viral or bacterial.
Lymphadenopathy	Any disease involving the lymph nodes; causes can be autoimmune disease or malignancy.
Lymphedema	Blockage of lymphatic vessels; can be caused by genetics, parasitic infections, trauma to the vessels, tumors, radiation therapy, cellulitis, and surgeries.
Systemic lupus erythematosus (SLE)	An autoimmune disorder that affects women more often than men. Affects many organ systems of the body and has numerous symptoms, usually including joint pain and swelling.

Diseases and Disorders of the Respiratory System	
NAME	DESCRIPTION
Allergic rhinitis	A hypersensitivity reaction to various airborne allergens.
Asthma	Hyperactivity of the bronchioles; an inflammatory response with excess mucus production.
Atelectasis	Commonly called collapsed lung; may occur after surgery or due to pleural effusion.
Bronchitis	Inflammation of the bronchi; can be acute or chronic. Often follows a cold. One common cause of chronic bronchitis is cigarette smoking.
Chronic obstructive pulmonary disease (COPD)	A group of lung disorders in which obstruction limits airflow to the lungs. COPD includes chronic bronchitis and emphysema.

Diseases and Disorders of the Respiratory System (*concluded*)

NAME	DESCRIPTION
Emphysema	A lung disease in which the alveolar walls are destroyed; often caused by cigarette smoking.
Laryngitis	An acute inflammation of the larynx; caused by viruses, bacteria, polyp formation, excessive use due to talking and singing, allergies, smoking, heartburn, alcohol use, nerve damage, or stroke.
Lung cancer	The leading cancer-related cause of death in the United States. Caused by smoking or exposure to radon, asbestos, and industrial carcinogens. The three types are small cell lung cancer, squamous cell lung cancer, and adenocarcinoma.
Mesothelioma	A type of cancer that affects the pleura and is a result of asbestos exposure.
Pleuritis or pleurisy	A condition in which the pleura become inflamed.
Pneumonia (pneumonitis)	An inflammation of the lungs caused by a bacterial, viral, or fungal infection.
Pneumoconiosis	Lung diseases that result from years of exposure to different environmental or occupational types of dust.
Pulmonary edema	A condition in which fluids fill the alveoli of the lungs, most commonly occurring with left heart failure.
Pulmonary embolism	A blocked artery in the lungs, usually caused by a blood clot.
Respiratory distress syndrome (RDS)	Kills apparently healthy infants; the cause is unknown.
Severe acute respiratory syndrome (SARS)	A viral disease that is highly contagious and sometimes fatal.
Sinusitis	An inflammation of the membranes lining the sinuses. It can be acute or chronic.
Sudden infant death syndrome (SIDS)	The sudden and unexpected death of an infant under 1 year of age. There is no explainable cause of death.

Diseases and Disorders of the Nervous System

NAME	DESCRIPTION
Alzheimer's disease	A progressive, degenerative disease of the gray matter of the brain that causes dementia.
Amyotrophic lateral sclerosis (ALS)	Commonly known as Lou Gehrig's disease; a fatal disorder characterized by the degeneration of neurons in the spinal cord and brain.
Bell's palsy	A disorder in which facial muscles are very weak or temporarily totally paralyzed. Results from damage to the facial nerve; causes are unknown.
Brain tumors and cancers	Abnormal growths in the brain. Malignant tumors that start in brain tissue are called primary brain cancers. Those that start elsewhere and metastasize to the brain are classified as secondary brain cancers.
Epilepsy	A condition in which the brain experiences repeated spontaneous seizures due to abnormal electrical activity of the brain.
Guillain-Barré syndrome	A disorder in which the body's immune system attacks part of the peripheral nervous system. It has a sudden and unexpected onset.
Headaches	Caused by a variety of factors. Include episodic tension headaches, chronic tension headaches, migraines, and cluster headaches.
Meningitis	An inflammation of the meninges.
Multiple sclerosis (MS)	A chronic disease of the central nervous system in which myelin is destroyed. Some known causes are viruses, genetic factors, and immune system abnormalities.

Diseases and Disorders of the Nervous System <i>(concluded)</i>	
NAME	DESCRIPTION
Neuralgia	A group of disorders commonly referred to as nerve pain; most frequently occur in the nerves of the face.
Parkinson's disease	A nervous system disorder that is slowly progressive and degenerative.
Sciatica	A condition in which the sciatic nerve is damaged, commonly due to excessive pressure on the nerve from prolonged sitting.
Stroke or cerebrovascular accident (CVA)	Occurs when brain cells die because of inadequate blood perfusion of the brain.

Diseases and Disorders of the Urinary System	
NAME	DESCRIPTION
Acute kidney (renal) failure (ARF)	A sudden loss of kidney function due to burns, dehydration, low blood pressure, hemorrhage, allergic reactions, obstructions, poisons, alcohol abuse, or trauma.
Chronic kidney (renal) failure (CRF)	A condition in which the kidneys slowly lose their ability to function due to diabetes, hypertension, kidney disease, or heart failure.
Cystitis	A urinary bladder infection caused by different types of bacteria.
Glomerulonephritis	An inflammation of the glomeruli of the kidney, caused by bacterial infections, renal diseases, and immune disorders.
Incontinence	A condition in which an adult cannot control urination. Can be temporary or long lasting; caused by various medications, UTIs, nervous system disorders, cancers, surgery, trauma, or pregnancy.
Polycystic kidney disease (PKD)	A disorder in which the kidneys enlarge because of the presence of many cysts within them. The cause is hereditary.
Pyelonephritis	A type of complicated UTI that begins as a bladder infection and spreads up one or both ureters into the kidneys.
Renal calculi (kidney stones)	Solid masses of crystals that obstruct the ducts within the kidneys or ureters. Painful condition caused by gouty arthritis, ureter defects, overly concentrated urine, or UTIs.

Diseases and Disorders of the Male Reproductive System	
NAME	DESCRIPTION
Benign prostatic hypertrophy (BPH)	The nonmalignant enlargement of the prostate gland.
Epididymitis	An inflammation of the epididymis. Most cases start as an infection of the urinary tract.
Impotence, or erectile dysfunction (ED)	A disorder in which a male cannot achieve or maintain an erection to complete sexual intercourse. Can be caused by many physical or psychological conditions.
Prostate cancer	One of the most common cancers in men older than 40. A high-fat diet, increased age, and genetic predisposition all increase the risk.
Prostatitis	An inflammation of the prostate gland; can be acute or chronic. May be caused by bacterial infections, catheterization, trauma, excessive alcohol consumption, or scarring.
Testicular cancer	A malignant growth in one or both testicles. Occurs more commonly in males 15 to 30 years of age and is very aggressive.

Diseases and Disorders of the Female Reproductive System

NAME	DESCRIPTION
Breast cancer	One of the most common cancers in females. Evaluated and graded based on tumor size and how far cells have traveled from the site of origin.
Cervical cancer	This type of cancer usually develops slowly, and with early detection by a yearly Pap smear, treatment is often successful.
Cervicitis	Inflammation of the cervix, caused by an infection.
Dysmenorrhea	Condition of experiencing severe menstrual cramps that limit normal daily activities.
Endometriosis	A condition in which tissues that make up the lining of the uterus grow outside the uterus.
Fibrocystic breast change	A common condition consisting of abnormal but usually benign cysts in the breasts that vary in size related to the menstrual cycle.
Fibroids	Benign tumors that grow in the uterine wall.
Infertility	The inability to conceive a child due to scarring of the fallopian tubes, STIs, PID, endometriosis, or hormone imbalance.
Ovarian cancer	Considered more deadly than the other types of gynecologic cancers because its symptoms are mild and indistinct.
Pelvic inflammatory disease (PID)	An acute or chronic infection of the reproductive tract caused by untreated STIs or bacteria.
Premenstrual syndrome (PMS)	A collection of symptoms that occur just before the menstrual period. Symptoms include anxiety, depression, irritability, bloating, and diarrhea.
Uterine (endometrial) cancer	Most common in postmenopausal women. It may be related to increased levels of estrogen.
Vaginitis	An inflammation of the vagina, associated with abnormal vaginal discharge.
Vulvovaginitis	An inflammation of the vulva and vagina.

Diseases and Disorders of the Digestive System

NAME	DESCRIPTION
Appendicitis	An inflammation of the appendix. If not treated promptly, it can be life threatening.
Cholelithiasis (gallstones)	Hardened deposits of bile that can form in the gallbladder. Two types of calculi are cholesterol and pigment stones.
Cirrhosis	A chronic liver disease in which normal liver tissue is replaced with nonfunctional scar tissue.
Colitis	An inflammation of the large intestine. This condition can be chronic or short-lived, depending on the cause.
Colorectal cancer	Usually arises from the lining of the rectum or colon. This type of cancer is curable if diagnosed and treated early. It is the third most common cause of death due to cancer in both men and women.
Constipation	The condition of difficult defecation or elimination of feces.
Crohn's disease	A type of inflammatory bowel disease. It can affect any region of the digestive tract from the mouth to the anus, but most often affects the ileum (lower part of the small intestine).
Diarrhea	The condition of watery and frequent feces. Many cases of diarrhea do not require treatment because they are usually self-limiting and stop within a day or two.
Diverticulitis	An inflammation of diverticuli in the intestine. Diverticuli are abnormal dilations or pouches in the intestinal wall. When the diverticuli are not inflamed, the condition is known as <i>diverticulosis</i> .
Gastric, or stomach, ulcers	Occur when the lining of the stomach breaks down.

Diseases and Disorders of the Digestive System (*concluded*)

NAME	DESCRIPTION
Gastritis	An inflammation of the stomach lining; often referred to as an upset stomach.
Gastroesophageal reflux disorder (GERD)	This occurs when stomach acids are pushed into the esophagus (also called heartburn). If not treated, GERD can cause erosion of the esophagus and even esophageal cancer.
<i>Helicobacter pylori</i> (<i>H. pylori</i>)	Organism implicated as being responsible for many diseases and disorders, including gastric ulcers.
Hemorrhoids	Varicosities (varicose veins) of the rectum or anus.
Hepatitis	An inflammation of the liver. There are many different types of hepatitis, but they all involve inflammation of the liver. Many signs and symptoms are shared, regardless of the cause of the inflammation.
Hiatal hernias	Occur when a portion of the stomach protrudes into the thoracic cavity through an opening (esophageal hiatus) in the diaphragm.
Inguinal hernias	Occur when a portion of the large intestine protrudes into the inguinal canal, which is located where the thigh and the body trunk meet. In males, the hernia can also protrude into the scrotum.
Oral cancer	Usually involves the lips or tongue but can occur anywhere in the mouth. This type of cancer tends to spread rapidly to other organs because of the high vascularity of this area.
Pancreatic cancer	The fourth leading cause of cancer death in the United States. The poor prognosis and 5-year survival rate of only 5% is due to the late diagnosis in many cases.
Stomach cancer	Most commonly occurs in the uppermost (cardiac) portion of the stomach. It appears to occur more frequently in Japan, Chile, and Iceland than in the United States. This may be due to diets high in nitrates that are known to be carcinogenic.
Stomach ulcer	A condition in which the lining of the stomach breaks down.

Diseases and Disorders of Metabolism and Nutrition

NAME	DESCRIPTION
Anorexia nervosa	An eating disorder in which individuals have a perception of being overweight regardless of their actual weight.
Bulimia nervosa	An eating disorder in which the person may be of normal weight and may eat normal or even excessive amounts of food but then vomits to rid himself or herself of the calories. Also called binge-and-purge eating.
Celiac disease	An immune reaction to eating gluten that causes the individual's body to attack the small intestinal mucosa. In a similar disorder, known as non-celiac gluten sensitivity, patients cannot tolerate gluten and have similar symptoms, with the addition of headache, joint pain, and numbness in the extremities.
Hypercholesterolemia	An excess of cholesterol in the blood.
Kwashiorkor	A type of starvation in which there is too little protein in the diet.
Malnutrition	Inadequate or excessive caloric intake.
Marasmus	A type of starvation that entails both protein and calorie insufficiency.
Metabolic syndrome	A group of symptoms such as hypertension, hyperinsulinism, excess body fat around the waist, and hypercholesterolemia. Lifestyle changes, medication, and regular appointments with a healthcare provider are essential.
Obesity	A body weight greater than 20% above the standard is considered obesity, and 50% over the standard is considered morbid obesity.
Starvation	A type of malnutrition resulting from inadequate caloric intake, inadequate resources, dietary imbalances, illness, or self-imposed starvation.

Diseases and Disorders of the Endocrine System

NAME	DESCRIPTION
Acromegaly	A condition caused by the secretion of too much growth hormone after puberty that causes the hands, feet, and face to take on unusual enlargement.
Addison's syndrome	Hyposecretion of ACTH in which patients experience anorexia, fatigue, weight loss, GI problems, and bronzing of the skin.
Diabetes insipidus	Hyposecretion of ADH. Symptoms include excessive urination, thirst, and dehydration.
Diabetes mellitus	Hyposecretion of insulin, categorized into Type 1 (insulin dependent) and Type 2 (non-insulin dependent).
Dwarfism (achondroplasia)	Abnormal underdevelopment of the body due to hyposecretion of growth hormone (GH). Adult height is 4 feet 10 inches or less.
Epinephrine and norepinephrine imbalances	Cause increase in blood pressure, tachycardia, and tachypnea.
Estrogen imbalances	Hyposecretion before or during menopause results in hot flashes, vaginal dryness, mood changes, depression, and loss of bone density.
Gigantism	An abnormal increase in the length of long bones due to hypersecretion of growth hormone during childhood.
Hypercalcemia	An increase in blood calcium levels, resulting in more calcium going into bone.
Hyperthyroidism	Excess secretion of thyroid hormone (TSH). Also called Grave's disease, it causes an overall increase in metabolism.
Hypocalcemia	A condition in which there is too little calcium in the blood.
Hypoglycemia	A low level of glucose in the blood.
Hypothyroidism	Too little TSH is secreted, resulting in slowing of metabolism.
Melatonin imbalances	Hyposecretion disturbs the sleep cycle and contributes to depression.
Pancreatic tumors	Malignant tumors have a poor prognosis due to difficulty in diagnosing.
Pheochromocytoma	A benign tumor of the adrenal medulla that can cause an increase in blood pressure.
Thymosin imbalances	Hyposecretion results in lack of mature T lymphocytes and a decrease in immunity.
Thyroid tumor	An abnormal growth on the thyroid gland. May be benign or malignant.

Diseases and Disorders of the Special Senses—the Eye

NAME	DESCRIPTION
Amblyopia	Commonly called lazy eye; occurs when a child does not use one eye regularly.
Astigmatism	Occurs when the cornea or lens has an abnormal shape, which causes blurred images in near or distant vision.
Blepharitis	An inflammation of the eyelid, as well as corneal abrasions (scratching of the cornea).
Cataracts	Opaque structures within the lens that prevent light from going through the lens. Over time, images begin to look fuzzy; if left untreated, cataracts may cause blindness.
Color blindness	The inability to see certain colors. May be inherited; occurs more commonly in males.
Dry eye syndrome (xerophthalmia)	One of the most common eye problems treated by physicians. This syndrome results from a decreased production of the oil within tears, which normally occurs with age.
Ectropion	Eversion of the lower eyelid.
Entropion	Inversion of the lower eyelid.

Diseases and Disorders of the Special Senses—the Eye (*concluded*)

NAME	DESCRIPTION
Glaucoma	Indicated by an increase in intraocular pressure, caused by a buildup of aqueous humor in the anterior chamber. If untreated, this excess pressure can lead to permanent damage of the optic nerve that can result in blindness.
Hyperopia	Farsightedness.
Macular degeneration	A progressive disease that usually affects people over the age of 50. It occurs when the retina no longer receives an adequate blood supply. It is the most common cause of vision loss in the United States.
Myopia	Nearsightedness.
Nystagmus	Rapid, involuntary eye movements. The movements may be horizontal or vertical.
Presbyopia	A common eye disorder that results in the loss of lens elasticity. It develops with age and causes a person to have difficulty seeing objects that are close up.
Retinal detachment	Occurs when the layers of the retina separate. It is considered a medical emergency and if not treated right away leads to permanent vision loss.
Strabismus	A misalignment of the eyes. Convergent strabismus is commonly referred to as crossed eyes.

Diseases and Disorders of the Special Senses—the Ear

NAME	DESCRIPTION
Cerumen impaction	A buildup of ear wax within the external auditory canal.
Menière's disease	A disturbance in the equilibrium characterized by <i>vertigo</i> (dizziness), ringing in the ears, nausea, and progressive hearing loss.
Otitis externa	An inflammation of the outer ear.
Otitis media	An inflammation of the middle ear.
Otosclerosis	The immobilization of the stapes within the middle ear; a common cause of conductive hearing loss.
Presbycusis	Hearing loss because of the aging process.
Tinnitus	Ringing in the ears.
Vertigo	Dizziness.

10× lens (ten lenz) A magnifying lens in the ocular of a microscope that magnifies an image ten times.

24-hour urine specimen (Twen't ē fūr ovr' yūr'in spes'i-mēn) A urine specimen collected over a 24-hour period and used to complete a quantitative and qualitative analysis of one or more substances, such as sodium, chloride, and calcium.

AAMA See **American Association of Medical Assistants.**

abandonment (ă-ban'dōn-mēnt) A situation in which a healthcare professional stops caring for a patient without arranging for care by an equally qualified substitute.

ABA number (nūm'bēr) A fraction appearing in the upper-right corner of all printed checks that identifies the geographic area and specific bank on which the check is drawn.

abduction (ab-dŭk'shŭn) Movement away from the body.

ABHES See **Accrediting Bureau of Health Education Schools.**

abscess (ab'ses) A collection of pus (white blood cells, bacteria, and dead skin cells) that forms as a result of infection.

absorption (ăb-sōrp'shŭn) The process by which one substance is absorbed, or taken in and incorporated, into another, as when the body converts food or drugs into a form it can use.

abuse (ă-byūs') A practice or behavior that is not indicative of or in line with sound medical or fiscal activity.

access (ak'ses) The way patients enter and exit a medical office.

accessibility (ak-ses'ă-bil'i-tē) The ease with which people can move into and out of a space.

accommodation (ă-kom'ō-dă'shŭn) The ability of the lens to change shape, allowing the eye to focus images of objects that are near or far away.

accounting (ă-kownt-ing) The process of communicating the income and expenses of a business and its financial health.

accounts payable (A/P) (ă-kownts' pā'ă-běl) Money owed by a business; the practice's expenses.

accounts receivable (A/R) (ă-kownts' rē-sē'vă-běl) Income or money owed to a business.

accreditation (ă-kred'i-tă'shŭn) The documentation of official authorization or approval of a program.

Accrediting Bureau of Health Education Schools (ABHES) (ă'kre-dăt-ing byoor-oh helth ed'yŭ-kă'shŭn skulz)

An accrediting body that accredits private postsecondary institutions and programs that prepare individuals for entry into the medical assisting profession.

acetabulum (as-ě-tab'yŭ-lŭm) The hip socket.

acetylcholine (as'ě-til-kō'lēn) A neurotransmitter released by the parasympathetic nerves onto organs and glands for resting and digesting.

acetylcholinesterase (as'ě-til-kō'lin-es'tēr-ās) An enzyme within the nervous system that hydrolyzes acetylcholine to acetate and choline.

acid-fast stain (as'id-fast stān) A staining procedure for identifying bacteria that have a waxy cell wall.

acids (as'idz) Electrolytes that release hydrogen ions in water.

acinar cells (as'i-năr selz) Cells in the pancreas that produce pancreatic juice.

acquired immunodeficiency syndrome (AIDS) (ă-kwīrd' im'yŭ-nō-dě-fish'ēn-sē sin'drōm) The most advanced stage of HIV infection; it severely weakens the body's immune system.

acromegaly (ak'rō-meg'ă-lē) A disorder in which too much growth hormone is produced in adults.

acrosome (ak'rō-sōm) An enzyme-filled sac covering the head of a sperm that aids in the penetration of the egg during fertilization.

ACTH See **adrenocorticotrophic hormone.**

action potential (ak'shŭn pō-ten'shăl) The flow of electrical current along the axon membrane.

active file (ăk'tiv fil) A file used on a consistent basis.

active listening (ak'tiv lis'ēn-ing) Part of two-way communication, such as offering feedback or asking questions; contrast with **passive listening.**

active transport (ak'-tiv trans'pōrt) The movement of a substance across a cell membrane from an area of low concentration to an area of high concentration.

acupressure (ak'yŭ-presh-ŭr) Pressure applied by hands to various areas of the body to restore balance in the body's energy flow.

acupuncture (ak'yŭ-pŭngk'shŭr) The practice of inserting needles into various areas of the body to restore balance in the body's energy flow.

acupuncturist (ak'yŭ-pŭngk'shŭr-ist) A practitioner of acupuncture. The acupuncturist uses hollow needles inserted into the patient's skin to treat pain, discomfort, or systemic imbalances.

acute (ă-kyŭt') Having a rapid onset and progress, as acute appendicitis.

ADA See **Americans with Disabilities Act.**

ADA Amendments Act of 2008 (ADAAA) (ă-mend'mēnts akt) A 2008 amendment to the ADA that broadens the definition of disability, making it easier for individuals who seek ADA protection to establish that they have a disability.

addiction (ă-dik'shŭn) A physical or psychological dependence on a substance, usually involving a pattern of behavior that includes obsessive or compulsive preoccupation with the substance and the security of its supply, as well as a high rate of relapse after withdrawal.

Addison's disease (ad'i-sōns di-zēz) A condition in which the adrenal glands fail to produce enough corticosteroids.

add-on code (ad'on' kōd) A code indicating procedures that are usually carried out in addition to another procedure. Add-on codes are used together with the primary code.

add-on safety features (ad'on săf'tē fē'chŭrz) Features on injection, phlebotomy, and winged steel needles that

provide protection from needlestick injury. They consist of a hinged or sliding sheath attached to the needle that can be activated with one hand, keeping the user's hands behind the needle.

adduction (ă-dŭk'shŭn) Movement toward the body.

adenoids (ad'ĕ-noydz) See **pharyngeal tonsils**.

ADH See **antidiuretic hormone**.

adjustment (ă-jŭst'mĕnt) Manual treatment given by a chiropractor that moves the joints of the spine and other joints into proper alignment. Also, an amount taken off a bill which is the difference between the fees charged for a service and the fees allowed by insurance. Also known as a write-off.

administer (ad-min'i-stir) To give a drug directly by injection, by mouth, or by any other route that introduces the drug into the body.

adrenocorticotrophic hormone (ACTH) (ă-drĕ'nō-kōr'ti-kō-trō'fik hor'mōn) Hormone that stimulates the adrenal cortex to release its hormones.

advance scheduling (ad-vans' sked'jŭl-ing) Booking an appointment several weeks or even months in advance.

adverse effect (ad-vĕrs' e-fekt') An unintended negative reaction to a medication or treatment. Adverse effects are potentially more harmful than side effects, but are less common.

AED See **automated external defibrillator**.

aerobes (âr'ōbz) Bacteria that grow best in the presence of oxygen.

aerobic respiration (âr-ō'bik res'pir-ă'shŭn) A process that requires large amounts of oxygen and uses glucose to make ATP.

afebrile (ă-feb'rĭl) Having a body temperature within one's normal range.

afferent arterioles (af'ĕr-ĕnt ahr-tĕr'ĕ-ōls) Structures that deliver blood to the glomeruli of the kidneys.

afferent nerves (af'ĕr-ĕnt nĕrvs) Sensory nerves that are responsible for detecting sensory information from the environment or even from inside the body and taking it to the CNS for interpretation.

affiliation agreement (ă-fil'i-ă-shŭn ă-grĕ'mĕnt) An agreement that applied training participants must sign that states the expectations of the facility and the expectations of the student.

agar (ă'gahr) A gelatin-like substance derived from seaweed that gives a culture medium its semisolid consistency.

age analysis (ăj ă-nal'i-sis) The process of clarifying and reviewing past-due accounts by age from the first date of billing.

agenda (ă'jĕn-dă) The list of topics discussed or presented at a meeting, in order of presentation.

agent (ă'jĕnt) (legal) A person who acts on a physician's behalf while performing professional tasks; (clinical) an active principal or entity that produces a certain effect, for example, an infectious agent.

agglutination (ă-glŭ-ti-nă'shŭn) The clumping of red blood cells following a blood transfusion.

aggressive (ă-gres'iv) Imposing one's position on others or trying to manipulate them.

agonist (ag'ōn-ist) See **antagonist**.

agranular leukocyte (ă-gran'yŭ-lăr lŭ'kō-sĭt) A type of leukocyte (white blood cell) with a solid nucleus and clear cytoplasm; includes lymphocytes and monocytes.

agranulocyte (ă-grăn'ŭ-lō-sĭt) See **agranular leukocyte**.

AIDS See **Acquired Immune Deficiency Syndrome**.

albumins (al-bŭ'mins) The smallest of the plasma proteins. Albumins are important for pulling water into the bloodstream to help maintain blood pressure.

alcohol-based hand disinfectants (AHD) (al'kō-hol bāsd hand dis-infek'tānts) Gels, foams, or liquids with an alcohol content of 60% to 95% that are used for hand disinfection.

aldosterone (al-dos'tĕr-ōn) A hormone produced in the adrenal glands that acts on the kidney. It causes the body to retain sodium and excrete potassium. Its role is to maintain blood volume and pressure.

alimentary canal (al'i-men'tăr-ĕ kă-nal') The organs of the digestive system that extend from the mouth to the anus.

allele (ă-lĕl') Any one of a pair or series of **genes** that occupy a specific position on a specific **chromosome**.

allergen (al'ĕr-jĕn) An antigen that induces an allergic reaction.

allergic rhinitis (ă-lĕr'jik rĭ-nĭ'tis) A hypersensitivity reaction to various airborne allergens.

allergist (al'ĕr-jĭst) A specialist who diagnoses and treats physical reactions to substances including mold, dust, fur, pollen, foods, drugs, and chemicals.

allopathy (al-op'ă-thĕ) The usual medical practice of physicians and other health professionals; also known as conventional medicine.

allowed charge (ă-low'd chahrj) The amount that is the most the payer will pay any provider for each procedure or service.

alopecia (al-ō-pĕ'shĕ-ă) The clinical term for baldness.

alphabetic filing system (ăl'fă-bĕt'ĭk fĭ'ling sis'təm) A filing system in which the files are arranged in alphabetical order, with the patient's last name first, followed by the first name and middle initial.

Alphabetic Index (al'fă'bet-ik in'deks) One of two ways diagnoses are listed in the ICD manual. They appear in alphabetical order with their corresponding diagnosis codes.

alternative medicine (awl-tĕr'nă-tĭv med'i-sin) The type of medicine used in place of conventional medicine to promote health and treat disease.

alveolar glands (al-vĕ'ō-lăr glands) Glands that make milk under the influence of the hormone **prolactin**.

alveoli (al-vĕ'ō-lĭ) Clusters of air sacs in which the exchange of gases between air and blood takes place; located in the lungs.

amblyopia (am'blĕ-ō'pĕ-ă) Poor vision in one eye without a detectable cause.

amenorrhea (ă-men'ō-rĕ'ă) Absence or abnormal cessation of the menses.

American Association of Medical Assistants (AAMA) (ă-mer'i-kăn ă-sō'sĕ-ă'shŭn med'i-kăl ă-sis'tānts) The professional organization that certifies medical assistants and works to maintain professional standards in the medical assisting profession.

American Medical Technologists (AMT) (ă-mer'i-kăn med'i-kăl tek-nol'ō-jĭsts) The registering organization for medical assistants that provides online continuing education, certification information, and member news.

Americans with Disabilities Act (ADA) (ă-mer'i-kănz dis'ă-bil'i-tĕz akt) A US civil rights act forbidding discrimination against people because of a physical or mental handicap.

amino acid (ă-mē'nō as'id) Natural organic compound found in plant and animal foods and used by the body to create protein.

amnion (am'nē-on) The innermost membrane enveloping the embryo and containing amniotic fluid.

amount to administer (A) (ă-mownt ad-min'i-stīr') The amount of medication the patient will receive.

AMT See **American Medical Technologists**.

anabolism (ă-nab'ō-lizm) The stage of metabolism in which substances such as nutrients are changed into more complex substances and used to build body tissues.

anaerobe (an'ār-ōb) A bacterium that grows best in the absence of oxygen.

anal canal (ā'nāl kā-nal') The last few centimeters of the rectum.

anaphase (an'ă-fāz) The period of mitosis when the centromeres divide and pull the chromosomes (formerly chromatids) toward the centrioles at opposite sides of the cell.

anaphylactic shock (an'ă-fi-lak'tik shok) A severe, often fatal form of shock characterized by smooth muscle contraction and capillary dilation initiated by cytotoxic (IgE class) antibodies.

anaphylaxis (an'ă-fi-lak'sis) A severe allergic reaction with symptoms that include respiratory distress, difficulty in swallowing, pallor, and a drastic drop in blood pressure that can lead to circulatory collapse.

anatomical position (an-ă-tom'i-kāl pō-zish'ōn) When the body is standing upright and facing forward with the arms at the side and the palms of the hands facing forward.

anatomy (ă-nat'ō-mē) The scientific term for the study of body structure.

anemia (ă-nē'mē-ă) A condition characterized by low red blood cell count. This condition decreases the ability to transport oxygen throughout the body.

anergic reaction (an-er'jik rē-ăk'shən) A lack of response to skin testing that indicates the body's inability to mount a normal response to invasion by a pathogen.

anesthesia (an'es-thē'zē-ă) A loss of sensation, particularly the feeling of pain.

anesthetic (an'es-thet'ik) A medication that causes anesthesia.

anesthetist (ă-nes'thē-tist) A specialist who uses medications to cause patients to lose sensation or feeling during surgery.

aneurysm (an'yūr-izm) A serious and potentially life-threatening bulge in the wall of a blood vessel.

angiography (an-jē-og'ră-fē) An X-ray examination of a blood vessel, performed after the injection of a contrast medium, that evaluates the function and structure of one or more arteries or veins.

annotate (an'ō-tāt') To underline or highlight key points of a document or to write reminders, make comments, and suggest actions in the margins.

anorexia nervosa (an'ō-rek'sē-ă nēr-vō'să) An eating disorder in which people starve themselves because they fear that if they lose control of eating they will become grossly overweight.

antagonist (an-tag'ō-nist) A muscle that produces the opposite movement of the **prime mover**.

antecubital space (an-te-kyū'bi-tāl spās) The inner side or bend of the elbow; the site at which the brachial artery is felt or heard when a pulse or blood pressure is taken.

anterior (an-tēr'ē-ōr) Anatomical term meaning toward the front of the body; also called ventral.

anthracosis (an'thră-kō'sis) Chronic lung disease caused by the inhalation of coal deposits; also known as black lung disease.

antibodies (ăn'ti-bod'ēs) Highly specific proteins that attach themselves to foreign substances in an initial step in destroying such substances, as part of the body's defenses.

antibody-mediated response (an'ti-bod-ē mē'dē-ăt-ed rē-spons') The part of our body's immune response that occurs when B cells respond to antigens by becoming plasma cells, which make antibodies that attach to antigens.

anticoagulants (an'tē-kō-ag'yū-lăntz) Substances that prevent clotting.

antidiuretic hormone (ADH) (an'tē-dī-yūr-et'ik hōr'mōn) A hormone that increases water reabsorption, which decreases urine production and helps to maintain blood pressure.

antigens (an'ti-jenz) Foreign substances that stimulate white blood cells to create antibodies when they enter the body.

antihistamines (an'tē-his'tă-mēnz) Medications used to treat allergies.

antimicrobial (an'tē-mī-krō'bē-ăl) An agent that kills microorganisms or suppresses their growth.

antioxidant (an'tē-ok'si-dănt) Chemical agent that fights cell-destroying chemical substances called free radicals.

antiseptic (an'ti-sep'tik) A cleaning product used on human tissue as an anti-infection agent.

antivirus software (an'tē-vī'rūs sahft'wēr) Software that prevents and removes computer viruses. Such programs may also detect and remove adware and spyware.

anuria (an-yū'rē-ă) The absence of urine production.

aortic semilunar valve (ă-ōr'tik sem'ē-lū'năr valv) Heart valve that is a semilunar valve and that is situated between the left ventricle and the aorta.

apex (ă'peks) The left lower corner of the heart, where the strongest heart sounds can be heard.

APGAR (ap'gar) A test performed 1 minute and 5 minutes after a baby is born to determine how well the baby is breathing and how well the heart is working. Its five categories are respiratory effort, heart rate, skin color, reflexes, and muscle tone.

apical (ap'i-kāl) Located at the **apex** of the heart.

apnea (ap'nē-ă) The absence of respiration.

apocrine gland (ap'ō-krin glănd) A type of sweat gland. It produces a thicker type of sweat than other sweat glands and contains more proteins.

aponeurosis (ap'ō-nū-rō'sis) A tough, sheet-like structure that is made of fibrous connective tissue. It typically attaches muscles to other muscles.

apothecary system (ă-poth'ē-kăr-ēs'is'tēm) An older system of measurement that includes units such as fluid ounces, fluid drams, pints, and quarts.

appendicitis (ă-pen'di-sītis) Inflammation of the appendix.

appendicular (ap'en-dik'yū-lăr) The division of the skeletal system that consists of the bones of the arms, legs, pectoral girdle, and pelvic girdle.

applied training (ă-plīd trăn'ing) An opportunity to work in a medical facility to gain the essential on-the-job

experience for beginning your new career, sometimes known as an externship or practicum.

applied training coordinator (ă-plīd trān'ing kō-ōr'di-nā-tōr) A professional who procures applied training sites and qualifies, or assesses, them to make certain that they provide a thorough educational experience. May also be known as a clinical coordinator.

approximate (ă-prōk's i māt) To bring the edges of a wound together so that the tissue surfaces are close in order to protect the area from further contamination and to minimize scar and scab formation.

aqueous humor (ă'kwē-ūs hyū'mōr) A liquid produced by the eye's ciliary body that fills the space between the cornea and the lens.

arbitration (ahr'bi-trā'shūn) A process in which opposing sides choose a person or persons outside the court system, often someone with special knowledge in the field, to hear and decide a dispute.

areflexia (ă-rē-flek'sē-ă) The absence of reflexes.

areola (ă-rē'ō-lă) The pigmented area that surrounds the nipple.

aromatherapy (ă-rō'mă-thār'ă-pē) The use of essential oil extracts or essences from flowers, herbs, and trees to promote health and well-being.

arrector pili (ă-rek'tōr pī'lī) Muscles attached to most hair follicles and found in the dermis.

arrhythmia (ă-ridh'mē-ă) Irregularity in heart rhythm.

arterial blood gases (ahr-tēr'ē-ăl blūd gās'sez) A test that measures the amount of gases, such as oxygen and carbon dioxide, dissolved in arterial blood.

arthritis (ahr-thrī'tis) A general term meaning joint inflammation.

arthrography (ahr-throg'ră-fē) A radiologic procedure performed by a radiologist, who uses a contrast medium and fluoroscopy to help diagnose abnormalities or injuries in the cartilage, tendons, or ligaments of the joints—usually the knee or shoulder.

arthroscopy (ahr-thros'kō-pē) A procedure in which an orthopedist examines a joint, usually the knee or shoulder, with a tubular instrument called an arthroscope; also used to guide surgical procedures.

articular cartilage (ahr-tik'yū-lăr kahr'ti-lăj) The cartilage that covers the epiphysis of long bones.

articulations (ahr-tik'yū-lă'shūnz) The areas where bones are joined together; joints.

artifact (ahr'ti-fakt) Any irrelevant object or mark observed when examining specimens or graphic records that is not related to the object being examined—for example, a foreign object visible through a microscope or an erroneous mark on an ECG strip.

asbestosis (as-bes-tō'sis) Chronic lung disease caused by the inhalation of asbestos fibers.

ascending colon (ă-send'ing kō'lōn) The segment of the large intestine that runs up the right side of the abdominal cavity.

ascending tracts (ă-send'ing trakts) The tracts of the spinal cord that carry sensory information to the brain.

asepsis (ă-sep'sis) The condition in which pathogens are absent or controlled.

assault (ă-sawlŧ) The open threat of bodily harm to another.

assertive (ă-sēr'tiv) Being firm and standing up for oneself while showing respect for others.

asset (as'-ět) An item owned by the practice that has a dollar value, such as the medical practice building, office equipment, or accounts receivable.

assignment of benefits (ă-sīn'mēnt ben'ē-fits) An authorization for an insurance carrier to pay a physician or practice directly.

asthma (az'mă) A condition in which the tubes of the bronchial tree become obstructed due to inflammation.

astigmatism (ă-stig'mă-tizm) A condition in which the cornea has an abnormal shape, which causes blurred images during near or distant vision.

astrocytes (ăs'trō-sīts) Star-shaped cells within the nervous system that anchor blood vessels to the nerve cells.

atelectasis (at'ē-lek'tă-sis) The collapse of a lung because of fluid, air, pus, or blood.

atherosclerosis (ath'ēr-ō-skler-ō'sis) The accumulation of fatty deposits along the inner walls of arteries.

atlas (at'lăs) The first cervical vertebra.

atoms (at'ōmz) The simplest units of all matter.

atria (ă'trē-ă) [*Singular: atrium*] Chambers of the heart that receive blood from the veins and circulate it to the ventricles.

atrial natriuretic peptide (ă'trē-ăl nă'trēyū-ret'ik pep'tid) A hormone secreted by the heart that regulates blood pressure.

atrioventricular bundle (ă'trē-ō-ventrik'yū-lar būn'dēl) A structure that is located between the ventricles of the heart and that sends the electrical impulse to the Purkinje fibers.

atrioventricular node (AV node) (ă'trē-ō-ventrik'yū-lar nōd) A node that is located between the atria of the heart. After the electrical impulse reaches the atrioventricular node, the atria contract and the impulse is sent to the ventricles.

atrioventricular septum (ă'trē-ō-ventrik'yū-lar sep'tūm) The wall separating the upper atrial chambers from the lower ventricular chambers of the heart.

attitude (at'i-tūd) A disposition to act in a certain way.

audiologist (aw-dē-ol'ōjist) A healthcare specialist who focuses on evaluating and correcting hearing problems.

audiometer (aw-dē-om'ē-ter) An electronic device that measures hearing acuity by producing sounds in specific frequencies and intensities.

audit (aw'dit) To examine and review a group of patient records for completeness and accuracy—particularly as related to their ability to back up the charges sent to health insurance carriers for reimbursement.

auricle (aw'r-i-kēl) The outside part of the ear, made of cartilage and covered with skin.

auscultated blood pressure (aws'kūl-tăt-ēd blūd presh'ūr) Blood pressure as measured by listening with a stethoscope.

auscultation (aws'kūl-tă'shūn) The process of listening to body sounds.

authorization (aw'thōr-i-ză'shūn) A form that explains in detail the standards for the use and disclosure of patient information for purposes other than treatment, payment, or healthcare operations.

autoclave (aw'tō-klāv) A device that uses pressurized steam to sterilize instruments and equipment.

autoimmune disease (aw'tō-i-myūn'di-zēz') Any condition in which the

- body attacks its own antigens, causing illness to the patient.
- automated external defibrillator (AED)** (aw'tō-mā-tēd eks-tēr'nāl dē-fib'ri-lā-tōr) A computerized defibrillator programmed to recognize lethal heart rhythms and deliver an electric shock to restore a normal rhythm.
- automated voice response unit** (aw'tō-mā'tēd voys rē-spons' yū'nit) Automated answering unit with a recorded voice that offers the caller various options for routing the call.
- automatic puncturing devices** (aw'tō-mat'ik punġk'shūr-ing dē-vīs'iz) A type of lancet that is spring loaded, is self-contained, and has a mechanically controlled skin puncture depth.
- autonomic** (aw'tō-nom'ik) A division of the peripheral nervous system that connects the central nervous system to viscera such as the heart, stomach, intestines, glands, blood vessels, and bladder.
- autonomic nervous system** (aw'tō-nom'ik nēr'vūs sis'tēm) A system that is in charge of the body's automatic functions, such as the respiratory and gastrointestinal systems.
- autopsy** (aw'top-sē) The examination of a cadaver to determine or confirm the cause of death.
- autosome** (aw'tō-sōm) A chromosome that is not a sex chromosome.
- axial** (ak'sē-āl) The division of the skeletal system that consists of the skull, vertebral column, and rib cage.
- axilla** (ak-sil'ā) Armpit; one of the four locations for temperature readings.
- axis** (ak'-sis) The second vertebra of the neck on which the head turns.
- axon** (ak'son) A type of nerve fiber that is typically long and branches far from the cell body. Its function is to send information away from the cell body.
- Ayurveda** (ī'yūr-vā'd'ā) A form of medicine, originated in India, that uses herbal preparations, dietary changes, exercises, and meditation to restore health and promote well-being.
- bacillus** (bā-sil'ūs) A rod-shaped bacterium.
- bacterial spore** (bak-tēr'ē-āl spōr) A primitive, thick-walled reproductive body capable of developing into a new individual; resistant to killing through disinfection.
- balance billing** (bal'āns bil'ing) Billing a patient for the difference between a higher usual fee and a lower allowed charge.
- balloon angioplasty** (bā-lūn' an'jē-ō-plas'tē) A procedure using a slender, hollow tube passed through a coronary artery to compress a blockage in the artery.
- bandwidth** (bānd'width) A measurement, calculated in bits or bytes, of how much information can be sent or processed with one single instruction.
- barium enema** (bar'ē-ūm en'ē-mā) A radiologic procedure performed by a radiologist who administers barium sulfate through the anus, into the rectum, and then into the colon to help diagnose and evaluate obstructions, ulcers, polyps, diverticuloses, tumors, or motility problems of the colon or rectum; also called a lower GI (gastrointestinal) series.
- barium swallow** (bar'ē-ūm swahl'ō) A radiologic procedure that involves oral administration of a barium sulfate drink to help diagnose and evaluate obstructions, ulcers, polyps, diverticuloses, tumors, or motility problems of the esophagus, stomach, duodenum, and small intestine; also called an upper GI (gastrointestinal) series.
- baroreceptors** (bar'ō-rē-sep'terz) Structures, located in the aorta and carotid arteries, that help regulate blood pressure.
- Bartholin's glands** (bahr'tō-līn glandz) Glands lateral to the vagina that produce mucus for lubrication of the vagina.
- bases** (bā'sēz) Electrolytes that release hydroxyl ions in water.
- basophil** (bā-sō-fil) A type of granular leukocyte that produces the chemical histamine, which aids the body in controlling allergic reactions and other exaggerated immunologic responses.
- battery** (bat'ēr-ē) An action that causes bodily harm to another.
- behavior modification** (bē-hāv'yōr mod'ī-fi-kā'shūn) The altering of personal habits to promote a healthier lifestyle.
- benefits** (ben'ē-fits) Payments for medical services.
- benign** (bē-nīn') A noncancerous or non-malignant growth or condition.
- benign prostatic hypertrophy** (bē-nīn' pros-tat'ik hī-pēr'trō-fē) A noncancerous enlargement of the prostate gland.
- bicarbonate ions** (bī-kahr'bōn-āt ī'onz) Elements formed when carbon dioxide gets into the bloodstream and reacts with water. In the alimentary canal, these ions neutralize acidic chyme arriving from the stomach.
- bicuspid** (bī-kūs'pidz) Teeth with two cusps. There are two in front of each set of molars.
- bicuspid valve** (bī-kūs'pid valv) Heart valve that has two cusps and that is located between the left atrium and the left ventricle. Also known as the mitral valve.
- bile** (bīl) A substance created in the liver and stored in the gallbladder. Bile is a bitter, yellow-green fluid that is used in the digestion of fats.
- bilirubin** (bil'i-rū-bin) A bile pigment formed by the breakdown of hemoglobin in the liver.
- bilirubinuria** (bil'i-rū-bi-nyūr'ē-ā) The presence of bilirubin in the urine; one of the first signs of liver disease or conditions that involve the liver.
- biliverdin** (bil'i-vēr-dīn) A pigment released when a red blood cell is destroyed.
- biochemistry** (bīō-kem'is-trē) The study of matter and chemical reactions in the body.
- bioelectromagnetic-based therapies** (bīō-ē-lek'trō-mag'nēt-ik bās-ēd thār'ā-pēz) The use of measurable energy fields in such things as magnetic therapy, millimeter wave therapy, sound energy therapy, and light therapy.
- bioethics** (bīō-ēth'iks) Principles of right and wrong in issues that arise from medical advances.
- biofeedback** (bīō-fēd'bak) A type of therapy in which an individual learns how to control involuntary body responses in order to promote health and treat disease.
- biofield therapies** (bīō-fēld thār'ā-pēz) Treatments that affect the energy fields that surround and penetrate the human body in order to promote health and well-being.
- biohazardous materials** (bīō-haz'ārd-ūs mā-tēr'ē-ālz) Biologic agents that can spread disease to living things.
- biohazardous waste container** (bīō-haz'ārd-ūs wāst kōn-tā'nēr) A leakproof, puncture-resistant container, color-coded red or labeled with a biohazard symbol, that is used to store and dispose of contaminated supplies and equipment.

biohazard symbol (bī'ō-haz'ārd sim'bōl) A symbol that must appear on all containers used to store waste products, blood, blood products, or other specimens that may be infectious.

biological indicator (bī'ō-loj'i-kālin'di-kā-tōr) An indicator consisting of bacterial spores that is used as a quality control method in autoclaves to confirm that sterilization has occurred.

biopsy (bī-op'sē) The removal and examination of a sample of tissue from a living body for diagnostic purposes.

biopsy specimen (bī'op'sē spes'i-mēn) A small amount of tissue removed from the body for examination under a microscope to diagnose an illness.

bioterrorism (bīo-ter'ōr-izm) The intentional release of a biologic agent with the intent to harm individuals.

birthday rule (bīrth'dā rūl) A rule that states that the insurance policy of a policyholder whose birthday comes first in the year is the primary payer for all dependents.

blastocyst (blas'tō-sist) A morula that travels down the uterine tube to the uterus and is invaded with fluid. It then implants into the wall of the uterus.

bloodborne pathogen (blūd'bōrn path'ō-jēn) A disease-causing microorganism carried in a host's blood and transmitted through contact with infected blood, tissue, or body fluids.

blood-brain barrier (blūd brān bar'ē-ēr) A structure that is formed from tight capillaries to protect the tissues of the central nervous system from certain substances.

B lymphocyte (bē lim'fō-sīt) A type of nongranular leukocyte that produces antibodies to combat specific pathogens.

board-certified physician (bōrd sēr'ti-fīd fi-zish'ūn) A licensed practitioner who has obtained education and licensing for 9 to 12 years and taken multiple tests known as board tests.

body (bod'ē) Single-spaced lines of text that are the content of a business letter.

body language (bod'ē lang'gwāj) Non-verbal communication, including facial expressions, eye contact, posture, touch, and attention to personal space.

body mass index (BMI) (bod'ē mas in'deks) A reliable indicator of healthy weight that is calculated based on height and weight.

body mechanics (bod'ē mē-kan'iks) The application of physical principles to achieve maximum efficiency and to limit risk of physical stress or injury to the practitioner of physical therapy, massage therapy, or chiropractic or osteopathic manipulation.

body surface area (BSA) (bod'ē sūr'fās ār'ē-ā) The area of the external surface of the body, expressed in square meters (m²); used to calculate metabolic, electrolyte, and nutritional requirements; drug dosage; and expected pulmonary function measurements.

bolus (bō'lūs) The mass created when food is combined with saliva and mucus.

bone conduction (bōn kōn-dūk'shūn) The process by which sound waves pass through the bones of the skull directly to the inner ear, bypassing the outer and middle ears.

bookkeeping (buk kēp'ing) The systematic recording of business transactions.

botulism (boch'ū-lizm) A life-threatening type of food poisoning that results from eating improperly canned or preserved foods that have been contaminated with the bacterium *Clostridium botulinum*.

boundaries (bown'dār-ēz) A physical or psychological space that indicates the limit of appropriate versus inappropriate behavior.

Bowman's capsule (bō'mānz kap'sūl) A capsule that surrounds the **glomerulus** of the kidney.

brachial artery (brā'kē-āl ahr'tēr-ē) An artery that provides a palpable pulse and audible vascular sounds in the antecubital space (the bend of the elbow).

brachytherapy (brak-ē-thār'ā-pe') A radiation therapy technique in which a radiologist places temporary radioactive implants close to or directly into cancerous tissue; used for treating localized cancers.

bradycardia (brad'ē-kahr'dē-ā) A slow heart rate; usually less than 60 beats per minute.

brain stem (brān stem) A structure that connects the cerebrum to the spinal cord.

breach of contract (brēch kon'trakt) The violation of or failure to live up to a contract's terms.

bronchi (brong'kī) The two branches of the trachea that enter the lungs.

bronchial tree (brong'kē-al trē) A series of tubes that begins where the distal end of the trachea branches.

bronchioles (brong'kē-ōlz) A part of the respiratory tract that branches from the tertiary bronchi.

buccal (būk'āl) Between the cheek and gum.

budget (būj'ēt) The total sum of money allocated for a particular purpose or period of time.

buffy coat (buf'ē kōt) The layer between the packed red blood cells and plasma in a centrifuged blood sample; this layer contains the white blood cells and platelets.

bulbourethral glands (būl'bō-yū-rē'thrāl glāndz) Glands that lie beneath the prostate and empty their fluid into the urethra. Their fluid aids in sperm movement.

bulimia nervosa (bū-līm'ē-ā nēr-vō'sā) An eating disorder in which people eat a large quantity of food in a short period of time (bingeing) and then attempt to counter the effects of bingeing by self-induced vomiting, use of laxatives or diuretics, and/or excessive exercise.

bundled codes (būn'dēld kōds) When healthcare services that are usually separate are considered as a single entity for purposes of classification and payment.

bundle of His (būn'dēl hiss) Also known as the AV bundle, this is the node located between the ventricles of the heart that carries the electrical impulse from the AV node to the bundle branches.

burnout (būrn'owt) The end result of prolonged periods of stress without relief. Burnout is an energy-depleting condition that can affect one's health and career. It can be common for those who work in healthcare.

bursitis (būr-sīt'is) Inflammation of a bursa.

butterfly system (būt'ēr-flī sis'tēm) A type of needle used to draw blood from patients with small or fragile veins. Sometimes called a winged infusion set, it has flexible wings attached to the needle and a length of flexible tubing.

CABG See **coronary artery bypass graft**.

calcaneus (kal-kā'nē-ūs) The largest tarsal bone; also called the heel bone.

calcitonin (kal-si-tō'nin) A hormone produced by the thyroid gland that lowers blood calcium levels by activating osteoblasts.

calibrate (kal'i-brāt) To determine the caliber of; to standardize a measuring instrument.

calibrated spoon (kal'i-brā-tēd spūn) A spoon that has special markings, or calibrations, that allow you to measure a dose of liquid medication.

calibration syringe (kal'i-brā'shūn sir-inj') A standardized measuring instrument used to check and adjust the volume indicator on a spirometer.

calorie (kal'ōr-ē) A unit used to measure the amount of energy food produces; the amount of energy needed to raise the temperature of 1 kg of water by 1°C.

calyces (kal'ih-sēz) Small cavities of the renal pelvis of the kidney.

CAM (kam) The acronym for complementary and alternative medicine. Complementary medicine is used with conventional medicine. Alternative medicine is used in place of conventional medicine.

canaliculi (kan-ā-lik'yū-lī) Tiny canals that connect lacunae to each other.

cancellous (kan-sēl'ūs) Bone also known as spongy bone. It contains spaces within it containing the red bone marrow.

capillary (kap'i-lar-ē) Branches of arterioles and the smallest type of blood vessel.

capillary puncture (kap'i-lar-ē pungk'shūr) A blood-drawing technique that requires a superficial puncture of the skin with a sharp point.

capitation (kap'i-tā'shūn) A payment structure in which a health maintenance organization prepays an annual set fee per patient to a physician.

carboxyhemoglobin (kahr-bok'sē-hē'mō-glō'bin) The term used when the hemoglobin of red blood cells is carrying carbon dioxide.

carboxypeptidase (kahr-bok'sē-pep'ti-dās) A pancreatic enzyme that digests proteins.

carcinogen (kahr-sin'ō-jen) A factor that is known to cause the formation of cancer.

cardiac catheterization (kahr'dē-ak kath'ē-tēr-ī-zā'shūn) A diagnostic method in which a catheter is inserted into a vein or an artery in the arm or leg and passed through blood vessels into the heart.

cardiac cycle (kahr'dē-ak sī'kēl) The sequence of contraction and relaxation that makes up a complete heartbeat.

cardiac output (kahr'dē-ak owt'put) The product of heart rate and stroke volume, measured in liters per minute; the amount of blood that is pumped by the heart in 1 minute.

cardiac rehabilitation (kahr'dē-ak rē'hā-bil'i-tā'shūn) A systematic program of exercise and nutritional, behavioral, and vocational counseling to optimize the recovery and physiologic capacity of the patient with cardiovascular disease.

cardiac sphincter (kahr'dē-ak sfing'k'tēr) The valve-like structure composed of a circular band of muscle at the juncture of the esophagus and stomach. Also known as the esophageal sphincter.

cardiologist (kahr'dē-ol'ō-jist) A specialist who diagnoses and treats diseases of the heart and blood vessels (cardiovascular diseases).

carditis (kahr-dī'tis) Inflammation of the heart.

carpal (kahr'pāl) Bone of the wrist.

carpal tunnel syndrome (kahr'pāl tūn'ēl sin'drōm) A painful disorder caused by compression of the median nerve in the carpal tunnel of the wrist.

carrier (kar'ē-ēr) A reservoir host who is unaware of the presence of a pathogen and so spreads the disease while exhibiting no symptoms of infection.

cash flow statement (kash flō stāt'mēnt) A statement that shows the cash on hand at the beginning of a period, the income and disbursements made during the period, and the new amount of cash on hand at the end of the period.

cashier's check (ka-shēr-z chek) A bank check issued by a bank on bank paper and signed by a bank representative; usually purchased by individuals who do not have checking accounts.

cast (kast) Cylinder-shaped elements with flat or rounded ends, differing in composition and size, that form when protein from the breakdown of cells accumulates and precipitates in the kidney tubules and is washed into the urine. A rigid, external dressing, usually made of plaster or fiberglass, that is molded to the contours of the body part to which it is applied; used to immobilize a fractured or dislocated bone.

catabolism (kā-tab'ō-lizm) The stage of metabolism in which complex substances, including nutrients and body tissues, are broken down into simpler substances and converted into energy.

cataracts (kat'ār-akt) Cloudy areas that form in the lens of the eye that prevent light from reaching visual receptors.

category (kat'ē-gōr'ē) In both ICD-9 and ICD-10, the first three digits of the diagnosis code.

catheter-associated urinary tract infection (CAUTI) (kath'ē-tēr ā-sō'sē-āt-ēd yūr'i-nar-ē trakt infek'shūn) A urinary tract infection that may be caused by long-term use of urinary catheters; the longer the catheter is in place, the greater the chance of infection.

catheterization (kath'ē-ter-ī-zā'shun) The procedure during which a catheter is inserted into a vessel, an organ, or a body cavity.

caudal (kaw'dāl) See **inferior**.

CD-ROM (sē'dē-rōm) A compact disc that contains software programs; an abbreviation for "compact disc—read-only memory."

cecum (sē'kūm) The first section of the large intestine.

celiac disease (sē'lē-ak di-zēz') An intolerance to gluten that causes an immune response in the body and reduces the absorption of nutrients in the small intestine.

cell body (sel bōd'ē) The portion of the neuron that contains the nucleus and organelles.

cell-mediated response (sel mē'dē-āt-id rē-spons') The part of our body's immune response that occurs when T cells bind to antigens on cells and attack the antigens directly.

cell membrane (sel mem'brān) The outer limit of a cell that is thin and selectively permeable. It controls the movement of substances into and out of the cell.

cells (selz) The smallest living units of structure and function.

cellulitis (sel-yū-lī'tis) Inflammation of cellular or connective tissue.

cellulose (sel'yū-lōs) A type of carbohydrate that is found in vegetables and cannot be digested by humans; commonly called fiber.

Celsius (centigrade) (sel'sē-ūs) One of two common scales for measuring temperature; measured in degrees Celsius, or °C.

Centers for Medicare and Medicaid Services (CMS) (sen'tērs med'i-kār medi-kād sēr'vis-ez) A congressional agency designed to handle Medicare and Medicaid insurance claims. It was

formerly known as the Health Care Financing Administration.

central line (sen'trāl līn) A catheter placed in a large vein, usually in the neck, chest, or groin, that is used to give fluids or medications.

central line–associated bloodstream infections (CLABSI) (sen'trāl līn ă-sō'sē-ăt-ēd blūd'strēm in-fek'shūnz) Bloodstream infections caused by the entry of infectious microorganisms into the bloodstream through a central line.

central nervous system (CNS) (sen'trāl nēr'vūs sis'tēm) A system that consists of the brain and the spinal cord.

central processing unit (CPU) (sen'trāl pros'es-ing yū'nīt) A microprocessor, the primary computer chip responsible for interpreting and executing programs.

centrifuge (sen'tri-fyūzh) A device used to spin a specimen at high speed until it separates into its component parts.

centrioles (sen'trē ōlz) Two cylinder-shaped organs near the cell nucleus that are essential for cell division, by equally dividing chromosomes to the daughter cells.

cerebellum (ser'ē-bel'ūm) An area of the brain inferior to the cerebrum that coordinates complex skeletal muscle coordination.

cerebrospinal fluid (CSF) (ser'ē-brō-spī-nāl flūo'id) The fluid in the subarachnoid space of the meninges and the central canal of the spinal cord.

cerebrovascular accident (ser'ē-brō-vas'kyū-lăr ak'si-dēnt) A stroke; caused by a hemorrhage in the brain or more often by a clot lodged in a cerebral artery.

cerebrum (ser'ē-brūm) The largest part of the brain; it mainly includes the cerebral hemispheres.

Certificate of Waiver tests (sēr'ti-fi-kūt wāv'ēr tests) Laboratory tests that pose an insignificant risk to the patient if they are performed or interpreted incorrectly, are simple and accurate to such a degree that the risk of obtaining incorrect results is minimal, and have been approved by the Food and Drug Administration for use by patients at home; laboratories performing only Certificate of Waiver tests must meet less stringent standards than laboratories that perform tests in other categories.

certification (sēr'ti-fi-kă'shūn) The attainment of board approval and credentialing in a specialty.

certified check (sēr'ti-fid chek) A payer's check written and signed by the payer, which is stamped "certified" by the bank. The bank has already drawn money from the payer's account to guarantee that the check will be paid.

Certified Medical Assistant (CMA) (sēr'ti-fid med'i-kăl ă-sis'tănt) A medical assistant whose knowledge about the skills of medical assistants, as summarized by the 2003 AAMA Role Delineation Study areas of competence, has been certified by the Certifying Board of the American Association of Medical Assistants (AAMA).

cerumen (sē-rū'mēn) A wax-like substance produced by glands in the ear canal; also called earwax.

cervical enlargement (sēr'vi-kăl en-lahrj'mēnt) The thickening of the spinal cord in the neck region.

cervical orifice (sēr'vi-kăl ōr'i-fis) The opening of the uterus through the cervix into the vagina.

cervicitis (ser-vi-sī'tis) Inflammation of the cervix.

cervix (sēr'viks) The lowest portion of the uterus that extends into the vagina.

cesarean section (se-zār'ē-ăn sek'shūn) A surgical incision of the abdomen and uterus to deliver a baby transabdominally.

chain of command (chăn kō-mand') A command hierarchy where a group of people are committed to carrying out orders from the highest authority.

chain of custody (chăn kūs'tō-dē) A procedure for ensuring that a specimen is obtained from a specified individual, is correctly identified, is under the uninterrupted control of authorized personnel, and has not been altered or replaced.

CHAMPVA (Civilian Health and Medical Program of the Veterans Administration) (si-vil'yăn helth med'i-kăl prō'gram) A type of health insurance that covers the expenses of families (dependent spouses and children) of veterans with total, permanent, and service-connected disabilities. It also covers the surviving families of veterans who die in the line of duty or as a result of service-connected disabilities.

chancere (shang'ker) A painless ulcer that may appear on the tongue, the lips, the genitalia, the rectum, or elsewhere.

chapters (chap-tērz) The breakdown of diagnosis codes by body system or

disease. There are 17 chapters in ICD-9 and 21 in ICD-10.

charge slip (chahrj slip) The original record of services performed for a patient and the charges for those services.

check (chek) A bank draft or order written by a payer that directs the bank to pay a sum of money on demand to the payee.

CHEDDAR (ched'er) **C:** Chief complaint. **H:** History. **E:** Examination. **D:** Details of problem and complaints. **D:** Drugs and dosage. **A:** Assessment. **R:** Return visit information or referral, if applicable.

chemical digestion (kem'i-kăl di-jes'chūn) The breaking down of food for use by the body caused by enzymes in the body such as amylase.

chemistry (kem'is-trē) The study of the composition of matter and how matter changes.

chemoreceptor (kēm'mō-rē-sep'tōr) Any cell that is activated by a change in chemical concentration and results in a nerve impulse. The olfactory, or smell, receptors in the nose are an example of a chemoreceptor.

Cheyne-Stokes respirations (chăn stōks res'pir-ă'shūnz) A pattern of breathing that gradually alternates between deep and shallow breaths with a period of apnea or no breathing that can last from 5 to 40 seconds.

chief cells (chēf sēlz) Cells in the lining of the stomach that secrete pepsinogen.

chief complaint (CC) (chēf kōm-plānt) The patient's main issue of pain or ailment.

chiropractor (kīrō-prak'tōr) A licensed practitioner who uses a system of therapy, including manipulation of the spine, to treat illness or pain. This treatment is done without drugs or surgery.

chlamydia (klă-mid'ē-ă) A common bacterial STI caused by bacterium *Chlamydia trachomatis* that can lead to PID in women.

cholangiography (kō-lan-jē-og'ră-fē) A test that evaluates the function of the bile ducts by injection of a contrast medium directly into the common bile duct (during gallbladder surgery) or through a T-tube (after gallbladder surgery or during radiologic testing) and taking an X-ray.

cholecystography (kō-lē-sis-tog'ra-fē) A gallbladder function test performed by X-ray after the patient ingests an oral contrast agent; used to detect gallstones and bile duct obstruction.

cholesterol (kō-les'tēr-ol) A fat-related substance that the body produces in the liver and obtains from dietary sources; needed in small amounts to carry out several vital functions. High levels of cholesterol in the blood increase the risk of heart and artery disease.

chordae tendineae (kōr'dē ten-din'ē-ē) Cord-like structures that attach the cusps of the heart valves to the papillary muscles in the ventricles.

choroid (kōr'oyd) The middle layer of the eye, which contains the iris, the ciliary body, and most of the eye's blood vessels.

chromosome (krō'mə-sōm') Thread-like structure composed of DNA.

chronic (kron'ik) Lasting a long time or recurring frequently, as in chronic osteoarthritis.

chronic obstructive pulmonary disease (COPD) (kron'ik ōb-strūk'tiv pul'mō-nar-ē di-zēz') A disease characterized by the presence of airflow obstruction as a result of chronic bronchitis or emphysema. It is typically progressive. Cigarette smoking is the leading cause.

chronological résumé (kron'ō-loj'ik'ēl res-yūm'ā) The type of résumé used by individuals who have job experience. Jobs are listed according to date, with the most recent listed first.

chylomicron (kī-lō-mī'kron) The least dense of the lipoproteins; it functions in lipid transportation.

chyme (kīm) The mixture of food and gastric juice.

chymotrypsin (kī-mō-trip'sin) A pancreatic enzyme that digests proteins.

cilia (sil'ēa) Hair-like projections from the outside of the cell membrane on some cell types.

ciliary body (sil'ē-ar-ē bod'ē) A wedge-shaped thickening in the middle layer of the eyeball that contains the muscles that control the shape of the lens.

circumduction (ser-kūm-dūk'shūn) Moving a body part in a circle; for example, tracing a circle with your arm.

cirrhosis (sīr-ō'sis) A long-lasting liver disease in which normal liver tissue is replaced with nonfunctioning scar tissue.

Civilian Health and Medical Program of the Veterans Administration See CHAMPVA.

civil law (sī'vīl law) Involves crimes against persons. A person can sue another person, business, or the government. Judgments often require a payment of money.

clarification (klar'i-fi-kā'shūn) Asking questions that provide an increased understanding of a problem.

clarity (klār'i-tē) Clearness in writing or stating a message.

class action lawsuit (klas ak'shūn law'sūt) A lawsuit in which one or more people sue a company or other legal entity that allegedly wronged all of them in the same way.

clavicle (klav'i-kēl) A slender, curved long bone that connects the sternum and the scapula; also called the collar bone.

clean-catch mid-stream urine specimen (klēn kach mid-strēm yūr'in spes'i-mēn) A type of urine specimen that requires special cleansing of the external genitalia to avoid contamination by organisms residing near the external opening of the urethra and is used to identify the number and types of pathogens present in urine; sometimes referred to as midvoid.

clearinghouse (klēr'ing-hows) A group that takes nonstandard medical billing software formats and translates them into the standard EDI formats.

cleavage (klēv'āj) The rapid rate of mitosis of a zygote immediately following fertilization.

CLIA '88 See **Clinical Laboratory Improvement Amendments of 1988**.

clinical diagnosis (klin'i-kāl dī-āg-nō'sis) A diagnosis based on the signs and symptoms of a disease or condition.

clinical drug trial (klin'i-kāl drūg trī'āl) An internationally recognized research protocol designed to evaluate the efficacy or safety of drugs and to produce scientifically valid results.

Clinical Laboratory Improvement Amendments of 1988 (CLIA '88) (klin'i-kāl la'bōr-ā-tōr'ē im-prūv'ment ā-mend'ments) A law enacted by Congress in 1988 that placed all laboratory facilities that conduct tests for diagnosing, preventing, or treating human disease or for assessing human health under federal regulations administered by the Health Care Financing Administration

(HCFA) and the Centers for Disease Control and Prevention (CDC).

clinical preceptor (klin'i-kāl prē'sep-tōr) The person at the clinical site who serves as an instructor, but is an employee of the site.

clitoris (klit'ōr-is) Located anterior to the urethral opening in females. It contains erectile tissue and is rich in sensory nerves.

clock speed (klōk spēd) A measurement of how many instructions per second that a CPU can process. Clock speed is measured in megahertz (MHz) or gigahertz (GHz).

closed file (klōzd fīl) A file for a patient who has died, has moved away, or for some other reason no longer consults the office for medical expertise.

closed posture (klōzd pōs'chūr) A position that conveys the feeling of not being totally receptive to what is being said; arms are often rigid or folded across the chest.

cluster scheduling (klūs'tēr sked'jūl-ing) The scheduling of similar appointments together at a certain time of the day or week.

CMA See **Certified Medical Assistant**.

CMS See **Centers for Medicare and Medicaid Services**.

CNS See **central nervous system**.

coagulation (kō-ag'yū-lā'shūn) The process by which a clot forms in blood.

coccus (kōk'ūs) A spherical, round, or ovoid bacterium.

coccyx (kōk'sīks) A small, triangular-shaped bone consisting of three to five fused vertebrae.

cochlea (kok'lē-ā) A spiral-shaped canal in the inner ear that contains the hearing receptors.

cochlear implant (kok'lē-ār im'plant) Amplification device surgically implanted with its stimulating electrodes inserted directly into the non-functioning cochlea.

code linkage (kōd līng'kīj) Analysis of the connection between diagnostic and procedural information in order to evaluate the medical necessity of the reported charges. This analysis is performed by insurance company representatives.

coding (kōd'ing) Putting an identifying mark or phrase on a document to ensure that it is placed in the correct file folder.

coinsurance (kō-in-shūr'āns) A fixed percentage of covered charges paid by the insured person after a deductible has been met.

colitis (kō-lī'tis) Inflammation of the colon.

colonoscopy (kō-lon-os'kō-pē) A procedure used to determine the cause of diarrhea, constipation, bleeding, or lower abdominal pain by inserting a scope through the anus to provide direct visualization of the large intestine.

colony (kol'ō-nē) A distinct group of microorganisms, visible with the naked eye, on the surface of a culture medium.

color family (kūl'ōr fam'ī-lē) A group of colors that share certain characteristics, such as warmth or coolness, allowing them to blend well together.

colposcopy (kol-pos'kō-pē) The examination of the vagina and cervix with an instrument called a colposcope to identify abnormal tissue, such as cancerous or precancerous cells.

combination code (kom'bi-nā'shūn kōd') An ICD code in which two diagnoses are included in one code.

combining vowel (kom'bīn-ing vow'ēl) A vowel (often an *o*) that is placed between a word root and suffix to ease pronunciation.

Commission on Accreditation of Allied Health Education Programs (CAA-HEP) (kō-mish'ūn ā-kred'i-tā'shūn al'id helth) A voluntary organization that accredits allied health education programs.

common bile duct (kōm'ōn bīl dūkt) Duct that carries bile to the duodenum. It is formed from the merger of the cystic and hepatic ducts.

compactible file (kōm-pakt'ābl fīl) File kept on rolling shelves that slide along permanent tracks in the floor and stored close together or stacked when not in use.

complements (kom'plē-měnts) Proteins, present in serum, that are involved in specific defenses.

complementary medicine (kom'plē-men'tār-ē med'i-sin) A type of medicine that is used with conventional medicine.

complete blood (cell) count (CBC) (kōm-plēt' blūd kownt) A combination of the following determinations: red blood cell indices and count, white blood cell count, hematocrit, hemoglobin, platelets, and differential blood count.

complete proteins (kōm-plēt' prō'tēnz) Proteins that contain all nine essential amino acids.

complex carbohydrate (kom'pleks kahrbō-hīdrāt) A long chain of sugar units; also known as a polysaccharide.

complex inheritance (kom'pleks in-her'i-tāns) The inheritance of traits determined by multiple genes.

compliance plan (kōm-plī'āns plan) A process for finding, correcting, and preventing illegal medical office practices.

complimentary closing (kom'plē-měnt-ārē klōz-ing) The closing remark of a business letter found two spaces below the last line of the body of the letter.

compound (kom'pound) A substance that is formed when two or more atoms of more than one element are chemically combined.

compound microscope (kom'pound mī'krō-skōp) A microscope that uses two lenses to magnify the image created by condensed light focused through the object being examined.

comprehension (kom'prē-hen'shūn) Knowledge or understanding of an object, a situation, an event, or a verbal statement.

computed tomography (kōm-pyū'tēd tō-mog'rā-fē) A radiographic examination that produces a three-dimensional, cross-sectional view of an area of the body; may be performed with or without a contrast medium.

concise (kon-sīs') Brevity; the use of no unnecessary words.

concurrent care (kōn-kūr'ēnt kār) Care being provided by more than one physician, such as with specialists.

concussion (kōn-kūsh'ūn) A jarring injury to the brain; the most common type of head injury.

conditioning (kōn-dish'ūn-ing) Preparing documents for filing by removing paper clips or other fasteners from documents and mending any tears prior to filing. Also known as inspecting.

conductive hearing loss (kon-dūktiv'hēr'ing laws) A type of hearing loss that occurs when sound waves cannot be conducted through the ear. Most types are temporary.

condyle (kon'dīl) Rounded articular surface on a bone.

cones (kōnz) Light-sensing nerve cells in the eye, at the posterior of the retina,

that are sensitive to color, provide sharp images, and function only in bright light.

conflict (kōn'flikt) An opposition of opinions or ideas.

conjunctiva (kōn'jūngk-tī'vā) The protective membrane that lines the eyelid and covers the anterior of the sclera, or the white of the eye.

conjunctivitis (kōn-jūngk'ti-vī'tis) A contagious infection of the conjunctiva caused by bacteria, viruses, and allergies. The symptoms may include discharge, red eyes, itching, and swollen eyelids; also commonly called pinkeye.

connective tissue (kō-nek'tiv tish'ū) A tissue type that is the framework of the body.

consent (kōn-sent') A voluntary agreement that a patient gives to allow a medically trained person the permission to touch, examine, and perform a treatment.

constructive criticism (kon'strūkt-iv krit'ī-sis'ūm) A type of critique aimed at giving an individual feedback about his or her performance in order to improve that performance.

consultation (kon'sūl-tā'shūn) Meeting of two or more physicians or surgeons to evaluate the nature and progress of disease in a particular patient and to establish diagnosis, prognosis, and/or therapy.

consumable (kōn-sum'ā-bēl) Able to be emptied or used up, as with supplies.

consumer education (kōn-sum'ēr ed'yū-kā'shūn) The process by which the average person learns to make informed decisions about goods and services, including healthcare.

contagious (kōn-tā'jūs) Having a disease that can easily be transmitted to others.

contaminated (kōn-tam'ī-nā-tēd) Soiled or stained, particularly through contact with potentially infectious substances; no longer clean or sterile.

continuing education (kōn-tin'yū-ing ed'yū-kā'shūn) Systematic professional learning experiences designed to augment knowledge and skills of healthcare professionals; education completed after the initial educational program; required for relicensure in some fields.

contract (kon'trakt) A voluntary agreement between two parties in which specific promises are made.

contraindication (kon'tră-in-dī-kă'shŭn) A symptom that renders use of a remedy or procedure inadvisable, usually because of risk.

contrast medium (kon'trast mē'dē-ŭm) A substance that makes internal organs denser and blocks the passage of X-rays to photographic film. Introducing a contrast medium into certain structures or areas of the body can provide a clear image of organs and tissues and highlight indications of how well they are functioning.

controlled substance (kōn-trōld'sŭb'stăns) A drug or drug product that is categorized as potentially dangerous and addictive and is strictly regulated by federal laws.

control sample (kōn-trōl sam'pĕl) A specimen that has a known value; used as a comparison for test results on a patient sample.

contusion (kōn-tŭ'zhŭn) A closed wound, or bruise.

conventional medicine (kōn-vĕn'zhŭn-ĕl med'i-sin) The usual practice of physicians and other allied health professionals, such as physical therapists, psychologists, medical assistants, and registered nurses. Also known as allopathy.

conventions (kōn-vĕn'zhŭnz) A list of abbreviations, punctuation, symbols, typefaces, and instructional notes appearing in the beginning of the ICD-9. The items provide guidelines for using the code set.

convolutions (kon-vō-lŭ'shŭnz) The ridges of brain matter between the sulci; also called gyri.

coordination of benefits (kō-ōr'di-nă'shŭn ben'ĕ-fits) A legal principle that limits payment by insurance companies to 100% of the cost of covered expenses.

copayment (kō'pă-mĕnt) A fixed or set amount paid for each healthcare or medical service; the remainder is paid by the health insurance plan. Also called a copay.

COPD See **chronic obstructive pulmonary disease**.

cornea (kōr'nĕ-ă) A transparent area on the front of the outer layer of the eye that acts as a window to let light into the eye.

coronary artery bypass graft (CABG) (kōr'ō-năr-ĕ ahr'tēr-ĕ bĭ'pās graft) A surgery performed to bypass a

blockage within a coronary artery with a vessel taken from another area.

coronary circulation (kōr'ō-năr-ĕ sĭr'kyŭ-lă'shŭn) The part of systemic circulation that provides the heart muscle with oxygen and nutrients and carries away waste products.

corporation (kōr'pō-ră'shŭn) A type of business group, such as a medical practice, that is established by law and managed by a board of directors.

corpus callosum (kōr'pŭs ka-lō'sŭm) A thick bundle of nerve fibers that connects the cerebral hemispheres.

corpus luteum (kōr'pŭs lŭ-tĕ-ŭm) A ruptured follicle cell in the ovary following ovulation.

cortex (kōr'teks) The outermost layer of the cerebrum.

cortisol (kōr'ti-sol) A steroid hormone that is released when a person is stressed. It decreases protein synthesis.

coryza (kō-rĭ'ză) Another name for an upper respiratory tract infection; the common cold.

costal (kos'tăl) Cartilage that attaches true ribs to the sternum.

counseling (kown'sĕl-ing) Provision of advice and instruction by a healthcare professional to patients.

counter check (kown'tĕr chek) A special bank check that allows a depositor to draw funds from his own account only, as when he has forgotten his checkbook.

courtesy title (kŭr'ti-sĕ tĭtl) A title used before a person's name, such as Dr., Mr., or Ms.

covered entity (kŭv'ĕrd en'ti-tĕ) Any organization that transmits health information in an electronic form that is related in any way with a HIPAA-covered business.

cover sheet (kŭv'ĕr shĕt) A form sent with a fax that provides details about the transmission.

Cowper's glands (kow'pĕrz glandz) Bulbourethral glands.

coxal (koks'-al) Pertaining to the bones of the pelvic girdle. The coxa is composed of the ilium, ischium, and pubis. (24)

CPT See *Current Procedural Terminology*.

CPU See **central processing unit**.

cranial (kră'nĕ-ăl) See **superior**.

cranial nerves (kră'nĕ-ăl nĕrvs) Peripheral nerves that originate from the brain.

crash cart (krăsh kărt) A rolling cart of emergency supplies and equipment.

creatine phosphate (krĕ'ă-tĕn fos'făt) A protein that stores extra phosphate groups.

credentialing (krĕ-den'shăl-ing) A formal review of the qualifications of a healthcare provider who has applied to participate in a healthcare system or plan.

credit (krĕd'ĭt) An extension of time to pay for services, which are provided on trust.

credit bureau (krĕd'ĭt būr-ō) A company that provides information about the creditworthiness of a person seeking credit.

cricoid cartilage (krĭ'koyd kahr'ti-lăj) A cartilage of the larynx that forms most of the posterior wall and a small part of the anterior wall.

crime (krĭm) An offense against the state committed or omitted in violation of public law.

criminal law (krim'i-năl law) Involves crimes against the state. When a state or federal law is violated, the government brings criminal charges against the alleged offender.

critical care (krit'i-kăl kār) Care provided to unstable, critically ill patients. Constant bedside attention is needed in order to code critical care.

critical thinking (krit'i-kăl thing'ing) The practice of considering all aspects of a situation when deciding what to believe or what to do.

cross-reference (kraws ref'rĕns) The notation within the ICD-9 of the word *see* after a main term in the index. The *see* reference means that the main term first checked is not correct. Another category must then be used.

cross-referenced (kraws ref'rĕns'd) Filed in two or more places, with each place noted in each file; the exact contents of the file may be duplicated, or a cross-reference form can be created, listing all the places to find the file.

cross-training (kraws trăn'ing) The acquisition of training in a variety of tasks and skills.

cryosurgery (krĭō-sŭr'jĕr-ĕ) The use of extreme cold to destroy unwanted tissue, such as skin lesions.

cryotherapy (krĭō-thăr'ă-pĕ) The application of cold to a patient's body for therapeutic reasons.

cryptorchidism (kript-ōr'ki-dizm) Congenital failure of the testes to descend into the scrotal sac.

crystal (kris'tăl) Naturally produced solid of definite form; commonly seen in urine

specimens, especially those permitted to cool.

cultural diversity (kŭl'chŭr-ăl

di-vēr'si-tē) The inevitable variety in customs, attitudes, practices, and behavior that exists among groups of people from different ethnic, racial, or national backgrounds who come into contact.

culture (kŭl'chŭr) In the sociologic sense, a pattern of assumptions, beliefs, and practices that shape the way people think and act.

To place a sample of a specimen in or on a substance that allows microorganisms to grow in order to identify the microorganisms present.

culture and sensitivity (C&S) (kŭl'chŭr

sen'si-tiv'i-tē) A procedure that involves culturing a specimen and then testing the isolated bacteria's susceptibility (sensitivity) to certain antibiotics to determine which antibiotics would be most effective in treating an infection.

culture medium (kŭl'chŭr mē'dē-ŭm) A substance containing all the nutrients a particular type of microorganism needs to grow.

Current Procedural Terminology (CPT)

(kŭr'rēnt prō-sē'jŭr-ăl tēr-mi-nol'ō-jē) A book with the most commonly used system of procedure codes. It is the HIPAA-required code set for physicians' procedures.

cursor (kŭrs'ōr) A blinking line or cube on a computer screen that shows where the next character that is keyed will appear.

Cushing's disease (kush'ingz dī-zēz')

A condition in which a person produces too much cortisol or has used too many steroid hormones. Some of the signs and symptoms include buffalo hump, obesity, a moon face, and abdominal stretch marks; also called hypercortisolism.

cuspid (kŭs'pidz) The sharpest teeth; they tear food.

customized (kŭs'tōm-īzd) Altering something to meet individual specifications such as when creating unique settings within an EHR software program to meet the needs of a specialty physician or medical office.

cyanosis (s'ă-nō'sis) A bluish color of skin that results when the supply of oxygen is low in the blood.

cycle billing (s'īkēl bil'ing) A system that sends invoices to groups of patients every

few days, spreading the work of billing all patients over the month while billing each patient only once.

cystic duct (sis'tik dŭkt) The duct from the gallbladder that merges with the hepatic duct to form the common bile duct.

cystitis (sis-tītis) Inflammation of the urinary bladder caused by infection.

cytokines (s'ītō-kīnz) Chemicals secreted by T lymphocytes in response to an antigen. Cytokines increase T- and B-cell production, kill cells that have antigens, and stimulate red bone marrow to produce more white blood cells.

cytokinesis (s'ītō-kī-nē'sis) Splitting of the cytoplasm during cell division.

cytoplasm (s'ītō-plazm) The watery intracellular substance that consists mostly of water, proteins, ions, and nutrients.

damages (dam'ij-iz) Money paid as compensation for violating legal rights.

database (dā'tă-bās) A collection of records created and stored on a computer.

dateline (dāt'līn) The line at the top of a letter that contains the month, day, and year.

debridement (dā-brēd-mont') The removal of debris or dead tissue from a wound to expose healthy tissue.

decibels (des'i-bēlz) Units for measuring the relative intensity of sounds on a scale from 0 to 130.

deductible (dē-dŭk'ti-bēl) A fixed dollar amount that must be paid by the insured before additional expenses are covered by an insurer.

deep (dēp) Anatomical term meaning closer to the inside of the body.

defamation (def'ē-mă'shŭn) Damaging a person's reputation by making public statements that are both false and malicious.

defecation reflex (def-ē-kă'shŭn rē'fleks') The relaxation of the anal sphincters so that feces can move through the anus in the process of elimination.

deflection (dē-flek'shŭn) A peak or valley on an electrocardiogram.

dehydration (dē-hī-dră'shŭn) The condition that results from a lack of adequate water in the body.

dementia (dē-men'shē-ă) The deterioration of mental faculties from organic disease of the brain.

demographic (dē-mog'ră-fik) Statistical data relating to the population and particular groups within it.

dendrite (dēn'drīt) A type of nerve fiber that is short and branches near the cell body. Its function is to receive information from the neuron.

deoxyhemoglobin (dē-oks'ē-hē'mō-glō-bin) A type of hemoglobin that is not carrying oxygen. It is darker red in color than hemoglobin.

dependent (dē-pen'dēnt) A person who depends on another person for financial support.

depolarization (dē-pō'lăr-i-ză'shŭn) The loss of polarity, or opposite charges inside and outside; the electrical impulse that initiates a chain reaction resulting in contraction.

depolarized (dē-pō'lăr-īzd) A state in which sodium ions flow to the inside of the cell membrane, making the outside less positive. Depolarization occurs when a neuron responds to stimuli such as heat, pressure, or chemicals.

depression (dē-presh'ŭn) The lowering of a body part.

dermatitis (dēr'mă-tītis) Inflammation of the skin.

dermatologist (dēr'mă-tol'ō-jist) A specialist who diagnoses and treats diseases of the skin, hair, and nails.

dermatome (dēr'mă-tōm) An area of skin innervated by a spinal nerve.

dermis (dēr'mis) The middle layer of the skin, which contains connective tissue, nerve endings, hair follicles, sweat glands, and oil glands.

descending colon (dē-send'ing

kō'lōn) The segment of the large intestine after the transverse colon that descends the left side of the abdominal cavity.

descending tracts (dē-send'ing

trakts) Tracts of the spinal cord that carry motor information from the brain to muscles and glands.

desired dose (D) (dez'ird dōs) The amount of medication the licensed practitioner has ordered the patient to take.

detrusor muscle (dē-trŭ'sōr mŭs'ēl)

A smooth muscle that contracts to push urine from the bladder into the urethra.

diabetes insipidus (dī-ă-bē'tēz in-sip'i-dŭs) The condition of excessive thirst and excessive urination related to hyposecretion of ADH so that water is not retained by the kidney.

diabetes mellitus (dī-ā-bē'tēz me-lī'tūs) Any of several related endocrine disorders characterized by an elevated level of glucose in the blood, caused by a deficiency of insulin or insulin resistance at the cellular level.

diagnosis (Dx) (dī-āg-nō'sis) The primary condition for which a patient is receiving care.

diagnosis code (dī-āg-nō'sis kōd) The way a diagnosis is communicated to the third-party payer on the healthcare claim.

diagnostic radiology (dī-āg-nōs'tik rā'dē-ol'ō-jē) The use of X-ray technology to determine the cause of a patient's symptoms.

diapedesis (dī-ā-pē-dē'sis) The squeezing of a cell through a blood vessel wall.

diaphoresis (dī-ā-fōr-ē'sis) Excessive sweating as a result of illness or injury.

diaphragm (dī-ā-fram) A muscle that separates the thoracic and abdominopelvic cavities.

diaphysis (dī-āf'i-sis) The shaft of a long bone.

diastolic pressure (dī-ā-stol'ik presh'ūr) The blood pressure measured when the heart relaxes.

diathermy (dī-ā-thēr-mē) A type of heat therapy in which a machine produces high-frequency electromagnetic waves that achieve deep heat penetration in muscle tissue.

diencephalon (dī-en-sef'ā-lon) A structure that includes the thalamus and the hypothalamus. It is located between the cerebral hemispheres and is superior to the brain stem.

dietary supplements (dī-ē-tār-ē sūp'lē-mēnts) Vitamins, minerals, herbals, and other substances taken by mouth without a prescription to promote health and well-being.

differential diagnosis (dīf'ēr-en'shāl dī-āg-nō'sis) The process of determining the correct diagnosis when two or more diagnoses are possible.

differently abled (dīf'ēr-ent'lē ā-bld) Having a condition that limits or changes a person's abilities and may require special accommodations.

diffusion (dī-fyū'zhūn) The movement of a substance from an area of high concentration to an area of low concentration.

digital examination (dij'i-tāl eg-zam'i-nā'shūn) Part of a physical examination in which the physician inserts one or two fingers of one hand into the opening of a body canal such as the vagina or the rectum; used to palpate canal and related structures.

digital subscriber line (DSL) (dij'i-tāl sūb-skribr līn) A type of modem that operates over telephone lines but uses a different frequency than a telephone, allowing a computer to access the Internet at the same time that a telephone is being used.

diluent (dīl'yū-ěnt) A liquid used to dissolve and dilute another substance, such as a drug.

disability insurance (dis'ā-bil'i-tē in-shūr'āns) Insurance that provides a monthly, prearranged payment to an individual who cannot work as the result of an injury or disability.

disaccharide (dī-sak'ā-rīd) A type of carbohydrate that is a simple sugar.

disbursement (dis-bērs'-mēnt) Any payment of funds made by the physician's office for goods and services.

disclaimer (dis-clām'ēr) A statement of denial of legal liability or that refutes the authenticity of a claim.

disclosure (dīs-klō'zhūr) The release of, the transfer of, the provision of access to, or the divulgence in any manner of patient information.

disclosure statement (dis-klō'zhūr stāt'mēnt) A written description of agreed terms of payment; also called a federal Truth in Lending Statement.

discrimination (dis-krim'i-nā'shūn) Unequal and unfair treatment.

disinfectant (dis-in-fek'tānt) A cleaning product applied to instruments and equipment to reduce or eliminate infectious organisms; not used on human tissue.

disinfection (dis-in-fek'shūn) Destruction of pathogenic microorganisms or their toxins or vectors by direct exposure to chemical or physical agents.

disk cleanup (dīsk klēn-up) A computer maintenance utility designed to free up disk space on computer users' hard drive.

disk defragmentation (dīsk dē-frag'mēnt-tā'shūn) A computer program designed to increase access speed by rearranging files stored on a disk to occupy contiguous storage locations, a technique commonly known as defragmenting.

dislocation (dis'lō-kā'shūn) The displacement of a bone end from a joint.

dispense (dis-pens') To distribute a drug, in a properly labeled container, to a patient who is to use it.

distal (dis'tāl) Anatomical term meaning farther away from a point of attachment or farther away from the trunk of the body.

distal convoluted tubule (dis'tāl kon'vō-lūt'ed tū'byūl) The last twisted section of the renal tubule; it is located after the loop of Henle. Several of these tubules merge together to form collecting ducts.

distribution (dis'tri-byū'shūn) The biochemical process of transporting a drug from its administration site in the body to its site of action.

diversity (di-vēr'si-tē) Differences among people in terms of identity, age, sex, race, physical ability, ethnicity, religious beliefs, values and mores, sexual orientation, and personality.

diverticula (dī-vēr-tik'yū-lā) Pouches or sacs opening from a tubular or saccular organ, such as the gut or bladder. Plural of *diverticulum*.

diverticulitis (dī-vēr-tik'yū-lī'tis) Inflammation of the diverticuli, which are abnormal dilations in the intestine.

diverticulosis (dī-vēr-tik'yū-lō'sis) Abnormal outpouchings or dilations of the intestine.

DNA (dē'ēn-ā') A nucleic acid that contains the genetic information of cells.

doctor of osteopathy (dok'tōr os'tē-op'ā-thē) A doctor who focuses on the musculoskeletal system and uses hands and eyes to identify and adjust structural problems, supporting the body's natural tendency toward health and self-healing.

doctrine of informed consent (dok'trin in-fōrmd' kōn-sent') The legal basis for informed consent, usually outlined in a state's medical practice act.

doctrine of professional discretion (dok'trin prō-fesh'i-nāl dis-krē'shūn) A principle under which a physician can exercise judgment as to whether to show patients who are being treated for mental or emotional conditions their records.

documentation (dok'yū-mēn-tā'shūn) The recording of information in a patient's medical record; includes detailed notes about each contact with the patient and about the treatment plan,

- patient progress, and treatment outcomes.
- dorsal (dōr'sāl)** See **posterior**.
- dorsal root (dōr'sāl rūt)** A portion of a spinal nerve that contains axons of sensory neurons only.
- dorsiflexion (dōr-si-flek'shūn)** Pointing the toes upward.
- dosage (dō'sāj)** The size, frequency, and number of doses.
- dose (dōs)** The amount of a drug given or taken at one time.
- dose on hand (H) (dōs hand)** The amount of medication in each unit of the drug.
- dot matrix printer (dōt mā'trīks prīn'ter)** An impact printer that creates characters by placing a series of tiny dots next to one another.
- double-booking system (dūb'ēl buk'-ing sis'tēm)** A system of scheduling in which two or more patients are booked for the same appointment slot, with the assumption that both patients will be seen by the doctor within the scheduled period.
- douche (dūsh)** Vaginal irrigation, which can be used to administer vaginal medication in liquid form.
- downcoding (down'kōd-ing)** The insurance carrier bases reimbursement on a code level lower than the one submitted by the provider.
- drainage catheter (drān'āj kath'ē-tēr)** A type of catheter used to withdraw fluids.
- dressings (drēs'ing)** A sterile material used to cover a surgical or other wound.
- dual coverage (d'yū-āl kŭv'ēr-āj)** Term used when a patient is covered by Medicare and Medicaid.
- dual-energy X-ray absorptiometry (DXA) (dū'āl en'ēr-jē x-rā āb-sōrp'shē-om'ē-trē)** A screening test that uses small doses of X-rays to determine the mineral density of a person's bones; also called *bone densitometry*.
- ductus arteriosus (dŭk'tūs ar-tēr'ē-ō'sus)** The connection in the fetus between the pulmonary trunk and the aorta.
- ductus venosus (duk'tūs vē-nō'sūs)** A blood vessel that allows most of the blood to bypass the liver in the fetus.
- duodenum (dū'ō-dē'nŭm)** The first section of the small intestine.
- durable item (dūr'ā-bēl ītem)** A piece of equipment that is used repeatedly, such as a telephone, computer, or examination table; contrast with *expendable item*.
- durable power of attorney (dūr'ā-bēl pow'ēr ā-tōr'nē)** A document naming the person who will make decisions regarding medical care on behalf of another person if that person becomes unable to do so.
- dwarfism (dwōrf'izm)** A condition in which too little growth hormone is produced, resulting in an abnormally small stature.
- dysmenorrhea (dis-men-ōr-ē'ā)** Severe menstrual cramps that limit daily activity.
- dysrhythmia (dis-ritih'mē-ā)** An irregularity in heart rhythm; also called *arrhythmia*.
- dyspnea (disp'-nēā)** Difficult or painful breathing.
- ear ossicles (ēr os'i-kēlz)** Three tiny bones called the malleus, the incus, and the stapes located in the middle ear cavity. They are the smallest bones of the body.
- eccrine gland (ek'rin glānd)** The most numerous type of sweat gland. Eccrine sweat glands produce a watery type of sweat and are activated primarily by heat.
- ECG** See **electrocardiogram**.
- echocardiography (ek'ō-kahr-dē-og'rā-fē)** A procedure that tests the structure and function of the heart through the use of reflected sound waves, or echoes.
- E code (ē kōd)** A type of code in the ICD-9. E codes identify the external causes of injuries and poisoning.
- ectoderm (ek'tō-derm)** The primary germ layer that gives rise to nervous tissue and some epithelial tissue.
- ectropion (ek-trō'pē-ŭn)** Eversion of the lower eyelid.
- eczema (ek'sē-mā)** Inflammatory condition of the skin.
- edema (ē-dē'mā)** An excessive buildup of fluid in body tissue.
- EDI** See **electronic data interchange**.
- editing (ed'i-ting)** The process of ensuring that a document is accurate, clear, and complete; free of grammatical errors; organized logically; and written in the appropriate style.
- effacement (e-fās'mēnt)** Thinning of the cervix in preparation for childbirth.
- effectors (e-fek'tōrz)** Muscles and glands that are stimulated by motor neurons in the peripheral nervous system.
- efferent arterioles (ef'ēr-ēnt ahr-tēr'ē-ōlz)** Structures that deliver blood to peritubular capillaries that are wrapped around the renal tubules of the nephron in the kidneys.
- efferent nerves (ef'ēr-ēnt nērvz)** Motor nerves that take information or impulses from the central nervous system to the peripheral nervous system to allow for the movement or action of a muscle or gland.
- efficacy (ef'i-kā-sē)** The therapeutic value of a procedure or therapy, such as a drug.
- efficiency (ē-fish'ēn-sē)** The ability to produce a desired result with the least effort, expense, and waste.
- EHR** See **electronic health records**.
- EIA** See **enzyme immunoassay**.
- elderly (el'dēr-lē)** Individuals over the age of 65.
- elective procedure (ē-lek'tiv prō-sē'jūr)** A medical procedure that is not required to sustain life but is requested for payment to the third-party payer by the patient or physician. Some elective procedures are paid for by third-party payers, whereas others are not.
- electrocardiogram (ECG) (ē-lek'trō-kahr'dē-ō-gram)** The tracing made by an electrocardiograph.
- electrocardiograph (ē-lek'trō-kahr'dē-ō-graf)** An instrument that measures and displays the waves of electrical impulses responsible for the cardiac cycle.
- electrocardiography (ē-lek'trō-kahr-dē-og'rā-fē)** The process by which a graphic pattern is created to reflect the electrical impulses generated by the heart as it pumps.
- electrocauterization (ē-lek'trō-kaw'tēr-ī-zā'shūn)** The use of a needle, probe, or loop heated by electric current to remove growths such as warts, to stop bleeding, and to control nosebleeds that either will not subside or continually recur.
- electrode (ē-lek'trōd)** Sensor that detects electrical activity.
- electroencephalography (ē-lek'trō-en-se-f'ā-log'rā-fē)** A procedure that records the electrical activity of the brain as a tracing called an electroencephalogram, or EEG, on a strip of graph paper.
- electrolytes (ē-lek'trō-līts)** Substances that carry electrical current through the movement of ions.
- electromyography (ē-lek'trō-mī-og'rā-fē)** A procedure in which needle electrodes are inserted into some of the

- skeletal muscles and a monitor records the nerve impulses and measures conduction time; used to detect neuromuscular disorders or nerve damage.
- electronic data interchange (EDI) (ě-lek-tron'ik dā'tā in'tēr-chānj)** Transmitting electronic medical insurance claims from providers to payers using the necessary information systems.
- electronic health records (EHR) (ě-lek-tron'ik helth rek'ördz)** Patient health records created and stored on a computer or other electronic storage device. Also known as *electronic medical records*.
- electronic mail (ě-lek-tron'ik māl)** A method of sending and receiving messages through a computer network; commonly known as e-mail.
- electronic media (ě-lek-tron'ik mē'dē-ă)** Any transmissions that are physically moved from one location to another through the use of magnetic tape, disk, compact disk media, or any other form of digital or electronic technology.
- electronic medical record (EMR) (ě-lek-tron'ik med'i-kāl rek'örd)** Patient medical record created and stored on a computer or other electronic storage device.
- electronic transaction record (ě-lek-tron'ik tranz-ak'shūn rek'örd)** The standardized codes and formats used for the exchange of medical data.
- elevation (el'ě-vā'shūn)** The raising of a body part.
- ELISA test** See **enzyme-linked immunosorbent assay test**.
- embolism (em'bō-lizm)** An obstruction in a blood vessel.
- embolus (em'bō-lūs)** A portion of a thrombus that breaks off and moves through the bloodstream.
- embryo (em'brē-ō)** A group of cells, called the *inner cell mass*, that develops from the blastocyst during the embryonic prenatal period to become the fetus.
- embryonic period (em-brē-on'ik pēr'ē-ōd)** The second through eighth weeks of pregnancy.
- E/M code (ě/ēm kōd)** Evaluation and management codes that are often considered the most important of all CPT codes. The E/M section guidelines explain how to code different levels of services.
- empathy (ěmpā-thē)** Identification with or sensitivity to another person's feelings and problems.
- emphysema (em'fi-sē'mā)** A chronic lung condition consisting of damage to the alveoli of the lungs. It is heavily associated with smoking, which causes stretching of the spaces between the alveoli and paralyzes the cilia of the respiratory system.
- employee handbook (em-ploy'ē hand'-buk)** A synopsis of human resources policies and procedures.
- employment contract (em-ploy'měnt kon'trakt)** A written agreement of employment terms between employer and employee that describes the employee's duties and the considerations (money, benefits, and so on) to be given by the employer in exchange.
- empyema (em'pī-ē'mā)** A collection of pus in the pleural cavity.
- EMR** See **electronic medical record**.
- enclosures (en-klō'zhūrz)** Materials that are included in the same envelope as the primary letter.
- encounter form (en-kown'tēr fōrm)** A form that combines the charges for services rendered, an invoice for payment or insurance copayment, and all the information for submitting an insurance claim; also known as a superbill.
- endocardium (en'dō-kahr'dē-ūm)** The innermost layer of the heart.
- enchondral (en'dō-kon'drāl)** A type of ossification in which bones start out as cartilage models.
- endocrine gland (en'dō-krin gland)** A gland that secretes its products directly into tissue, fluid, or blood.
- endocrinologist (en'dō-kri-nol'ō-jist)** A specialist who diagnoses and treats disorders of the endocrine system, which regulates many body functions by circulating hormones that are secreted by glands throughout the body.
- endoderm (ěndō-derm)** The primary germ layer that gives rise to epithelial tissues only.
- endogenous infection (en-doj'ě-nūs in-fek'shūn)** An infection in which an abnormality or a malfunction in routine body processes causes normally beneficial or harmless microorganisms to become pathogenic.
- endolymph (ěndō-limf)** A fluid in the inner ear. When this fluid moves, it activates hearing and equilibrium receptors.
- endometriosis (en'dō-mē-trē-ō'sis)** A condition in which tissues that make up the lining of the uterus grow outside the uterus.
- endometrium (en'dō-mē'trē-ūm)** The innermost layer of the uterus. It undergoes significant changes during the menstrual cycle.
- endomysium (en'dō-miz'ē-ūm)** A connective tissue covering that surrounds individual muscle cells.
- endoplasmic reticulum (en'dō-plas'mik rē-tik'yū-lūm)** The organelles of the endoplasmic reticulum are composed of both smooth and rough types. The rough type contains ribosomes on its surface. The smooth type has no ribosomes. Both types create a network of passageways throughout the cytoplasm.
- endorse (en-dōrs')** To sign or stamp the back of a check with the proper identification of the person or organization to whom the check is made out, to prevent the check from being cashed if it is stolen or lost.
- endorsement (en-dōrs'-měnt)** Signature on the back of a check with the terms for accepting the check as payment.
- endoscopy (en-dos'kō-pē)** Any procedure in which a scope is used to visually inspect a canal or cavity within the body.
- endosteum (en-dos'tē-ūm)** A membrane that lines the medullary cavity and the holes of spongy bone.
- engineered safety devices (en'jin-ērd sāl'tē dē-vīs')** Devices specifically designed to isolate or remove a hazard. These include needles with safety shields and self-shielding needles.
- entropion (en-trō'pē-on)** Inversion of the lower eyelid.
- enunciation (ě-nūn-sī-ā'shūn)** Clear and distinct speaking.
- enuresis (en-yūr-ē'sis)** Bed wetting.
- enzyme immunoassay (EIA) (ěnzīm im'yū-nō-as'ā)** The detection of substances by immunologic methods. This method involves an antigen, an antibody specific for the antigen, and a second antibody conjugated to an enzyme.
- enzyme-linked immunosorbent assay (ELISA) test (ěnzīm-līngkt im'yū-nō-sōr'bent ās'ā tēst)** A blood test that confirms the presence of antibodies developed by the body's immune system in response to an initial HIV infection.
- EOB** See **explanation of benefits**.

- eosinophil (ē-ō-sin'ō-fil)** A type of granular leukocyte that captures invading bacteria and antigen-antibody complexes through phagocytosis.
- epicardium (ep-i-kar'dē-ŭm)** The outermost layer of the wall of the heart. Also known as the **visceral pericardium**.
- epidermis (ep'i-dēr'mis)** The most superficial layer of the skin.
- epididymis (ep-i-did'i-mis)** An elongated structure attached to the back of the testes and in which sperm cells mature.
- epididymitis (ep-i-did-i-mī'tis)** Inflammation of an **epididymis**. Most cases result from infection.
- epiglottic cartilage (ep-i-glot'ik kahr'ti-lāj)** A cartilage of the larynx that forms the framework of the epiglottis.
- epiglottis (ep-i-glot'is)** The flap-like structure that closes off the larynx during swallowing.
- epilepsy (ep'i-lep'sē)** A condition that occurs when parts of the brain receive a burst of electrical signals that disrupt normal brain function; also called seizures.
- epimysium (ep'i-mis'ē-ŭm)** A thin covering that is just deep to the fascia of a muscle. It surrounds the entire muscle.
- epinephrine (ep'i-nef'rin)** An injectable medication used to treat anaphylaxis by causing vasoconstriction to increase blood pressure. Also, a hormone secreted from the adrenal glands. It increases heart rate, breathing rate, and blood pressure.
- epiphyseal disk (ep-i-fiz'ē-āl dīsk)** A plate of cartilage between the **epiphysis** and the **diaphysis**.
- epiphysis (e-pif'i-sis)** The expanded end of a long bone.
- episiotomy (e-piz'ē-ot'ō-mē)** A surgical incision of the female perineum to enlarge the vaginal opening for delivery.
- epistaxis (ēp'i-stak'sis)** Nosebleed.
- epithelial tissue (ep'i-thē'lē-āl tish'ū)** A tissue type that lines the tubes, hollow organs, and cavities of the body.
- e-prescribing (ē-prē-skrīb'ing)** Prescriptions are entered electronically and transmitted directly to the pharmacy.
- erectile tissue (ē-rek'til tish'ū)** A highly specialized tissue located in the shaft of the penis. It fills with blood to achieve an erection.
- ergonomics (ēr'gō-nom'iks)** The science of workplace, tools, and equipment designed to reduce worker discomfort, strain, and fatigue and to prevent work-related injuries.
- erythema (er-i-thē'mā)** Redness of the skin.
- erythroblastosis fetalis (ē-rith'rō-blastō'sis fē-tā'lis)** A serious anemia that develops in a fetus with Rh-positive blood as a result of antibodies in an Rh-negative mother's body.
- erythrocyte (ē-rith'rō-sīt)** Red blood cell.
- erythrocyte sedimentation rate (ESR) (ē-rith'rō-sīt sed'i-mēn-tā'shŭn rāt)** The rate at which red blood cells, the heaviest blood component, settle to the bottom of a blood sample.
- erythropoietin (ē-rith'rō-poy'ē-tin)** A hormone secreted by the kidney and responsible for regulating the production of red blood cells.
- esophageal hiatus (ē-sof'ā-jē'āl hī-ā'tūs)** Hole in the diaphragm through which the esophagus passes.
- ESR** See erythrocyte sedimentation rate.
- established patient (es-tab'lisht pā'shēnt)** A patient who has seen the physician within the past 3 years. This determination is important when using E/M codes.
- estrogen (es'trō-jen)** A female sex hormone; when produced during ovulation, estrogen causes a buildup of the lining of the uterus (womb) to prepare it for a possible pregnancy.
- ethics (ēth'iks)** General principles of right and wrong, as opposed to requirements of law.
- ethmoid (ēth'moyd)** Bones located between the sphenoid and nasal bone that form part of the floor of the cranium.
- ethylenediaminetetraacetic acid (EDTA) (eth'i-lēn-dī'ā-mēn-tet'rā-ā-sē'tik as'id)** A chelating agent and anticoagulant; added to blood specimens for hematologic and other tests.
- etiologic agent (ē'tē-ə-lōj'ik ā'jənt)** A living microorganism or its toxin that may cause human disease.
- etiology (ē'tē-ol'ō-jē)** The science and study of the causes of disease and their mode of operation.
- etiquette (ēt'i-ke't')** Good manners.
- eustachian tube (yū-stā'-shē-an tūb)** An opening in the middle ear, leading to the back of the throat, that helps equalize air pressure on both sides of the eardrum.
- eversion (ē-ver'zhŭn)** Turning the sole of the foot laterally.
- exclusion (eks-klŭ'zhŭn)** An expense that is not covered by a particular insurance policy, such as an eye examination or dental care.
- excretion (eks-krē'shŭn)** The elimination of waste by a discharge; in drug metabolism, the manner in which a drug is eliminated from the body.
- exocrine gland (ek'sō-krin gland)** A gland that secretes its product into a duct.
- exogenous infection (eks-ōj'ē-nŭs in-fek'shŭn)** An infection that is caused by the introduction of a pathogen from outside the body.
- exophthalmos (eks'of-thal'mos)** Bulging of the eyeballs, often related to hyperthyroidism.
- expendable item (eks-pen'dā-bēl ītem)** An item that is used and must then be restocked; also known collectively as supplies. Contrast with *durable item*.
- expiration (eks'pir-ā'shŭn)** The process of breathing out; also called exhalation.
- explanation of benefits (EOB) (eks'plā-nā'shŭn ben'ē-fits)** Information that explains the medical claim in detail; also called **remittance advice (RA)**.
- explanation of payment (EOP) (eks'plā-nā'shŭn pā'mēnt)** Document sent by an insurance carrier when payment is made describing the terms of the payments. Also known as **explanation of benefits (EOB)** or **remittance advice (RA)**.
- exposure control plan (eks-pō'zhŭr kōn-trōl' plan)** A written document of practices and procedures, required equipment, and facilities designed to minimize employee exposure to infectious agents or biohazardous materials.
- expressed contract (eks-prest' kon'trakt)** A contract clearly stated in written or spoken words.
- extension (eks-ten'shŭn)** An unbending or straightening movement of the two elements of a jointed body part.
- external auditory canal (eks-tēr'nāl aw'di-tōr-ē kā-nāl')** Canal that carries sound waves to the tympanic membrane; commonly called the ear canal.
- extrinsic eye muscles (eks-trin'zīk ī mŭs'ēlz)** The skeletal muscles that move the eyeball.
- face page (fās pāj')** A screen that provides an overview or "snapshot" of the patient demographic information in an EHR system.

face sheet (fās shēt) A screen that provides an overview or “snapshot” of the patient demographic information in an EHR system.

facsimile machine (fak-si’milē mā-shēn’) A piece of office equipment used to send a facsimile, or fax, over telephone lines from one modem to another; more commonly called a fax machine.

factual teaching (fak’chū-āl tēch’ing) Method of teaching that provides the patient with details of the information that is being taught.

facultative (fak’ül-tā-tiv) Able to adapt to different conditions; in microbiology, able to grow in environments either with or without oxygen.

Fahrenheit (far’ēn-hīt) One of two common scales used for measuring temperature; measured in degrees Fahrenheit, or °F.

fallopian tubes (fā-lō’pē-ān tūbz) Tubes that extend from the uterus on each side and that open near an ovary.

family practitioner (fām-i-lē prāk-tish’i-ner) A physician who does not specialize in a branch of medicine but treats all types and ages of patients; also called a general practitioner.

fascia (fash’e-ā) A structure that covers entire skeletal muscles and separates them from each other.

fascicle (fas’i-kēl) Sections of a muscle divided by connective tissue called perimysium.

febrile (feb’ril) Having a body temperature above one’s normal range.

fecal occult blood test (FOBT) (fē’kāl ō-kūlt’ blūd test) A test to find hidden blood in the stool.

feces (fē’sēz) Material found in the large intestine and made from leftover chyme. Feces are eventually eliminated through the anus.

Federal Insurance Contributions Act (FICA) (fed’ēr-āl in-shūr’āns kon’tri-byū-shunz akt) A law that requires employers to deduct a certain amount from each employee’s paycheck to fund Social Security and Medicare.

Federal Unemployment Tax Act (FUTA) (fēd’ēr-al em-ploy’mēnt taks akt) This act requires employers to pay a percentage of each employee’s income up to a certain dollar amount.

feedback (fēd’bāk) Verbal and nonverbal evidence that a message was received and understood.

feedback loop (fēd’bāk lūp) A mechanism to control hormone levels. The two types are positive and negative feedback loops.

fee-for-service (fē sēr’vis) A major type of health plan. It repays policyholders for the costs of healthcare that are due to illness and accidents.

fee schedule (fē sked’jūl) A list of the costs of common services and procedures performed by a physician.

felony (fel’ōnē) A serious crime, such as murder or rape, that is punishable by imprisonment. In certain crimes, a felony is punishable by death.

femoral (fem’ō-rāl) Relating to the femur or thigh.

femur (fē’mūr) The bone in the upper leg; commonly called the thigh bone.

fenestrated drape (fen’ēs-trāt-ēd drāp) A drape that has a round or slit-like opening that provides access to the surgical site.

fertilization (fēr’til-i-zā’shūn) The process in which an egg unites with a sperm.

fetal period (fē’tāl pēr’ē-ōd) A period that begins at week nine of pregnancy and continues through delivery of the offspring.

fetus (fē’tūs) The product of conception from the end of the eighth week to the moment of birth.

fiber (fībēr) The tough, stringy part of vegetables and grains, which is not absorbed by the body but aids in a variety of bodily functions.

fibrinogen (fī-brin’ō-jen) A protein found in plasma that is important for blood clotting.

fibroid (fībroyd) A benign tumor in the uterus composed of fibrous tissue.

fibromyalgia (fī-brō-mī-al’jē-ā) A condition that exhibits chronic pain primarily in joints, muscles, and tendons.

fibula (fīb’yū-lā) The lateral bone of the lower leg.

file guide (fīl gīd) A heavy cardboard or plastic insert used to identify a group of file folders in a file drawer.

filtration (fīl-trā’shūn) A process that separates substances into solutions by forcing them across a membrane.

fimbriae (fī’m-brē-ē) Fringe-like structures that border the entrances of the fallopian tubes.

firewall (fīr’wawl) A system that protects a computer network from unauthorized

access by users on its own network or another network such as the Internet.

first morning urine specimen (first mōr’ning yūr’in spes’i-mēn)

A urine specimen that is collected after a night’s sleep; contains greater concentrations of substances that collect over time than specimens taken during the day.

fixative (fik’sā-tiv) A solution sprayed on a slide immediately after the specimen is applied. It is used to preserve and hold the cells in place until a microscopic examination is performed.

flaccid (fla’sid) Weak, soft; not erect.

flagellum (flā-jel’ūm) The “tail-like” structure on some cell membranes that provides cell movement.

flexion (flek’shūn) A bending movement of the two elements of a jointed body part.

floater (flōt’ēr) A nonsterile assistant who is free to move about the room during surgery and attend to unsterile needs.

fluidotherapy (flū’id-ō-thār’ā-pē)

A technique for stimulating healing, particularly in the hands and feet, by placing the affected body part in a container of glass beads that are heated and agitated with hot air.

follicle (fol’i-kēl) An accessory organ of the skin that is found in the dermis and the sites at which hairs emerge.

follicle-stimulating hormone (FSH) (fol’i-kēl stim’yū-lāt-ing hōr’mōn)

A hormone that in females stimulates the production of estrogen by the ovaries; in males, it stimulates sperm production.

follicular cells (fō-lik’yū-lār selz) Small cells contained in the primordial follicle along with a large cell called a primary oocyte.

folliculitis (fō-lik-yū-lī’tis) Inflammation of the hair follicle.

fomite (fō’mīt) An inanimate object, such as clothing, body fluids, water, or food, that may be contaminated with infectious organisms and thus transmit disease.

fontanels (fon’tā-nelz’) Soft spots in an infant’s skull that consist of tough membranes that connect to incompletely developed bone.

food exchange (fūd eks-chānj’) A unit of food in a particular food category that provides the same amounts of protein,

fat, and carbohydrates as all other units of food in that category.

foramen magnum (fōr-ā'mēn mag'nūm) The large hole in the occipital bone that allows the brain to connect to the spinal cord.

foramen ovale (fōr-ā'mēn ō-va'lē) A hole in the fetal heart between the right atrium and the left atrium.

forced vital capacity (FVC) (fōrst vī'tāl kă-pas'i-tē) The greatest volume of air that a person is able to expel when performing rapid, forced expiration.

formalin (fōr'mă-lin) A dilute solution of formaldehyde used to preserve biological specimens.

formed elements (fōrmd el'ē-mēnts) Red blood cells, white blood cells, and platelets; compose 45% of blood volume.

Form I-9 A federal form for verifying that an employee is a US citizen, a legally admitted alien, or an alien authorized to work in the United States.

formula method (fōrm'yū-lă meth'ōd) A basic formula to calculate dosage. $D/H \times Q$, where D: desired dose, H: dose on hand, Q: quantity of the dose.

formulary (fōrm'yū-lar-ē) An insurance plan's list of approved prescription medications.

Form W-2 The tax form that an employer must send to an employee and the IRS at the end of the year. It reports an employee's annual wages and the amount of taxes withheld from his or her paycheck.

Form W-4 A tax form completed by an employee to indicate his or her tax situation, such as exemptions and status, to the employer.

fracture (frak'shūr) Any break in a bone.

fraud (frawd) An act of deception that is used to take advantage of another person or entity.

frequency (frē'kwēn-sē) The number of complete fluctuations of energy per second in the form of waves.

frontal (frōn'tāl) Anatomical term that refers to the plane that divides the body into anterior and posterior portions. Also called coronal.

FSH See **follicle-stimulating hormone**.

fulgurated (ful'gūr-āt-ed) The use of heat or laser to burn or destroy tissue.

full-block letter style (ful' blok let'ēr stīl) A letter format in which all lines begin flush left; also called block style.

functional résumé (fūngk'shūn-āl rez'ūm-ā) A résumé that highlights specialty areas of a person's accomplishments and strengths.

fundus (fun'dūs) The upper, domed portion of an organ.

fungus (fūng'gūs) A eukaryotic organism that has a rigid cell wall at some stage in the life cycle.

FUTA See **Federal Unemployment Tax Act**.

FVC See **forced vital capacity**.

gait (gāt) The way a person walks, consisting of two phases: stance and swing.

ganglia (gang'glē-ā) Collections of neuron cell bodies outside the central nervous system.

gastric juice (gās'trīk jūs) Secretions from the stomach lining that begin the process of digesting protein.

gastritis (gă-strī'tīs) Inflammation of the stomach lining.

gastroenterologist (găs'trō-ēn-ter-ol'ō-jist) A specialist who diagnoses and treats disorders of the entire gastrointestinal tract, including the stomach, intestines, and associated digestive organs.

gastroesophageal reflux disease (GERD) (gas'trō-ē-sof'ā-jē'āl rē'flūks di-zēz) A condition that occurs when stomach acids are pushed into the esophagus and cause heartburn.

gene (jēn) A segment of DNA that determines a body trait.

general duty clause (jen'ēr-āl dū'tē klawz) An OSHA clause that requires an employer to maintain a workplace free from hazards that are recognized as likely to cause death or serious injury.

general physical examination (jen'ēr-āl fiz'i-kāl eg-zam'i-nā'shūn) An examination performed by a physician to confirm a patient's health or to diagnose a medical problem.

generic name (jē-ner'ik nām) A drug's official name.

geriatrician (jer'ē-at'-trish'ān) A specialist who cares for elderly individuals, usually those over the age of 65.

gerontologist (jer'ōn-tol'ō-jist) A specialist who studies the aging process.

GH See **growth hormone**.

gigantism (jī-gan'tizm) A condition in which too much growth hormone is produced in childhood, resulting in an abnormally increased stature.

glans penis (glanz pē'nīs) A cone-shaped structure at the end of the penis.

glaucoma (glaw-kō'mă) A condition in which too much pressure is created in the eye by excessive aqueous humor. This excess pressure can lead to permanent damage of the optic nerves, resulting in blindness.

Globally Harmonized System of Classification and Labeling of Chemicals (GHS) (glō'băl-lē har'-mōn-izd sis'tēm klas'i-fi-kă'shūn lă'bēl-ing kem'i-kălz) A system for standardizing the classification and labeling of chemicals developed by the United Nations as a guide for regulatory systems around the world. In the United States, OSHA's Hazard Communication Standard is now aligned with the GHS.

global period (glō'băl pēr'ē-ōd) The period of time that is covered for follow-up care of a procedure or surgical service.

globulins (glob'yū-linz) Plasma proteins that transport lipids and some vitamins.

glomerular filtrate (glō-mer'yū-lăr fil'trāt) The fluid remaining in the glomerular capsule after glomerular filtration.

glomerular filtration (glō-mer'yū-lăr fil'trā-shūn) The process by which urine forms in the kidneys as blood moves through a tight ball of capillaries called the glomerulus.

glomerulonephritis (glō-mer'yū-lō-nē-frī'tīs) An inflammation of the glomeruli of the kidney.

glomerulus (glō-mer'yū-lūs) A group of capillaries in the renal corpuscle.

glottis (glot'is) The opening between the vocal cords.

glucagon (glū'kă-gon) A hormone that increases glucose concentrations in the bloodstream and slows down protein synthesis.

gluten (glū'tēn) The insoluble protein (prolamines) constituent of wheat and other grains; a mixture of gliadin, glutenin, and other proteins; believed to be an agent in celiac disease.

glycogen (glī'kō-jen) An excess of glucose that is stored in the liver and in skeletal muscle.

glycosuria (glī'kō-syūr'ē-ă) The presence of significant levels of glucose in the urine.

goiter (goy'tēr) Enlargement of the thyroid gland, which causes swelling of the

- neck, often related to iodine insufficiency in the diet.
- Golgi apparatus** (gol'jē ap'ā-rat'ūs) The cell's Golgi apparatus synthesizes carbohydrates and appears to prepare and store secretions for discharge from the cell.
- gonadotropin-releasing hormone (GnRH)** (gō-nad'ō-trō'pin-rē-lēs'ing hōr'mōn) Hormone that stimulates the anterior pituitary gland to release follicle-stimulating hormone (FSH).
- gonads** (gō'nādz) The reproductive organs; namely, in women the ovaries, and in men the testes.
- goniometer** (gō'nē-om'ē-tēr) A protractor device that measures range of motion.
- gout** (gowt) A medical condition characterized by an elevated uric acid level and recurrent acute arthritis.
- G-protein** (jē-prō'tēn) A substance that causes enzymes in the cell to activate following the activation of the hormone-receptor complex in the cell membrane.
- Gram-negative** (gram' nēg'ā-tīv) Referring to bacteria that lose their purple color when a decolorizer has been added during a Gram stain.
- Gram-positive** (gram' pōz'ī-tīv) Referring to bacteria that retain their purple color after a decolorizer has been added during a Gram stain.
- Gram stain** (gram stān) A method of staining that differentiates bacteria according to the chemical composition of their cell walls.
- granular leukocyte** (gran'yū-lār lū'kō-sīt) A type of leukocyte (white blood cell) with a segmented nucleus and granulated cytoplasm; also known as a polymorphonuclear leukocyte.
- granulocyte** (gran'yū-lō-sīt) See **granular leukocyte**.
- Graves' disease** (grāvz dī-zēz') A disorder in which a person develops antibodies that attack the thyroid gland.
- gray matter** (grā māt'ər) The inner tissue of the brain and the spinal cord that is darker in color than white matter. It contains all the bodies and dendrites of nerve cells.
- grievance process** (grē-vāns pros'es) A mediation process through the human resources department utilized when an employee or employees feel they are treated unjustly.
- gross earnings** (grōs ěrn'ingz) The total amount an employee earns before deductions.
- group practice** (grūp prak'tis) A medical management system in which a group of three or more licensed physicians share their collective income, expenses, facilities, equipment, records, and personnel.
- growth chart** (grōth chahrt) A chart consisting of percentile curves that are used to determine a child's growth in relation to average rates.
- growth hormone (GH)** (grōth hōr'mōn') A hormone that stimulates an increase in the size of the muscles and bones of the body.
- growth plate** (grōth plāt) A shaft of cartilage between the epiphysis and the diaphysis; also known as the *epiphyseal disk*.
- guarantor** (gar'ān-tōr) The patient, caregiver, or entity responsible for payment of the healthcare bill.
- gustatory cortex** (gūs'tā-tōr-ē kōr'teks) An area of the brain that is responsible for interpreting taste sensations by integrating information from the taste cells with other information to provide a more complete interpretation.
- gustatory receptors** (gūs'tā-tōr-ē rē-sep'tōrz) Taste receptors that are found on taste buds.
- gynecologist** (gīnē-kol'ō-jist) A specialist who performs routine physical care and examinations of the female reproductive system.
- gyri** (jīrī) The ridges of brain matter between the sulci; also called **convolutions**.
- hairy leukoplakia** (hār'ē lū'kō-plā'kē-ā) A white lesion on the tongue associated with AIDS.
- haptens** (hap'tēn) Foreign substances in the body too small to start an immune response by themselves.
- hard copy** (hahrd kōp'ē) A readable paper copy or printout of information.
- hard skills** (hahrd skilz) Specific technical and operational proficiencies.
- hardware** (hahrd'wār) The physical components of a computer system, including the monitor, keyboard, and printer.
- Hazard Communication Standard (HCS)** (haz'ārd kō-myūn'i-kā'shūn stan'dārd) OSHA's standard for worker safety when working with hazardous chemicals. In 2012, the standard was updated to align with the Globally
- Harmonized System of Classification and Labeling of Chemicals (GHS).
- hazard label** (haz'ārd lā'bēl) A shortened version of the Safety Data Sheet; permanently affixed to a hazardous substance container.
- HCG** See **human chorionic gonadotropin**.
- HCPCS** See **Healthcare Common Procedure Coding System**.
- HCPCS Level II codes** (hik-piks lēv'ēl tū kōdz) Codes that cover many supplies such as sterile trays, drugs, and durable medical equipment; also referred to as national codes. They also cover services and procedures not included in the CPT.
- healthcare-associated infections (HAI)** (helth kār ā-sō'sē-āt-ed in-fek'shūns) Infections acquired by a patient in a healthcare facility.
- Healthcare Common Procedure Coding System (HCPCS)** (helth'kār kom'ōn prō-sē'jūr kōd'ing sis'tēm) A coding system developed by the Centers for Medicare and Medicaid Services that is used in coding services for Medicare patients.
- health fraud** (helth frawd) A deception or trickery related to health prevention or care for profit.
- Health Insurance Portability and Accountability Act** See **HIPAA**.
- Health Information Technology for Economics and Clinical Health** See **HITECH**.
- health maintenance organization (HMO)** (helth mān'tēn-āns ōr'gān-ī-zā'shūn) A healthcare organization that provides specific services to individuals and their dependents who are enrolled in the plan. Doctors who enroll in an HMO agree to provide certain services in exchange for a prepaid fee.
- helper T-cells** (hel'pēr selz) White blood cells that are a key component of the body's immune system and that work in coordination with other white blood cells to combat infection.
- hematemesis** (hē'-mā-tem'ē-sis) The vomiting of blood.
- hematocrit (Hct)** (hē-mat'ō-krit) The percentage of the volume of a sample made up of red blood cells after the sample has been spun in a centrifuge.
- hematology** (hē'mā-tol'ō-jē) The study of blood.
- hematoma** (hē'mā-tō'mā) A swelling caused by blood under the skin.

hematopoiesis (hě'mă-tō-poy-ě'sis) The process of new blood cell formation in the red bone marrow of cancellous bone.

hematuria (hě'mă-tyūr-ě-ă) The presence of blood in the urine.

hemocytoblast (hě'mō-sī'tō-blast) Cells of the red bone marrow that produce most red blood cells.

hemoglobin (Hgb) (hě'mō-glō'bin) A protein that contains iron and bonds with and carries oxygen to cells; the main component of erythrocytes.

hemoglobinuria (hě'mō-glō'bi-nyūr-ě-ă) The presence of free hemoglobin in the urine; a rare condition caused by transfusion reactions, malaria, drug reactions, snake bites, or severe burns.

hemolysis (hě-mol'ī-sis) The rupturing of red blood cells, which releases hemoglobin.

hemolytic anemias (hě'mō-lit'ik ă-ně'mē-ăz) Types of anemia that cause red blood cells to be destroyed faster than they can be made.

hemoptysis (hě-mop'ti-sis) The spitting up of blood from the respiratory tract.

hemorrhoids (hem'ōr-oydz) Varicose veins of the rectum or anus.

hemostasis (hě'mō-stā'sis) The stoppage of bleeding.

hemothorax (hě'mō-thōr'aks) Blood collection in the pleural cavity, causing collapse of the lung.

hepatic duct (hě-pat'ik dükt) A duct that leaves the liver carrying bile and merges with the cystic duct to form the common bile duct.

hepatic lobule (hě-pat'ik lob'yūl) Smaller division within the lobes of the liver.

hepatic portal system (hě-pat'ik pōr'tāl sis'tēm) The collection of veins carrying blood to the liver.

hepatic portal vein (hě-pat'ik pōr'tāl vān) A blood vessel that carries blood from the other digestive organs to the hepatic lobules.

hepatitis (hep'ă-tītis) Inflammation of the liver usually caused by viruses or toxins.

hepatocytes (hep'ă-tō-sītz) The cells within the lobules of the liver. Hepatocytes process nutrients in the blood and make bile.

hernia (hěr'nē-ă) The protrusion of an organ through the wall that usually contains it, such as a hiatal or inguinal hernia.

herpes simplex (her'pēz sīm'plēks) A medical condition characterized by an eruption of one or more groups of vesicles on the lips or genitalia.

herpes zoster (her'pēz zos'ter) A medical condition characterized by an eruption of a group of vesicles on one side of the body following a nerve root.

hierarchy (hī'ēr-ahr-kē) A term that pertains to Abraham Maslow's hierarchy of needs. This hierarchy states that human beings are motivated by unsatisfied needs and that certain lower needs must be satisfied before higher needs can be met.

hilum (hī'lūm) The indented side of a lymph node. Also, the entrance of the renal sinus that contains the renal artery, renal vein, and ureter.

HIPAA (Health Insurance Portability and Accountability Act) (hīp-uh) A set of regulations whose goals include the following: (1) improving the portability and continuity of healthcare coverage in group and individual markets; (2) combating waste, fraud, and abuse in healthcare insurance and healthcare delivery; (3) promoting the use of a medical savings account; (4) improving access to long-term care services and coverage; and (5) simplifying the administration of health insurance.

HITECH (Health Information Technology for Economics and Clinical Health) (hī-tek') The expansion of HIPAA coverage through increased regulations and enforcement penalties related to EHR and practice management systems.

HIV See **human immunodeficiency virus**.

HMO See **health maintenance organization**.

Holter monitor (hōl'tēr mon'i-tōr) An electrocardiography device that includes a microchip or a small cassette recorder worn around a patient's waist or on a shoulder strap to record the heart's electrical activity.

homeopathic medicine (hō-mē-ō-pāth'ik med'i-sin) A system of medicine that uses remedies in an attempt to stimulate the body to recover itself.

homeostasis (hō'mē-ō-stā'sis) A balanced, stable state within the body.

homologous chromosomes (hō-mol'ō-gūs krō'mō-sōmz) Members in each pair of chromosomes.

hormone (hōr'mōn') A chemical secreted by a cell that affects the functions of other cells.

hospice (hōs'pīs) Volunteers who work with terminally ill patients and their families.

household system (hows'hōld sis'tēm) A system of measurement that includes drops, teaspoons, tablespoons, ounces, cups, pints, quarts, and gallons.

human chorionic gonadotropin (HCG) (hyū'măn kōr'ē-on'ik gō-nad'ō-trō'pin) A hormone secreted by cells of the embryo after implantation. It maintains the corpus luteum in the ovary so that it will continue to secrete estrogen and progesterone.

human immunodeficiency virus (HIV) (hyū'măn im'yū-nō-dě-fish'ēn-sē vī'rūs) A retrovirus that gradually destroys the body's immune system and causes AIDS.

humerus (hyū'mēr-ūs) The bone of the upper arm.

humors (hyū'mōrz) Fluids of the body.

hydrotherapy (hī'drō-thār'ă-pē) The therapeutic use of water to treat physical problems.

hydrothorax (hī'drō-thōr'aks) Fluid collection in the pleural cavity causing collapse of the lung.

hyoid (hī'ōid) The bone that anchors the tongue.

hyperextension (hī'pēr-eks-ten'shūn) Extension of a body part past the normal anatomical position.

hyperglycemia (hī'pēr-glī-sē'mē-ă) High blood sugar.

hyperopia (hī'pēr-ō'pē-ă) A condition that occurs when light entering the eye is focused behind the retina; commonly called farsightedness.

hyperpnea (hī'pērp-nē'ă) Abnormally deep, rapid breathing.

hyperpyrexia (hī'pēr-pī-rek'sē-ă) An exceptionally high fever.

hyperreflexia (hī'pēr-rē-flek'sē-ă) Reflexes that are stronger than normal reflexes.

hypertension (hī'pēr-ten'shūn) High blood pressure.

hyperventilation (hī'pēr-ven'ti-lā'shūn) The condition of breathing rapidly and deeply. Hyperventilating decreases the amount of carbon dioxide in the blood.

hypnosis (hīp-nō'sis) A trance-like state usually induced by another person to

- access the subconscious mind and promote healing.
- hypodermis (hī'pō-dēr'mis)** The subcutaneous layer of the skin that is largely made of adipose tissue.
- hypoglycemia (hī'pō-glī-sē'mē-ă)** Low blood sugar.
- hyporeflexia (hī'pō-rē-flek'sē-ă)** A condition of decreased reflexes.
- hypotension (hī'pō-tēn'shūn)** Low blood pressure.
- hypothalamus (hī'pō-thal'ă-mūs)** A region of the diencephalon. It maintains homeostasis by regulating many vital activities such as heart rate, blood pressure, and breathing rate.
- hypovolemic shock (hī'pō-vō-lē'mik shok)** A state of shock resulting from insufficient blood volume in the circulatory system.
- hypoxemia (hī'pok-sē'mē-ă)** Subnormal oxygenation of arterial blood, short of anoxia.
- hypoxia (hī'pok'sē-ă)** Inadequate oxygenation of the cells of the body.
- hysterectomy (his'tēr-ek'tō-mē)** Surgical removal of the uterus.
- ICD-10** See *International Classification of Diseases, Tenth Revision*.
- icons (ī'konz')** Pictorial images; on a computer screen, graphic symbols that identify menu choices.
- identification line (ī-den'ti-fi-kā'shūn līn)** A line at the bottom of a letter containing the letter writer's initials and the typist's initials.
- idiopathic (īd-ē-ō-path'ik)** A disease or condition of unknown cause.
- IFFA** See **immunofluorescent antibody test**.
- ileocecal sphincter (il'ē-ō-sē'kāl sfīngk'tēr)** A structure that controls the movement of chyme from the ileum to the cecum.
- ileum (il'ē-əm)** The last portion of the small intestine. It is directly attached to the large intestine.
- ilium (il'ē-ūm)** The most superior part of the hip bone. It is broad and flaring.
- immunity (i-myū-ni-tē)** The condition of being resistant or not susceptible to pathogens and the diseases they cause.
- immunizations (im'yū-nī-zā-shūnz)** Administration of a vaccine to protect susceptible individuals from communicable diseases.
- immunocompromised (im'yū-nō-kom'promīzd)** Having an impaired or weakened immune system.
- immunofluorescent antibody (IFFA) test (im'yū-nō-flōr-es'ent an'ti-bod-ē test)** A blood test used to confirm enzyme-linked immunosorbent assay (ELISA) test results for HIV infection.
- immunoglobulins (im'yū-nō-glob'yū-līnz)** A class of structurally related proteins that include IgG, IgA, IgM, and IgE; also called **antibodies**.
- impetigo (im'pē-tīgō)** A contagious skin infection usually caused by germs commonly called staph and strep.
- implied consent (im-plīd' kōn-sent')** A form of consent that is not expressly granted by a person, but rather inferred from a person's actions and the facts and circumstances of a particular situation (or in some cases by a person's silence or inaction).
- implied contract (īm-plīd' kon'trakt)** A contract that is created by the acceptance or conduct of the parties rather than the written word.
- impotence (im'pō-tēns)** A disorder in which a male cannot maintain an erect penis to complete sexual intercourse; also called **erectile dysfunction**.
- inactive file (in-ak'tiv fīl)** A file used infrequently.
- incident report (in'si-dēnt rē-pōrt')** A report required by a facility when an adverse incident with risk of liability occurs.
- incision (in-sīzh'ūn)** A surgical wound made by cutting into body tissue.
- incisors (in-sīzōrz)** The most medial teeth. They act as chisels to bite off food.
- incomplete proteins (in'kōm-plēt' prō'tēnz)** Proteins that lack one or more of the essential amino acids.
- incontinence (in-kon'ti-nens)** The involuntary leakage of urine.
- incus (īng'kūs)** A small bone in the middle ear, located between the malleus and the stapes; also called the anvil.
- indexing (in'dēks' īng)** The naming of a file.
- indexing rules (in'dēks' īng rūlz)** Rules used as guidelines for the sequencing of files based on current business practice.
- indication (in'di-kā'shūn)** The purpose or reason for using a drug, as approved by the FDA.
- indirect filing system (in'dir-ekt' fīl-īng sis'tēm)** A numeric filing system, which organizes files by numbers instead of by names.
- individual identifiable health information (IIHI) (in'di-vij'yū-ăl ī-den'ti-fi'ă-bēl helth in'fōr-mā'shūn)** Any part of an individual's health information, including demographic information, collected from an individual that is received by a covered entity (e.g., a healthcare provider).
- induction (in-dūk'shūn)** The pregnant patient is admitted to the delivering healthcare facility, then given medication to start uterine contractions.
- induration (in'dūr-ă'shūn)** The process of hardening or of becoming hard.
- infection (in-fek'shūn)** The presence of a pathogen in or on the body.
- infectious waste (in-fek'shūs wāst)** Waste that can be dangerous to those who handle it or to the environment; includes human waste, human tissue, and body fluids as well as potentially hazardous waste, such as used needles, scalpels, and dressings, and cultures of human cells.
- inferior (in-fēr'ē-ōr)** Anatomical term meaning below or closer to the feet; also called **caudal**.
- infertility (in'fēr-tīl'i-tē)** Diminished ability to produce offspring; does not imply sterility.
- inflammation (in'flā-mā'shūn)** The body's reaction when tissue becomes injured or infected. The four cardinal signs are redness, heat, pain, and swelling.
- inflammatory phase (in-flam'ă-tōr-ē fāz)** The initial phase of wound healing in which bleeding is reduced as blood vessels in the affected area constrict.
- informed consent (in-fōrmd' kōn-sent')** The patient's right to receive all information relative to his or her condition and then make a decision regarding treatment based upon that knowledge.
- informed consent form (in-fōrmd' kōn-sent' fōrm)** A form that verifies that a patient understands the offered treatment and its possible outcomes or side effects.
- infundibulum (in-fūn-dīb'yū-lūm)** The funnel-like end of the uterine tube near an ovary. It catches the secondary oocyte as it leaves the ovary.

- infusion (in-fyū'zhūn)** A slow drip, as of an intravenous solution into a vein.
- ink-jet printer (īngk'jēt' prīn'tēr)** A nonimpact printer that forms characters by using a series of dots created by tiny drops of ink.
- innate immunity (i-nāt' i-myū'ni-tē)** The body's mechanisms to protect itself against pathogens in general; also called nonspecific defenses.
- inner cell mass (in'ēr sel mas)** A group of cells in a blastocyte that gives rise to an embryo.
- inorganic (in'ōr-gan'ik)** Matter that generally does not contain carbon and hydrogen.
- insertion (in-sēr'shūn)** An attachment site of a skeletal muscle that moves when a muscle contracts.
- inside address (īn-sīd' ā-dres')** The name and address of the person to whom the letter is being sent. It appears on a business letter two to four spaces down from the date. It should be two, three, or four lines in length.
- inspecting (conditioning) (in-spek't-ing (kuhn-dih'shun-ing))** The process of making sure an item is ready for filing, including removing paper clips and stapling related documents together.
- inspection (īn-spēk'shūn)** The visual examination of the patient's entire body and overall appearance.
- inspiration (in'spir-ā'shūn)** The act of breathing in; also called inhalation.
- instruction set (in-strūkt'shūn set)** Includes the groups of instructions from installed programming that a CPU can implement.
- insulin (in'sū-lin)** A hormone that regulates the amount of sugar in the blood by facilitating its entry into the cells.
- integrative medicine (in'tē-grā-tiv med'i-sin)** The combination of components of conventional medicine with complementary and alternative medicine modalities.
- integrity (in-teg'ri-tē)** Adhering to the appropriate code of law and ethics and being honest and trustworthy.
- interactive pager (in'tēr-ak'tiv pāj'ēr)** A pager designed for two-way communication. The pager screen displays a printed message and allows the physician to respond by way of a mini-keyboard.
- interatrial septum (in'tēr-ā'trē-āl sep'tūm)** The wall separating the right and left atria from each other.
- intercalated disc (in-ter'kā-lā-ted disk)** A disk that connects groups of cardiac muscles. This disc allows the fibers in that group to contract and relax together.
- interferon (in-tēr-fēr'on)** A protein that blocks viruses from infecting cells.
- interim room (īn'tēr-īm rūm)** A room off the patient reception area and away from the examination rooms for occasions when patients require privacy.
- International Classification of Diseases (in'tēr-nash'ūn-āl klas'i-fi-kā'shūn dī-zēz'ēz)** Code set that is based on a system maintained by the World Health Organization of the United Nations. The use of the ICD-10 codes in the health-care industry is mandated by HIPAA for reporting patients' diseases, conditions, and signs and symptoms. ICD-10 codes, adopted 10/1/15, allow for more specificity and accuracy when coding.
- Internet (īn'tēr-net)** A global network of computers.
- interneurons (in'tēr-nū'ronz)** Structures found only in the central nervous system that link sensory and motor neurons together.
- internist (īn'tēr'nīst)** A doctor who specializes in diagnosing and treating problems related to the internal organs.
- interpersonal skills (in'tēr-pēr'sōn-āl skīlz)** Attitudes, qualities, and abilities that influence the level of success and satisfaction achieved in interacting with other people.
- interphalangeal (in'tēr-fā-lan'jē-āl)** Pertaining to the joints between the phalangeal bones.
- interphase (in'tēr-fāz)** The state of a cell carrying out its normal daily functions and not dividing.
- interstitial cell (in'tēr-stish'āl sel)** A cell located between the seminiferous tubules that is responsible for making testosterone.
- interstitial fluid (in'tēr-stish'āl flū'id)** Fluid found between tissue cells that is absorbed by lymphatic capillaries to become lymph.
- interventricular septum (in'tēr-ven-trik'yū-lār sep'tūm)** The wall separating the right and left ventricles from each other.
- intestinal lipase (in-tes'ti-nāl liip'ās)** An enzyme that digests fat.
- intra dermal (ID) (in'trā-der'māl)** Within the upper layers of the skin.
- intra dermal test (in'trā-dēr'māl tēst)** An allergy test in which dilute solutions of allergens are introduced into the skin of the inner forearm or upper back with a fine-gauge needle.
- intramembranous (in'trā-mem'brā-nūs)** A type of ossification in which bones begin as tough, fibrous membranes.
- intramuscular (IM) (in'trā-mūs'kyū-lār)** Within muscle; an IM injection allows administration of a larger amount of a drug than a subcutaneous injection allows.
- intraoperative (in'trā-op'ēr-ā-tiv)** Taking place during surgery.
- intravenous (IV) (in'trā-vē'nūs)** Injected directly into a vein.
- intravenous pyelography (IVP) (in'trā-vē'nūs pīē-log'rā-fē)** A radiologic procedure in which the doctor injects a contrast medium into a vein and takes a series of X-rays of the kidneys, ureters, and bladder to evaluate urinary system abnormalities or trauma to the urinary system; also known as excretory urography.
- intrinsic factor (īn-trīn'zīk fāk'tōr)** A substance secreted by parietal cells in the lining of the stomach. It is necessary for vitamin B₁₂ absorption.
- invasive (īn-vā'siv)** Referring to a procedure in which a catheter, wire, or other foreign object is introduced into a blood vessel or organ through the skin or a body orifice. Surgical asepsis is required during all invasive tests.
- invasive procedure (in-vā'siv prō-sē'jūr)** Any procedure that requires entry into a body cavity or cutting into skin or mucous membranes.
- inventory (in'ven-tōr-ē)** A list of supplies used regularly and the quantities in stock.
- inversion (in-vēr'zhūn)** Turning the sole of the foot medially.
- invoice (īn'vois)** A listing of products or services rendered that is used when billing for that product or service..
- ions (ī'onz)** Positively or negatively charged particles.
- iris (ī'rīs)** The colored part of the eye, made of muscular tissue that contracts and relaxes, altering the size of the pupil.
- ischium (is'kē-ūm)** A structure that forms the lower part of the hip bone.

islets of Langerhans (lĭlēts lahng'er-hahnz) Structures in the pancreas that secrete insulin and glucagon into the bloodstream.

itinerary (i-tĭn'ē-rar'ē) A detailed travel plan listing dates and times for specific transportation arrangements and events, the location of meetings and lodgings, and phone numbers.

IV See **intravenous**.

IVP See **intravenous pyelography**.

jaundice (jawn'dis) A condition characterized by yellowness of the skin, eyes, mucous membranes, and excretions; occurs during the second stage of hepatitis infection.

jejunum (je-jū'nūm) The mid-portion and the majority of the small intestine.

journalizing (jūr'nā-līz'ing) The process of logging charges and receipts in a chronological list each day; used in the single-entry system of bookkeeping.

juxtaglomerular apparatus (jŭks'tā-glō-mer'yū-lār ap-ā-rat'ūs) A structure contained in the nephron and made up of the macula densa and juxtaglomerular cells.

juxtaglomerular cells (jŭks'tā-glō-mēr'yū-lār sēlz) Enlarged smooth muscle cells in the walls of either the afferent or efferent arterioles.

Kaposi's sarcoma (kap'ō-shē sahr-kō'mā) Abnormal tissue occurring in the skin, and sometimes in the lymph nodes and organs, manifested by reddish-purple to dark blue patches or spots on the skin.

keratin (kēr'ā-tĭn) A tough, hard protein contained in skin, hair, and nails.

keratinocyte (kēr-rat'i-nō-sīt) The most common cell type in the epidermis of the skin.

key (kē) The act of inputting or entering information into a computer.

KOH mount (kā'ō-āch mownt) A type of mount used when a physician suspects a patient has a fungal infection of the skin, nails, or hair and to which potassium hydroxide is added to dissolve the keratin in cell walls.

Krebs cycle (krēbz sĭkēl) Also called the citric acid cycle. This cycle generates ATP for muscle cells.

KUB radiography (kā'y—oo-bē rā'dē-og'rā-fē) The process of X-raying the abdomen to help assess the size, shape, and position of the urinary organs;

evaluate urinary system diseases or disorders; or determine the presence of kidney stones. It can also be helpful in determining the position of an intrauterine device (IUD) or in locating foreign bodies in the digestive tract; also called a flat plate of the abdomen.

kyphosis (kī-fō'sis) A deformity of the spine characterized by a bent-over position; more commonly called humpback.

labeling (lā'bēl-ing) Information provided with a drug, including FDA-approved indications and the form of the drug.

labia majora (lā'bē-ā mǎ'jōr-ā) The rounded folds of adipose tissue and skin that protect the other female reproductive organs.

labia minora (lā'bē-ā mĭ'nōr-ā) The folds of skin between the labia majora.

labor relations (lā'bōr rē-lā'shūnz) An HR role that refers to issues that arise between employees and management.

labyrinth (lab'i-rinth) The inner ear.

laceration (las'ēr-ā'shūn) A jagged, open wound in the skin that can extend down into the underlying tissue.

lacrimal apparatus (lak'ri-māl ap-ā-rat'ūs) A structure that consists of the lacrimal glands and nasolacrimal ducts.

lacrimal gland (lak'ri-māl gland) A gland in the eye that produces tears.

lactase (lāk'tās) An enzyme that digests sugars.

lactic acid (lāk'tĭk ās'ĭd) A waste product that must be released from the cell. It is produced when a cell is low on oxygen and converts pyruvic acid.

lactiferous (lak-tĭf'ĭr-ūs) Pertaining to producing milk.

lactogen (lak'tō-jen) Substance secreted by the placenta that stimulates the enlargement of the mammary glands.

lacunae (lā-kū'nē) Holes in the matrix of bone that hold osteocytes.

lamella (lā-mel'ā) Layer of bone surrounding the canals of osteons.

LAN (local area network) (lān) See **local area network**.

lancet (lān'sīt) A small, disposable instrument with a sharp point used to puncture the skin and make a shallow incision; used for capillary puncture.

laryngopharynx (lā-ring'gō-fār-ingks) The portion of the pharynx behind the larynx.

larynx (lār'ĭngks) The part of the respiratory tract between the pharynx and the trachea that is responsible for voice production; also called the voice box.

laser printer (lā'zēr prĭn'tēr) A high-resolution printer that uses a technology similar to that of a photocopier. It is the fastest type of computer printer and produces the highest-quality output.

last menstrual period (LMP) (lāst men'strū-āl pēr'ē-ōd) The date of the first day of the last menstruation; used to determine an estimated expected delivery date for a pregnant patient.

lateral (lat'ēr-āl) A directional term that means farther away from the midline of the body.

lateral file (lat'ēr-āl fĭl) A horizontal filing cabinet that features doors that flip up and a pull-out drawer, where files are arranged with sides facing out.

laterality (lat'ēr-al'i-tē) In ICD-10, the side of the body affected by the diagnosis.

law (lō) A rule of conduct established and enforced by an authority or governing body, such as the federal government.

law of agency (law ā'jēn-sē) A law stating that an employee is considered to be acting on the physician's behalf while performing professional duties.

lead (lēd) A view of a specific area of the heart on an electrocardiogram.

lease (lēs) To rent an item or piece of equipment.

legal custody (lā-gal' kŭs'tō-dē) The court-decreed right to have control over a child's upbringing and to take responsibility for the child's care, including healthcare.

lens (lenz) A clear, circular disc located in the eye, just posterior to the iris, that can change shape to help the eye focus images of objects that are near or far away.

lentigos (len-tĭ'gōz) Brown macules resembling a freckle except that the border is usually regular and microscopic proliferation of rete ridges is present; scattered melanocytes are seen in the basal cell layer. They are usually caused by sun exposure in someone of middle age or older.

letterhead (lēt'ēr-hēd') Formal business stationery, with the doctor's (or office's) name and address printed at the top, used for correspondence with patients, colleagues, and vendors.

leukemia (lū-kē'mē-ă) A medical condition in which bone marrow produces a large number of white blood cells that are not normal.

leukocyte (lū'kō-sīt) White blood cell.

leukocytosis (lū'kō-sī-tō'sis) A white blood cell count that is above normal.

leukopenia (lū'kō-pē'nē-ă) A white blood cell count that is below normal.

LH See **luteinizing hormone**.

liability insurance (lī'ă-bil'ī-tē in-shūr'ents) A type of insurance that covers injuries caused by the insured or injuries that occurred on the insured's property.

liable (lī'ă-bēl) Legally responsible.

libel (lī'bēl) A false publication, as in writing, print, signs, or pictures, that damages a person's reputation.

licensed practitioner (lī'sēnst prak'ti'shūn-ēr) A healthcare provider who has obtained the necessary education and skills and is licensed to provide specified healthcare to patients.

lifetime maximum benefit (līf'tīm' mak'si-mūm ben'ē-fit) The total sum that a health plan will pay out over the patient's life.

ligament (lig'ă-mēnt) A tough, fibrous band of tissue that connects bone to bone.

ligature (lig'ă-chūr) Suture material.

limbus (lim'būs) The corneal-scleral junction, which is the area where the sclera (the white of the eye) gives way to the clear covering of the iris (cornea).

limited check (līm'ī-ted chek) A check that is void after a certain time limit; commonly used for payroll.

lingual frenulum (ling'gwāl fren'yūlūm) A flap of mucosa that holds the body of the tongue to the floor of the oral cavity.

lingual tonsils (ling'gwāl ton'silz) Two lumps of lymphatic tissue at the back of the tongue that destroy bacteria and viruses.

linoleic acid (lin-ō-lē'ik as'id) An essential fatty acid found in corn and sunflower oils.

lipid (lip'id) "Fat-soluble," an operational term describing a solubility

characteristic, not a chemical substance, denoting substances extracted from animal or vegetable cells by nonpolar solvents; included in the heterogeneous collection of materials thus extractable are fatty acids, glycerides, glyceryl ethers, phospholipids, sphingolipids, long-chain alcohols, waxes, terpenes, steroids, and "fat-soluble" vitamins such as A, D, and E.

lipoproteins (lip-ō-prō'tēnz) Large molecules that are fat-soluble on the inside and water-soluble on the outside and carry lipids such as cholesterol and triglycerides through the bloodstream.

lithotripsy (lith'ō-trip-sē) The crushing of a stone in the renal pelvis, ureter, or bladder by mechanical force or sound waves.

living will (līv'ing wīl) A legal document addressed to a patient's family and healthcare providers stating what type of treatment the patient wishes or does not wish to receive if terminally ill, unconscious, or permanently comatose; sometimes called an advance directive.

lobe (lōb) The frontal, parietal, temporal, or occipital region of the cerebral hemisphere.

local area network (LAN) (lō'kāl ār'ē-ă net'wōrk) A network that connects computers in one building or a group of buildings.

locum tenens (lō'kum ten'enz) A substitute physician hired to see patients while the regular physician is away from the office.

loop electrosurgical excision procedure (LEEP) (lūp ē-lek'trō-sūr'jik-ăl ek-sizh'ūn prō-sē'jūr) A diagnostic and therapeutic gynecologic surgical technique for removing dysplastic cells from the cervix with a small wire loop.

loop of Henle (lūp hen'lē) The portion of the renal tubule that curves back toward the renal corpuscle and twists again to become the distal convoluted tubule.

lubricant (lū'bri-kānt) A water-soluble gel used during examination of the rectum or vaginal cavity.

lumbar enlargement (lūm'bahr en-lahrj'mēnt) The thickening of the spinal cord in the low back region.

lunula (lūn'yū-lă) The white, half-moon-shaped area at the base of a nail.

luteinizing hormone (LH) (lū'tē-in-īzing hōr'mōn) Hormone that in females stimulates ovulation and the production of estrogen; in males, it stimulates the production of testosterone.

lymph (limf) The fluid inside lymphatic vessels.

lymphedema (limf'ē-dē'mă) The blockage of lymphatic vessels that results in the swelling of tissue from the accumulation of lymphatic fluid.

lymph nodes (limf nōdz) Very small, glandular structures that filter pathogens from lymph and generate lymphocytes.

lymphocytes (limf'ō-sīts) Granular leukocytes formed in lymphoid tissue. Lymphocytes are generally small. See *T lymphocyte* and *B lymphocyte*.

lymphokines (limf'ō-kīnz) A type of cytokine secreted by T cells that increases T-cell production and directly kills cells with antigens.

lysosomes (līsō-sōmz) Structures that are known to perform the digestive function of the cells.

lysozyme (līsō-zīm) An enzyme in tears that destroys pathogens on the surface of the eye.

macrophages (mak'rō-fāj-ez) A type of phagocytic cell found in the liver, spleen, lungs, bone marrow, and connective tissue. Macrophages play several roles in humoral and cell-mediated immunity, including presenting the antigens to the lymphocytes involved in these defenses; also known as monocytes while in the bloodstream.

macula densa (mak'yū-lă den'sa) An area of the distal convoluted tubule that touches afferent and efferent arterioles.

macular degeneration (mak'yū-lahr dė-jen'ēr-ă-shūn) A progressive disease that usually affects people older than the age of 50. It occurs when the retina no longer receives an adequate blood supply.

magnetic resonance imaging (MRI) (mag-net'ik rez'ō-nāns im'aj-ing) A viewing technique that uses a powerful magnetic field to produce an image of internal body structures.

magnetic therapy (măg-nēt'ik thār'ă-pē) A type of therapy in which magnets are placed on the body to penetrate and correct the body's energy fields.

maintenance contract (mān'tē-nāns kon'trakt) A contract that specifies when a piece of equipment will be

- cleaned, checked for worn parts, and repaired.
- major histocompatibility complex (MHC)** (mā'jör his'tō-kōm-pat'i-bil'i-tē kom'pleks) A large protein complex that plays a role in T-cell activation.
- malignant** (mā-lig'nānt) A type of tumor or neoplasm that is invasive and destructive and that tends to metastasize; it is commonly known as cancerous.
- malleus** (māl'ē-ūs) A small bone in the middle ear that is attached to the eardrum; also called the hammer.
- malpractice claim** (mal-prak'tis clām) A lawsuit brought by a patient against a physician for errors in diagnosis or treatment.
- maltase** (mawl'tās) An enzyme that digests sugars.
- mammary glands** (mam'ā-rē glāndz) Accessory organs of the female reproductive system that secrete milk after pregnancy.
- mammography** (mā-mog'rā-fē) X-ray examination of the breasts.
- managed care organization (MCO)** (man'ājōd kār ōr gān-i-zā'shūn) A healthcare business that, through mergers and buyouts, can deliver healthcare more cost-effectively.
- mandible** (man'di-bēl) A bone that forms the lower portion of the jaw.
- manipulation** (mā-nip'yū-lā'shūn) The systematic movement of a patient's body parts.
- margin** (mahr'jin) The space or measurement around the edges of a form or letter that is left blank.
- marrow** (ma'rō) A substance that is contained in the medullary cavity. In adults, it consists primarily of fat.
- massage** (mā-sahzh') The use of pressure, kneading, stroking, and the human touch to alleviate pain and promote healing through relaxation.
- massage therapist** (mā-sahzh' thār'ā-pist) An individual who is trained to use pressure, kneading, and stroking to promote muscle and full-body relaxation.
- mastoid process** (mas'toyd pros'es) A large bump on each temporal bone just behind each ear. It resembles a nipple, hence the name mastoid.
- matrix** (mā'triks) The basic format of an appointment book, established by blocking off times on the schedule during which the doctor is able to see patients. Also, the material between the cells of connective tissue.
- matter** (māt'er) Anything that takes up space and has weight. Liquids, solids, and gases are matter.
- maturation phase** (mach'ūr-ā'shūn fāz) The third phase of wound healing, in which scar tissue forms.
- maxilla** (mak-sil'ā) A bone that forms the upper portion of the jaw.
- Mayo stand** (mā'ō stānd) A movable stainless steel instrument tray on a stand.
- MCO** See **managed care organization**.
- meaningful use** (mēn'ing-ful yūs) The use of certified electronic health record technology to improve quality, safety, and efficiency, and reduce health disparities; to engage patients and family; to improve care coordination, and population and public health; and to maintain privacy and security of patient health information.
- mechanical digestion** (mē-kan'i-kāl dī-jes'chūn) The breaking down of food for use by the body by a physical method such as chewing.
- medial** (mē'dē-āl) A directional term that describes areas closer to the midline of the body.
- mediation** (mē'dē-ā'-shun) Intervention in a dispute in order to resolve it.
- Medicaid** (med'i-kād) A federally funded health cost-assistance program for low-income, blind, and disabled patients; families receiving aid to dependent children; foster children; and children with birth defects.
- medical asepsis** (med'i-kāl ā-sep'sis) Measures taken to reduce the number of microorganisms, such as handwashing and wearing examination gloves, that do not necessarily eliminate microorganisms; also called clean technique.
- medical identity theft** (med'i-kāl ī-den'ti-tē theft) Using another person's name or insurance to seek healthcare.
- medical practice act** (med'i-kāl prak'tis akt) A law that defines the exact duties that physicians and other healthcare personnel may perform.
- Medicare** (med'i-kār) A national health insurance program for Americans aged 65 and older.
- Medicare Choice Plan** (med'i-kār choys plan) Medicare benefit in which beneficiaries can choose to enroll in one of three major types of plans instead of the Original Medicare Plan.
- Medigap** (med'i-gap) Private insurance that Medicare recipients can purchase to reduce the gap in coverage—the amount they would have to pay from their own pockets after receiving Medicare benefits.
- meditation** (mēd'ī-tā'shūn) A state in which the body is consciously relaxed and the mind becomes calm and focused.
- medullary cavity** (med'ū-lar'ē kav'i-tē) The canal that runs through the center of the diaphysis.
- megakaryocytes** (meg-ā-kar'ē-ō-sīts) Cells within red blood marrow that give rise to platelets.
- meiosis** (mī-ō'sis) A type of cell division in which each new cell contains only one member of each chromosome pair.
- melanin** (mel'ā-nīn) A pigment that is deposited throughout the layers of the epidermis.
- melanocyte** (mel'ā-nō-sīt) A cell type within the epidermis that makes the pigment **melanin**.
- melanocyte-stimulating hormone (MSH)** (mel'ā-nō-sīt stim'yū-lā-tīng hōr'mōn) A hormone released from the anterior pituitary to stimulate melanin production in the skin's epidermal cells.
- melatonin** (mēl'ā-tō'nīn) A hormone that helps to regulate circadian rhythms.
- membrane potential** (mem'brān pō-ten'shāl) The potential inside a cell relative to the fluid outside the cell.
- menarche** (men'-ahrkē) The first menstrual period.
- Ménière's disease** (me-nēr'z' di-zēz') An inner-ear disease characterized by attacks of vertigo, tinnitus, and nausea. Permanent hearing loss may result.
- meninges** (mē-nin'jēz) Membranes that protect the brain and spinal cord.
- meningitis** (mēn'īn-jī'tis) An inflammation of the meninges.
- meniscus** (mē-nis'kūs) The curve in the air-to-liquid surface of a liquid specimen in a container.
- menopause** (men'ō-pawz) The termination of the menstrual cycle due to the normal aging of the ovaries.
- menorrhagia** (men'ō-rā'jē-ā) Excessively prolonged or profuse menses.

menses (mĕn'sēz) The clinical term for menstrual flow.

menstrual cycle (men'strū-ăl sī'kĕl) The female reproductive cycle. It consists of regular changes in the uterine lining that lead to monthly bleeding.

menstruation (men'strū-ă'shŭn) Cyclic endometrial shedding and discharge of a bloody fluid from the uterus during the menstrual cycle.

mensuration (men'sŭr-ă'shŭn) The process of measuring.

meridians (mĕr-id'ĕ-anz) Pathways of energetic flow that are distributed symmetrically throughout the body. These pathways are used in acupuncture, traditional Chinese medicine, and Ayurveda.

mesentery (mes'ĕn-ter-ĕ) The fan-like tissue that attaches the jejunum and ileum to the posterior abdominal wall.

mesoderm (mez'ō-derm) The primary germ layer that gives rise to connective tissue and some epithelial tissue.

metabolic wastes (met'ă-bol'ik wăsts) Substances produced during the normal operation of the kidneys and excreted through the urine.

metabolism (mĕ-tab'ĕ-lizm) The overall chemical functioning of the body, including all body processes that build small molecules into large ones (anabolism) and break down large molecules into small ones (catabolism).

metacarpal (met'ă-kahr'pāl) One of the bones that form the palms of the hand.

metacarpophalangeal (met'ă-kahr'pō-fă-lan'jĕ-ăl) Pertaining to the joints that join the phalanges to the metacarpals.

metaphase (met'ăfăz) Period of mitosis when the chromosomes line up on the spindle fibers created by the centrioles during prophase.

metastasis (mĕ-tas'tă-sis) The transfer of abnormal cells to body sites far removed from the original tumor; the spread of tumor cells.

metatarsal (met'ă-tahr'săl) One of the bones that form the front of the foot.

metatarsophalangeal (met'ă-tahr'sō-fă-lan'jĕ-ăl) Pertaining to the joints that join the phalanges to the metatarsals.

metric system (met'rik sis'tĕm) A system of measurement based on multiples of 10.

metrorrhagia (mĭ'krō-bĭ-ol'ō-jĕ) Any irregular, acyclic bleeding from the uterus between periods.

MHC See **major histocompatibility complex**.

microbiology (mĭ'krō-bĭ-ol'ō-jĕ) The study of microorganisms.

microfiche (mĭ'krō-fĕsh') Microfilm in rectangular sheets.

microfilm (mĭ'krō-film) A roll of film stored on a reel and imprinted with information on a reduced scale to minimize storage space requirements.

microglia (mĭ-krōg'lĕa) Small cells within the nervous system that act as phagocytes, watching for and engulfing invaders.

microorganism (mĭ'krō-ōr'gănz-izm) A simple form of life, commonly made up of a single cell and so small that it can be seen only with a microscope.

micropipette (mĭ'krō-pĭ-pĕt') A small pipette that holds a small, precise volume of fluid; used to collect capillary blood.

microvilli (mĭ'krō-vĭl'ĭ) Structures found in the lining of the small intestine. They greatly increase the surface area of the small intestine so that it can absorb many nutrients.

micturition (mik-chŭr-ish'ŭn) The process of urination.

middle digit (mid'ĕl dij'it) A small group of two to three numbers in the middle of a patient number that is used as an identifying unit in a filing system.

midlevel provider (mid-lev'ĕl prō-vĭdĕr) Physician assistant or nurse practitioner who provides patient care under the supervision of a physician.

midsagittal (mid'saj'i-tăl) Anatomical term that refers to the plane that runs lengthwise down the midline of the body, dividing it into equal left and right halves.

mineral (min'ĕr-ăl) Natural, inorganic substance the body needs to help build and maintain body tissues and carry on life functions.

minor (mĭ'nōr) Anyone under the age of majority—18 in most states, 21 in some jurisdictions.

minutes (min'ŭtz) A report of what happened and what was discussed and decided at a meeting.

mirroring (mir'ōr-ing) Restating in your own words what a person is saying.

misdemeanor (mis'di-mĕn-ōr) A less serious crime such as theft under a certain dollar amount or disturbing the peace. A misdemeanor is punishable by fines or imprisonment.

mitochondria (mĭ'tō-kon'drĕ-ă) Structures that provide energy for cells and are the respiratory centers for the cell.

mitosis (mĭ-tō'sĭs) A type of cell division that produces ordinary body, or somatic, cells; each new cell receives a complete set of paired chromosomes.

mitral valve (mĭ'trăl vălv) See **bicuspid valve**.

mobility aid (mō-bil'i-tĕ ād) Device that improves one's ability to move from one place to another; also called mobility assistive device.

modeling (mod'ĕl-ing) The process of teaching the patient a new skill by having the patient observe and imitate it.

modem (mō'dĕm) A device used to transfer information from one computer to another through telephone lines.

modified-block letter style (mod'i-fĭd blok let'ĕr stĭl) A letter format similar to full-block style, except that the dateline, complimentary closing, signature block, and notations are aligned and begin at the center of the page or slightly to the right of center.

modified-wave scheduling (mod'i-fĭd wăv sked'jŭl-ing) A scheduling system similar to the wave system, with patients arriving at planned intervals during the hour, allowing time to catch up before the next hour begins.

modifier (mod'i-fĭĕr) One or more 2-digit codes assigned to the 5-digit main code to show that some special circumstance applied to the service or procedure that the physician performed.

molars (mō'lărz) Back teeth that are flat and are designed to grind food.

mold (mōld) Fungi that grow into large, fuzzy, multicelled organisms that produce spores.

molecule (mol'ĕ-kyŭl) The smallest unit into which an element can be divided and still retain its properties; it is formed when atoms bond together.

money order (mŭn'ĕ ôr'dĕr) A certificate of guaranteed payment, which may be purchased from a bank, a post office, or some convenience stores.

monocyte (mon'o-sĭt) A type of phagocyte that is formed in bone marrow and circulates throughout the blood for a very short period of time. It then migrates to specific tissues and is called a macrophage.

monokines (mon'ō kĭnz) A type of cytokine secreted by lymphocytes and macrophages that assists in regulating

- the immune response by increasing B-cell production and stimulating red bone marrow to produce more white blood cells.
- mononucleosis** (mon'ō-nū-klē-ō'sis) A highly contagious viral infection caused by the Epstein-Barr virus (EBV).
- monosaccharide** (mon-ō-sak'ā-rīd) A type of carbohydrate that is a simple sugar.
- mons pubis** (monz pyū'bis) A fatty area that overlies the pubic bone.
- moral values** (mōr'āl val'yūz) Values or types of behavior that serve as a basis for ethical conduct and are formed through the influence of the family, culture, or society.
- morbidity** (mōr-bid'i-tē) The frequency of the appearance of complications following a surgical procedure or other treatment.
- mordant** (mōr'dānt) A substance, such as iodine, that can intensify or deepen the response a specimen has to a stain.
- moro reflex** (mō'rō rē'fleks) A reflex in which an infant's arms spread out and then back in, often with crying, because the infant feels as if she is falling. The moro reflex is a result of the infant's immature nervous system.
- morphology** (mōr-fol'ō-jē) The study of the shape or form of objects.
- mortality** (mōr-tal'i-tē) A fatal outcome.
- morula** (mōr'yū-lā) A zygote that has undergone cleavage and results in a ball of cells.
- motherboard** (mōth'ēr-bōrd)
The main circuit board of a computer that controls the other components in the system.
- motility** (mō-til'i-tē) To be capable of movement.
- motor** (mō'tōr) Efferent neurons that carry information from the central nervous system to the effectors.
- motor nerve** (mō'tōr nērv) An efferent nerve conveying an impulse that excites muscular contraction; motor nerves in the autonomic nervous system also elicit secretions from glandular epithelia.
- mouse** (mous) A pointing device that can be added to a computer that directs activity on the computer screen by positioning a pointer, or cursor, on the screen. It can be directly attached to the computer or can be wireless.
- moxibustion** (mok'sē-būs'chūn) The application of heat at the points where the needles are inserted during acupuncture.
- MRI** See **magnetic resonance imaging**.
- MSH** See **melanocyte-stimulating hormone**.
- mucocutaneous exposure** (myū'kō-kyū-tā'nē-ūs eks-pō'zhūr) Exposure to a pathogen through mucous membranes.
- mucosa** (myū-kō'sā) The innermost layer of the wall of the alimentary canal.
- mucous cells** (myū'kūs selz) Cells that are found in the salivary glands and the lining of the stomach and that secrete mucous.
- MUGA scan (nuclear ventriculography)** (mūg'ā skan [nōōklē-ēr ven-trī-kyōō-log'rā-fē]) A radiologic procedure that evaluates the condition of the heart's myocardium; it involves injection of radioisotopes that concentrate in the myocardium, followed by the use of a gamma camera to measure ventricular contractions to evaluate the patient's heart wall.
- multimedia** (mūl'tē-mē'dē-ā) More than one medium, such as in graphics, sound, and text, used to convey information.
- multiskilled healthcare professional (MSHP)** (mūl'tē skild helth'kār prō-fesh'i-nāl) A healthcare team member who has been cross-trained to handle many different duties.
- multi-unit smooth muscle** (mūl'tē yū'nit smūth mūs'ēl) A type of smooth muscle that is found in the iris of the eye and in the walls of blood vessels.
- murmur** (mūr'mūr) An abnormal heart sound heard when the ventricles contract and blood leaks back into the atria.
- muscle fatigue** (mus'ēl fā-tēg') A condition caused by a buildup of lactic acid.
- muscle fibers** (mūs'ēl fī'bērz) Muscle cells that are called fibers because of their long lengths.
- muscle tissue** (mūs'ēl tish'ū) A tissue type that is specialized to shorten and elongate.
- muscular dystrophy** (mūs'kyū-lār dis'trō-fē) A group of inherited disorders characterized by a loss of muscle tissue and by muscle weakness.
- mutation** (myū-tā'shūn) An error that sometimes occurs when DNA is duplicated. When it occurs, it is passed to descendent cells and may or may not affect them in harmful ways.
- myasthenia gravis** (mī-as-thē'nē-ā grāv'is) An autoimmune disorder that is characterized by muscle weakness.
- myelin** (mī'ē-lin) A fatty substance that insulates the axon and allows it to send nerve impulses quickly.
- myelin sheath** (mī'ē-lin shēth) Insulation around some nerve cell axons that allows nerve impulses to move more quickly through the axons.
- myelography** (mī'ē-log'rā-fē) An X-ray visualization of the spinal cord after the injection of a radioactive contrast medium or air into the spinal subarachnoid space (between the second and innermost of three membranes that cover the spinal cord). This test can reveal tumors, cysts, spinal stenosis, or herniated disks.
- myocardial infarction** (mī'ō-kahr'dē-āl in-fahrk'shūn) A heart attack that occurs when the blood flow to the heart is reduced as a result of blockage in the coronary arteries or their branches.
- myocardium** (mī'ō-kahr'dē-ūm) The middle and thickest layer of the heart. It is made primarily of cardiac muscle.
- myocytes** (mī'ō-sīts) Muscle cells; also called muscle fibers.
- myofibrils** (mī'ō-fī'brils) Long structures that fill the sarcoplasm of a muscle fiber.
- myoglobin** (mī'ō-glō'bin) A pigment contained in muscle cells that stores extra oxygen.
- myoglobinuria** (mī'ō-glō-bi-nyūr'ē-ā) The presence of myoglobin in the urine; can be caused by injured or damaged muscle tissue.
- myometrium** (mī'ō-mē'trē-ūm) The middle, thick, muscular layer of the uterus.
- myopia** (mī'ō'pē-ā) A condition that occurs when light entering the eye is focused in front of the retina; commonly called nearsightedness.
- myxedema** (mik-se-dē'mā) A severe type of hypothyroidism that is most common in women older than 50.
- nail bed** (nāl bēd) The layer beneath each nail.
- narcotic** (nahr-kot'ik) A popular term for an opioid and term of choice in government agencies; see **opioid**.
- nares** (nā'rēz) The openings of the nose, or nostrils.

nasal (nā'zāl) Relating to the nose. The nasal bones fuse to form the bridge of the nose.

nasal conchae (nā'zāl kon'kē) Structures that extend from the lateral walls of the nasal cavity.

nasal mucosa (nā'zāl myū-kō'sā) The lining of the nose.

nasal septum (nā'zāl sēp'tūm) A structure that divides the nasal cavity into a left and right portion.

nasolacrimal duct (nā'zō-lak'ri-māl dūkt) A structure located on the medial aspect of each eyeball. These ducts drain tears into the nose.

nasopharynx (nā'zō-far'ingks) The portion of the pharynx behind the nasal cavity.

National Center for Complementary and Alternative Medicine (NCCAM) (nash'ō-nāl sen'tēr kom'plē-ment'ā-rē awl-tēr'nā-tiv med'i-sin) National organization that conducts and supports CAM research and provides CAM information to healthcare providers and the public.

natural killer (NK) cells (na'chūr-āl kil'ēr selz) Non-B and non-T lymphocytes. NK cells kill cancer cells and virus-infected cells without previous exposure to the antigen.

naturopathic medicine (nā'chūr-ō-path'ik mēd-i-sin) A system of medicine that relies on the healing power of the body and supports that power through various healthcare practices, such as nutritional counseling, lifestyle counseling, and exercise.

needle biopsy (nē'dēl bī'op-sē) A procedure in which a needle and syringe are used to aspirate (withdraw by suction) fluid or tissue cells.

negligence (nēg'li-jēns) A medical professional's failure to perform an essential action or performance of an improper action that directly results in the harm of a patient.

negotiable (nī-gō'shē-ā-bəl) Legally transferable from one person to another.

neonatal period (nē'ō-nā'tāl pēr'-ē-ōd) The first 4 weeks of the postnatal period of an offspring.

neonate (nē'ō-nāt') An infant during the first 4 weeks of life.

nephrologist (ne-frol'ō-jīst) A specialist who studies, diagnoses, and manages diseases of the kidney.

nephrons (nef'ronz) Microscopic structures in the kidneys that filter blood and form urine.

nerve fiber (nērv fī'bēr) A structure that extends from the cell body. It consists of two types: axons and dendrites.

nerve impulse (nērv im'pūls) Electrochemical messages transmitted from neurons to other neurons and effectors.

nervous tissue (nērv'vūs tīsh'ū) A tissue type located in the brain, spinal cord, and peripheral nerves.

netbook (net-buk) A small, portable laptop computer designed for wireless communication and access to the Internet.

net earnings (net ūr'nīngz) Take-home pay, calculated by subtracting total deductions from gross earnings.

network (net'wōrk) A system that links several computers together.

networking (nēt'wōrk-īng) Making contacts with relatives, friends, and acquaintances who may have information about how to find a job in your field.

neuralgia (nūr-al'jē-ā) A medical condition characterized by severe pain along the distribution of a nerve.

neuroglia (nūr-ōg'lēā) Structures that function as support cells for other neurons, including astrocytes, microglia, and oligodendrocytes; also called *neuroglial cells*.

neurologist (nūr-ol'ō-jīst) A specialist who diagnoses and treats disorders and diseases of the nervous system, including the brain, spinal cord, and nerves.

neuron (nūr'on) A nerve cell; it carries nerve impulses between the brain or spinal cord and other parts of the body.

neurotransmitter (nūr'ō-trans'mīt-ēr) A chemical within the vesicles of the synaptic knob that is released into the postsynaptic structures when a nerve impulse reaches the synaptic knob.

neutrophil (nū'trō-fil) A type of granular leukocyte that aids in phagocytosis by attacking bacterial invaders; also responsible for the release of pyrogens.

new patient (nū pā'shēnt) Patient that, for CPT reporting purposes, has not received professional services from the physician within the past 3 years.

NK cells See **natural killer cells**.

nocturia (nok-tyūr'ē-ā) Excessive nighttime urination.

nomogram (nō'mō-gram) A form of line chart showing scales for the variables involved in a particular formula in such a way that corresponding values for each

variable lie in a straight line intersecting all the scales.

noncompliant (non-kōm-plī'ānt) The term used to describe a patient who does not follow the medical advice given.

noninvasive (non-in-vā'siv) Referring to procedures that do not require inserting devices, breaking the skin, or monitoring to the degree needed with invasive procedures.

nonsteroidal hormone (non'ster-oy'dāl hōr'mōn) A type of hormone made of amino acids and proteins.

norepinephrine (nor-ep'i-nef'rin) A neurotransmitter released by sympathetic neurons onto organs and glands for fight-or-flight (stressful) situations.

no-show (nō shō) A patient who does not call to cancel and does not come to an appointment.

nosocomial infection (nō'zō-kō'mē-āl in-fek'shūn) An infection contracted in a hospital.

notations (nō-tā'shūnz) Information found at the end of a business letter indicating enclosures included with the letter and the names of other people who will be receiving copies of the letter.

Notice of Privacy Practices (NPP) (nō'tis prī-vā-sē prak'tis-ēz) A document that informs patients of their rights as outlined under HIPAA.

NPP See **Notice of Privacy Practices**.

nuclear medicine (nū'klē-ār med'i-sin) The use of radionuclides, or radioisotopes (radioactive elements or their compounds), to evaluate the bone, brain, lungs, kidneys, liver, pancreas, thyroid, and spleen; also known as radionuclide imaging.

nucleases (nū'klē-ās-ez) Pancreatic enzymes that digest nucleic acids.

nucleus (nū'klē-ūs) The control center of a cell; contains the chromosomes that direct cellular processes.

numeric filing system (nū-mer'ik fil'-ing sis'tēm) A filing system that organizes files by numbers instead of names. Each patient is assigned a number in the order in which she joins the practice.

nutrient (nū'trē-ēnt) A constituent of food necessary for normal physiologic function.

nystagmus (nis-tag'mūs) Rapid, involuntary eye movements that may be the result of drug or alcohol use, brain injury or lesion, or cerebrovascular accident (CVA).

O&P specimen (ō and pē spes'ī-měŋ) An ova and parasites specimen, or a stool sample, that is examined for the presence of certain forms of protozoans or parasites, including their eggs (ova).

objective (ōb-jek'tīv) Pertaining to data that are readily apparent and measurable, such as vital signs, test results, or physical examination findings.

objective data (ōb-jek'tīv dā'tā) Information about the patient's condition that is readily apparent or measurable.

objectives (ob-jek'tivs) The set of magnifying lenses contained in the nosepiece of a compound microscope.

occipital (ok-sip'i-tāl) Relating to the back of the head. The occipital bone forms the back of the skull.

occult blood (ō-kūlt' blūd) Blood contained in some other substance, not visible to the naked eye.

Occupational Safety and Health Administration (OSHA) See OSHA.

Occupational Safety and Health Act. (ok'yū-pā'shūn-āl sāf'tē helth akt) A set of regulations designed to save lives, prevent injuries, and protect the health of workers in the United States.

OCR See **optical character recognition**.

ocular (ok'yū-lār) An eyepiece of a microscope.

oil-immersion objective (oyl i-mēr'zhūn ōb-jek'tīv) A microscope objective that is designed to be lowered into a drop of immersion oil placed directly above the prepared specimen under examination, eliminating the air space between the microscope slide and the objective and producing a much sharper, brighter image.

ointment (oynt'měnt) A form of topical drug; also known as a salve.

Older Americans Act of 1965 (ōl'dēr ā-mēr'ī-kāns akt) A US law that guarantees certain benefits to elderly citizens, including healthcare, retirement income, and protection against abuse.

olfactory (ōl-fak'tōr-ē) Relating to the sense of smell.

oligodendrocytes (ol'i-gō-den'drō-sīts) Specialized neuroglial cells that assist in the production of the myelin sheath.

oliguria (ol'i-gyūr'ē-ā) Insufficient production (or volume) of urine.

OMM See **osteopathic manipulative medicine**.

oncologist (on-kol'ō-jist) A specialist who identifies tumors and treats patients who have cancer.

onychectomy (ōn-i-kek'tō-mē) The removal of a fingernail or toenail.

oocyte (ō'ō-sīt) The immature egg.

oogenesis (ō-ō-jen'ī-sis) The process of egg cell formation.

open-book account (ō'pēn buk ā-kownt') An account that is open to charges made occasionally as needed.

open-hours scheduling (ō'pēn ovrz sked'jūl-ing) A system of scheduling in which patients arrive at the doctor's office at their convenience and are seen on a first-come, first-served basis.

open posture (ō'pēn pos'chūr) A position that conveys a feeling of receptiveness and friendliness; facing another person with arms comfortably at the sides or in the lap.

ophthalmologist (of'thāl-mol'ō-jist) A medical doctor who is an eye specialist.

ophthalmoscope (of-thal'mō-skōp) A hand-held instrument with a light; used to view inner eye structures.

opioid (ō'-pē-oyd) A natural or synthetic drug that produces opium-like effects.

opportunistic infection (op'ōr-tū-nis'tik in-fek'shūn) Infection by microorganisms that can cause disease only when a host's resistance is low.

optical character reader (OCR) (op'ti-kāl kar'āk-tēr rēd'ēr) An electronic scanner that can "read" typed letters.

optical character recognition (OCR) (op'ti-kāl kar'āk-tēr rek'ōg-nish'ūn) The process or technology of reading data in printed form by a device that scans and identifies characters.

optical microscope (op'ti-kāl mī'krō-skōp) A microscope that uses light, concentrated through a condenser and focused through the object being examined, to project an image.

optic chiasm (ōp'tik kī'azm) A structure located at the base of the brain where parts of the optic nerves cross. It carries visual information to the brain.

optician (op-tish'ān) An eye professional who fills prescriptions for eyeglasses and contact lenses.

optometrist (op-tom'ē-trist) A trained and licensed vision specialist who is not a physician.

orbicularis oculi (ōr-bik'yū-lā'ris ok'yū-lī) The muscle in the eyelid responsible for blinking.

orbit (ōr'bit) The eye socket, which forms a protective shell around the eye.

organ (ōr'gān) Structure formed by the organization of two or more different tissue types that carries out specific functions.

organ of Corti (ōr'gān kōr'tē) The organ of hearing, located within the cochlea of the inner ear.

organelle (ōr'gā-nel') A structure within a cell that performs a specific function.

organic (ōr-gan'ik) Pertaining to matter that contains carbon and hydrogen.

organism (ōr'gā-nizm) A whole living being that is formed from organ systems.

organization (ōr'gān-ī-zā'shūn) A facility or set of coordinated facilities that provide health care.

organizational chart (ōr'gān-ī-zā'shūn-āl chahrt) A formal drawing of the supervisory structure and reporting relationships of an organization such as a medical facility.

organ system (ōr'gān sis'tēm) A system that consists of organs that join together to carry out vital functions.

orifice (ōr'i-fis) An opening.

origin (ōr'i-jin) An attachment site of a skeletal muscle that does not move when a muscle contracts.

Original Medicare Plan (ōr'i-jin'āl med'ī-kār plan) The Medicare fee-for-service plan that allows the beneficiary to choose any licensed physician certified by Medicare.

oropharynx (ōr'ō-far'ingks) The portion of the pharynx behind the oral cavity.

orthopedist (ōr'thō-pē'dist)

A specialist who diagnoses and treats diseases and disorders of the muscles and bones.

orthopnea (ōr-thop'nē'ā) Condition of difficulty breathing except while in an upright position.

orthostatic hypotension (ōr-thō-stat'ik hīpō-ten'shūn) A situation in which blood pressure becomes low and the pulse increases when a patient is moved from a lying to standing position; also known as postural hypotension.

OSHA (ō'shuh) A federal organization (part of the Department of Labor) that ensures safe and healthy working conditions for Americans by enforcing standards and providing workplace safety training.

osmosis (ōz-mō'sis) The diffusion of water across a semipermeable membrane such as a cell membrane.

ossicles (os'i-kēls) Small bones; specifically, one of the bones of the tympanic cavity or middle ear.

ossification (os'i-fi-kā'shūn) The process of bone growth.

osteoarthritis (os'tē-ō-ahr-thrī'tis) Arthritis characterized by erosion of articular cartilage, which becomes soft, frayed, and thinned with eburnation of subchondral bone and outgrowths of marginal osteophytes; pain and loss of function result; mainly affects weight-bearing joints and is more common in women, the overweight, and older people.

osteoblasts (os'tē-ō-blāsts) Bone-forming cells that turn membrane into bone. They use excess blood calcium to build new bone.

osteoclast (os'tē-ō-klast) Bone-dissolving cell. When bone is dissolved, calcium is released into the bloodstream.

osteocyte (os'tē-ō-sīt) A cell of osseous tissue; also called a bone cell.

osteon (os'tē-on) Elongated cylinders that run up and down the long axis of bone.

osteopathic manipulative medicine (OMM) (ōs'tē-ō-pāth'ik mā-nip'yū-lā-tiv med'i-sin) A system of hands-on techniques that help relieve pain, restore motion, support the body's natural functions, and influence the body's structure. Osteopathic physicians study OMM in addition to medical courses.

osteoporosis (os'tē-ō-pōr-ō'sis) An endocrine and metabolic disorder of the musculoskeletal system, more common in women than in men, characterized by hunched-over posture.

osteosarcoma (os'tē-ō-sahr-kō'mā) A type of bone cancer that originates from osteoblasts, the cells that make bony tissue.

OT See **oxytocin**.

otologist (ō-tol'ō-jist) A medical doctor who specializes in the health of the ear.

otorhinolaryngologist (ō-tō-rī'nō-lar-ing-gol'ō-jist) A specialist who diagnoses and treats diseases of the ear, nose, and throat.

otosclerosis (ō'tō-skle-rō'sis) Hardening or immobilization of the stapes within the inner ear.

out guide (owt gīd) A marker made of stiff material and used as a placeholder

when a file is taken out of a filing system.

ova (ōva) Eggs.

oval window (ō'vāl win'dō) The beginning of the inner ear.

overbooking (ō'vēr-buk'ing) Scheduling appointments for more patients than can reasonably be seen in the time allowed.

oviduct (ō'vi-dūkt) A fallopian tube.

ovulation (ov'yū-lā'shūn) The process by which the ovaries release one ovum (egg) approximately every 28 days.

ovum (ō'vūm) One egg. The female "egg" that unites with the male sperm to begin reproduction.

oxygenated (ok'si-jē-nāt-ēd) *Oxygenated blood* refers to blood that has been to the lungs and is carrying oxygen in the hemoglobin.

oxygen debt (ok'si-jēn det) A condition that develops when skeletal muscles are used strenuously for a minute or two.

oxyhemoglobin (ok'sē-hē'mō-glō'bin) Hemoglobin that is bound to oxygen. It is bright red in color.

oxytocin (OT) (ok-sē-tō'sin) A hormone that causes contraction of the uterus during childbirth and the ejection of milk from mammary glands during breastfeeding. (32)

package insert (pak'āj in'sért) A manufacturer's printed guideline for the use and dosing of a drug; includes the pharmacokinetics, dosage forms, and other relevant information about a drug.

packed red blood cells (pākt rēd blud sēlz) Red blood cells that collect at the bottom of a centrifuged blood sample.

palate (pal'āt) The roof of the mouth.

palatine (pal'ā-tīn) Bones that form the anterior portion of the roof of the mouth and the palate.

palatine tonsils (pal'ā-tīn tōn'silz) Two masses of lymphatic tissue located at the back of the throat.

palpation (pal-pā'shūn) A type of touch used by healthcare providers to determine characteristics such as texture, temperature, shape, and the presence of movement.

palpatory method (pal'pā-tōr'ē meth'ōd) Systolic blood pressure measured by using the sense of touch. This measurement provides a necessary preliminary approximation of the systolic blood pressure to ensure an

adequate level of inflation when the actual auscultatory measurement is made.

palpitations (pal'pi-tā'shūn) Unusually rapid, strong, or irregular pulsations of the heart.

pancreatic amylase (pan-krē-at'ik am'il-ās) An enzyme that digests carbohydrates.

pancreatic lipase (pan-krē-at'ik lip'ās) An enzyme that digests lipids.

panel (pān'el) Tests frequently ordered together that are organ or disease oriented.

papillae (pā-pīl'ē) The "bumps" of the tongue in which the taste buds are found. (35)

paranasal sinuses (par'ā-nā'zāl sī'nūs-ēz) Air-filled spaces within skull bones that open into the nasal cavity.

parasite (pā'ā-sīt') An organism that lives on or in another organism and relies on it for nourishment or some other advantage to the detriment of the host organism.

parasympathetic branch (par'ā-sim'pā-thet'ik branch) A branch of the autonomic nervous system that prepares the body for rest and digestion.

parathyroid glands (par'ā-thī'royd glāndz) Four small glands embedded in the posterior thyroid gland that secrete parathyroid hormone (PTH), also known as parathormone.

parathyroid hormone (PH) (par'ā-thī'royd hōr'mōn') A hormone that helps regulate calcium levels in the bloodstream. It increases blood calcium by decreasing bone calcium.

parenteral nutrition (pā-ren'tēr-āl nū-trish'ūn) Nutrition obtained when specially prepared nutrients are injected directly into patients' veins rather than taken by mouth.

paresthesia (par'es-thē'zē-ā) Abnormal sensations ranging from burning to tingling.

parietal (pā-rī'ē-tāl) Bones that form most of the top and sides of the skull.

parietal cells (pā-rī'ē-tāl selz) Stomach cells that secrete hydrochloric acid, which is necessary to convert pepsinogen to pepsin. Parietal cells also secrete intrinsic factor, which is necessary for vitamin B₁₂ absorption.

parietal pericardium (pā-rī'ē-tāl per-i-kar'dē-ūm) The layer on top of the visceral pericardium.

parietal peritoneum (pă-rĭĕ-tăl per'i-tō-nē'ŭm) The lining of the abdominal cavity.

parotid glands (pă-rot'id glandz) The largest of the salivary glands. The parotid glands are located beneath the skin just in front of the ears.

participating physicians (pahr-tis'i-păt-ing fi-zish'ŭnz) Physicians who enroll in managed care plans. They have contracts with MCOs that stipulate their fees.

participatory teaching (pahr-tis'i-pă-to'rē tēch'ing) Method of teaching that includes demonstrations of techniques that may be necessary to show that something has been learned.

partnership (pahrt'nēr-ship) A form of medical practice management in which two or more parties practice together under a written agreement, specifying the rights, obligations, and responsibilities of each partner.

parturition (pah'r'chŭr-ish'ŭn) The act of giving birth.

passive listening (păs'iv līs'ĕn-ing) Hearing what a person has to say without responding in any way; contrast with **active listening**.

patch test (pach test) An allergy test in which a gauze patch soaked with a suspected allergen is taped onto the skin with nonallergenic tape; used to discover the cause of contact dermatitis.

patella (pă-tel'ă) The bone commonly referred to as the kneecap.

pathogen (path'ō-jĕn) A microorganism capable of causing disease.

pathologist (pă-thol'ō-jist) A medical doctor who studies the changes a disease produces in the cells, fluids, and processes of the entire body.

patient advocacy (pă'shĕnt ad'vō-kă-sĕ) The act of speaking and acting on behalf of the patient's needs and well-being.

patient-centered medical home (PCMH) (pă'shĕnt-sen'tĕrd med'i-kăl hōm) A healthcare model designed to change the organization and delivery of primary care in the United States. Primary functions include comprehensive, patient-centered, coordinated care that is accessible and ensures the quality and safety of health-care provided.

patient compliance (pă'shĕnt kōm-pli'āns) Obedience in terms of following a physician's orders.

patient ledger card (pă'shĕnt lej'ēr kahrd) A card containing information

needed for insurance purposes, including the patient's name, address, telephone number, Social Security number, insurance information, employer's name, and any special billing instructions. It also includes the name of the person who is responsible for charges if this is anyone other than the patient.

patient navigator (pă'shĕnt nav'i-gă'tōr) A healthcare professional who helps patients find their way through the sometimes complex healthcare system, helping them overcome any barriers they encounter to ensure that they get the diagnosis and treatment they need in a timely manner.

patient record/chart (pă'shĕnt rĕk'ōrd/chărt) A compilation of important information about a patient's medical history and present condition.

payee (pă-ē') A person who receives a payment.

payer (pă'ēr) A person who pays a bill or writes a check.

pay schedule (pă sked'jŭl) A list showing how often an employee is paid, such as weekly, biweekly, or monthly.

peak expiratory flow rate (PEFR) (pĕk ek-spĭr'ă-tōr-ĕ flō rāt) A measurement taken, usually with a peak flow meter, to determine the amount of air that can be forced quickly from the lungs.

pectoral girdle (pĕk'tōr-ăl gĭr'dĕl) The structure that attaches the arms to the axial skeleton.

pediatrician (pĕ'dĕ-ă-trish'ăn) A specialist who diagnoses and treats childhood diseases and teaches parents skills for keeping their children healthy.

pediculosis (pĕ-dik'yŭ-lō'sis) The medical term for lice.

pegboard system (peg'bōrd sis'tĕm) A bookkeeping system that uses a lightweight board with pegs on which forms can be stacked, allowing each transaction to be entered and recorded on four different bookkeeping forms at once; also called the one-write system.

pelvic girdle (pel'vik gĭr'dĕl) The structure that attaches the legs to the axial skeleton.

pepsin (pep'sin) An enzyme that allows the body to digest proteins.

pepsinogen (pep-sin'ō-jen) Substance that is secreted by the chief cells in the lining of the stomach and becomes pepsin in the presence of acid.

peptidases (pep'ti-dās-ez) Enzymes that digest proteins.

percussion (pĕr-kŭsh'ŭn) Tapping or striking the body to hear sounds or feel vibration.

percutaneous exposure (pĕr'kyū-tă'nē-ŭs eks-pō'zhŭr) Exposure to a pathogen through a puncture wound or needlestick.

pericardium (pĕr-i-kahr'dĕ-ŭm) A membrane that covers the heart and large blood vessels attached to it.

perilymph (per'i-limf) A fluid in the inner ear. When this fluid moves, it activates hearing and equilibrium receptors.

perimetrium (peri-mĕ'trĕ-ŭm) The thin layer that covers the myometrium of the uterus.

perimysium (per'i-mis'ĕ-ŭm) The connective tissue that divides a muscle into sections called fascicles.

perineum (per'i-nĕ-ŭm) In the male, the area between the scrotum and anus; in the female, the area between the vagina and rectum.

periosteum (per'ĕ-os'tĕ-ŭm) The membrane that surrounds the **diaphysis** of a bone.

peripheral nervous system (PNS) (pĕr-if'ĕr-ăl nĕr'vŭs sis'tĕm) A system that consists of nerves that branch off the central nervous system.

peristalsis (per'i-stal'sis) The rhythmic muscular contractions that move a substance through a tract, such as food through the digestive tract and the ovum through the fallopian tube.

peritoneum (per'i-tō-nĕ-ŭm) The double-walled, outermost layer of the alimentary canal; also called the *serosa*.

persistence (pĕr-sis'tĕns) Survival despite opposition or adverse environmental conditions.

personal health record (PHR) (pĕr'sōn-ăl helth rek'ōrd) A health record that provides a summary of medical information, maintained in electronic or other format by an individual, that can be shared with anyone of the patient's choosing.

personal protective equipment (PPE) (pĕr'sōn-ăl prō-tek'tiv ĕ-kwip'mĕnt) Any type of protective gear worn to guard against physical hazards.

personal space (pĕr'sōn-ăl spās) A certain area that surrounds an individual and

- within which another person's physical presence is felt as an intrusion.
- PET** See **positron emission tomography**. (42, 50)
- petty cash fund** (pĕt'ĕ-kăsh fünd) Cash kept on hand in the office for small purchases.
- PH** See **parathyroid hormone**.
- phagocyte** (fag'ō-sīt) A specialized white blood cell that engulfs and digests pathogens.
- phagocytosis** (fag'ō-sī-tō'sis) The process by which white blood cells defend the body against infection by engulfing invading pathogens.
- phalanges** (fă-lan'jĕz) The bones of the fingers.
- pharmaceutical** (fahr'mă-sū'ti-kăl) Pertaining to medicinal drugs.
- pharmacodynamics** (far'mă-kō-dī-nam'iks) The study of what drugs do to the body: the mechanism of action, or how they work to produce a therapeutic effect.
- pharmacognosy** (far-mă-kog'nō-sĕ) The study of characteristics of natural drugs and their sources.
- pharmacokinetics** (far'mă-kō-ki-net'iks) The study of what the body does to drugs: how the body absorbs, metabolizes, distributes, and excretes the drugs.
- pharmacology** (făr'ma-kōl'ō-jĕ) The study of drugs.
- pharmacotherapeutics** (far'mă-kō-thăr'ă-pyū'tiks) The study of how drugs are used to treat disease; also called clinical pharmacology.
- pharyngeal tonsils** (fă-rin'jĕ-ăl tŏn'sils) Two masses of lymphatic tissue located above the palatine tonsils; also called adenoids.
- pharynx** (făr'ĭngks) Structure below the mouth and nasal cavities that is an organ of the respiratory system as well as the digestive system.
- phenylketonuria** (PKU) (fen'il-kĕ'tō-nyūr'ĕ-ă) A genetically inherited disorder in which the body cannot properly metabolize the nutrient phenylalanine, resulting in the buildup of phenylketones in the blood and their presence in the urine. The accumulation of phenylketones results in mental retardation.
- PHI** See **protected health information**.
- philosophy** (fī-lŏs'ĕ-fĕ) The system of values and principles an office has adopted in its everyday practice.
- phlebotomy** (fle-bot'ō-mĕ) The insertion of a needle or cannula (small tube) into a vein for the purpose of withdrawing blood.
- photometer** (fō-tom'ĕ-tĕr) An instrument that measures light intensity.
- PHR** See **personal health record**.
- physiatrist** (fiz-i-a'-trist) A physical medicine specialist, who diagnoses and treats diseases and disorders with physical therapy.
- physical therapy** (fiz'i-kăl thār'ă-pĕ) A medical specialty that uses cold, heat, water, exercise, massage, traction, and other physical means to treat musculoskeletal, nervous, and cardiopulmonary disorders.
- physician assistant (PA)** (fi-zish'ŭn ă-sis'tănt) A healthcare provider who practices medicine under the supervision of a physician.
- physician's office laboratory (POL)** (fi-zish'ŭnz aw'fis lă'brŭh-tō-rĕ) A laboratory contained in a physician's office; processing tests in the POL produces quick turnaround and eliminates the need for patients to travel to other test locations.
- physiology** (fiz'ĕ-ŏl'ŏ-jĕ) The science of the study of the body's functions.
- pineal body** (pin'ĕ-ăl bŏd'ĕ) A small gland located between the cerebral hemispheres that secretes melatonin.
- pitch** (pĭch) The high or low quality in the sound of a person's speaking voice.
- PKU** See **phenylketonuria**.
- placebo effect** (plă-sĕ'bŏ e-fĕkt') The belief that a medication or treatment works even though it is not scientifically substantiated. In research, a placebo is an inactive substance or preparation used as a control to determine the effectiveness of a medicinal drug.
- placenta** (plă-sen'tă) An organ located between the mother and the fetus. It permits the absorption of nutrients and oxygen. In some cases, harmful substances such as viruses are absorbed through the placenta.
- plantar flexion** (plan'tăr flek'shŭn) Pointing the toes downward.
- plasma** (plăz'mă) The fluid component of blood, in which formed elements are suspended; makes up 55% of blood volume.
- plastic surgeon** (plăst'ĭk sŭr'jĕn) A specialist who reconstructs, corrects, or improves body structures.
- platelets** (plăt'lĕt) Fragments of cytoplasm in the blood that are crucial to clot formation; also called thrombocytes.
- pleura** (plŭr'ă) The membranes that surround the lungs.
- pleural effusion** (plŭr'ăl ĕ-fyŭ'zhŭn) A buildup of fluid within the pleural cavity.
- pleurisy** (plŭr'i-sĕ) Also known as pleuritis; this is an inflammation of the parietal pleura of the lungs.
- pleuritis** (plŭr-ī'tis) A condition in which the pleura become inflamed, which causes them to stick together. It can also cause an excess amount of fluid to form between the membranes.
- plexus** (plĕk'sŭs) A structure that is formed when spinal nerves fuse together. It includes the cervical, brachial, and lumbosacral nerves.
- PMS** See **premenstrual syndrome**.
- pneumoconiosis** (nŭ-mŏ-kŏ-nĕ-ŏ'sis) Lung diseases that result from years of exposure to different environmental or occupational types of dust.
- pneumothorax** (nŭ-mŏ-thŏr'aks) The presence of air or gas in the pleural cavity. The lung typically collapses with pneumothorax.
- PNS** See **peripheral nervous system**.
- podiatrist** (pŏ-dĭă-trist) Physician who specializes in the study and treatment of the foot and ankle.
- POL** See **physician's office laboratory**.
- polar body** (pŏ'lăr bod'ĕ) A nonfunctional cell that is one of two small cells formed during the division of an oocyte.
- polarity** (pŏ-lăr'ĭ-tĕ) The condition of having two separate poles, one of which is positive and the other negative.
- polarized** (pŏ'lăr-ĭzd') The state in which the outside of a cell membrane is positively charged and the inside is negatively charged. Polarization occurs when a neuron is at rest.
- policies and procedures (P&P) manual** (pol'i-sĕz prŏ-sĕ'jŭrz) A key written communication tool in the medical office that covers all office policies for administrative and clinical procedures.
- polypharmacy** (pol'ĕ-fahr'mă-sĕ) The administration of many drugs at the same time.
- polysaccharide** (pol-ĕ-sak'ă-rĭd) A type of carbohydrate that is a starch.

POMR The problem-oriented medical record system for keeping patients' charts. Information in a POMR includes the database of information about the patient and the patient's condition, the problem list, the diagnostic and treatment plan, and progress notes.

portfolio (pôrt-fô'lē-ô') A collection of an applicant's résumé, reference letters, and other documents of interest to a potential employer.

positive tilt test (pôz'ī-tīv tīlt tĕst) When the pulse rate increases more than 10 beats per minute (bpm) and the blood pressure drops more than 20 points while taking vital signs in the lying, sitting, and standing positions.

positron emission tomography (PET) (poz'ī-tron ě-mish'ŭn tō-mog'ră-fĕ) A radiologic procedure that entails injecting isotopes combined with other substances involved in metabolic activity, such as glucose. These isotopes emit positrons, which a computer processes and displays on a screen.

postcoital (pôst-kô'ī-tăł) After sexual union.

posterior (pos-tĕr'ĕ-ôr) Anatomical term meaning toward the back of the body. Also called dorsal.

postnatal period (pôst-nă'tăł pĕr'ĕ-ôd) The period following childbirth.

postoperative (pôst-op'ĕr-ă-tiv) Taking place after a surgical procedure.

postural hypotension (pôs-chŭr-ăł hī-pō-tĕn-shŭn) A situation in which blood pressure becomes low and the pulse increases when a patient is moved from a lying to a standing position; also known as orthostatic hypotension.

posture (pôs'chŭr) Body position and alignment.

power of attorney (pow'ĕr ă-tôr'nĕ) The legal right to act as the attorney or agent of another person, including handling that person's financial matters.

PPE See **personal protective equipment**.

PPO See **preferred provider organization**.

practitioner (prak-tish'ŭn-ĕr) One who practices a profession.

practice management system (prak'tis man'ăj-mĕnt sis'tĕm) Multi-functional electronic health system programs which, in addition to medical records management, provide other functionalities including, but not limited to electronic scheduler, billing and accounts

receivable capability, report writer, insurance eligibility and referral management system and billing and coding software.

preauthorization (prĕ'awth'ôr-ī-ză'shun) Authorization or approval for payment from a third-party payer requested in advance of a specific procedure.

pre-certification (prĕ'sĕr-ti-fi-kă'shun) A determination of the amount of money that will be paid by a third-party payer for a specific procedure before the procedure is conducted.

preferred provider organization (PPO) (prĕ-fĕrd' prô-vĭ'dĕr ôr'gă-nĭ-ză'shun) A managed care plan that establishes a network of providers to perform services for plan members.

prefix (prĕ'fĭks) A word part that comes at the beginning of a medical term that alters the meaning of the term.

premenstrual syndrome (PMS) (prĕ-men'strŭ-ăł sin'drôm) A collection of symptoms that occur just before the menstrual period.

premium (prĕ'mĕ-ŭm) The basic annual cost of healthcare insurance.

prenatal period (prĕ-nă'tăł pĭr'ĕ-ôd) The period that includes the embryonic and fetal periods until the delivery of the offspring.

preoperative (prĕ-op'ĕr-ă-tiv) Taking place prior to surgery.

prepuce (prĕ'pyŭs) A piece of skin in the uncircumcized male that covers the glans penis.

presbyopia (prez-bĕ-ô'pĕ-ă) A common eye disorder that results in the loss of lens elasticity. Presbyopia develops with age and causes a person to have difficulty seeing objects close up.

prescribe (prĕ-skrĭb') To give a patient a prescription to be filled by a pharmacy.

prescription (prĕ-skrĭp'shun) A physician's written order for medication.

prescription drug (prĕ-skrĭp'shun drŭg) A drug that can be legally used only by order of a physician and must be administered or dispensed by a licensed healthcare professional.

preventive care (prĕ-ven'tiv kăr) Screening tests and drugs to prevent disease.

preventive medicine (prĕ-ven'tiv med'ī-sin) The branch of medical science concerned with the prevention of disease and with promotion of physical and mental health, through study of the

etiology and epidemiology of disease processes.

primary care physician (PCP) (prĭ'mar-ĕ kăr fi-zish'ăn) A physician who provides routine medical care and referrals to specialists.

primary diagnosis (prĭ'mar-ĕ dĭ-ăg-nô'sis) The diagnosis given as the primary reason for the patient seeking care.

primary germ layer (prĭ'mar-ĕ jĕrm lă'ĕr) An inner cell mass that organizes into layers: the ectoderm, mesoderm, and endoderm.

prime mover (prĭm mŭ'vĕr) The muscle responsible for most of the movement when a body movement is produced by a group of muscles.

primordial follicle (prĭ-môr'dĕ-ăł fol'ī-kĕł) A structure that develops in the ovarian cortex of a female infant before she is born.

principal diagnosis (prin'si-păł dĭ-ăg-nô'sis) The diagnosis that is found, after testing and study, to be the main reason for the patient's need for health-care services.

prioritizing (prĭ-ôr'ī-tĭz-ing) Sorting and dealing with matters in the order of urgency and importance.

Privacy Rule (prĭvă-sĕ rŭł) Common name for the HIPAA Standard for Privacy of Individually Identifiable Health Information, which provides the first comprehensive federal protection for the privacy of health information. The Privacy Rule creates national standards to protect individuals' medical records and other personal health information.

PRL See **prolactin**.

probationary period (prô-bă-shŭn-ăr-ĕ pĕr'ĕ-ôd) A trial period during which the employer may terminate the new employee without cause.

problem solving (prob'lĕm sôlv-ing) A step-by-step approach that uses critical thinking and good judgment to deal with situations or occurrences that need resolution.

procedure code (prô-sĕ'jĕr kôd) Code that represents a medical procedure, such as surgery and diagnostic tests, and medical services, such as an examination to evaluate a patient's condition.

proctologist (prok-tol'ô-jĭst) Physician who diagnoses and treats disorders of the anus, rectum, and intestines.

proctoscopy (prok-tos'kô-pĕ) An examination of the lower rectum and anal canal

with a 3-inch instrument called a proctoscope to detect hemorrhoids, polyps, fissures, fistulas, and abscesses.

professional development (prō-fesh'ŭn-ăl dē-vel'öp-měnt) The skills and knowledge attained for both personal development and career advancement.

professional objective (prō-fesh'un-ăl ōb-jek'tiv) A brief, general statement that demonstrates a career goal.

proficiency testing program (prō-fish'ēn-sē test'ing prō'grām) A required set of tests for clinical laboratories; the tests measure the accuracy of the laboratory's test results and adherence to standard operating procedures.

progesterone (prō-jes'tēr-ōn) A female steroid hormone primarily produced by the ovary.

prognosis (prōg-nō'sis) A prediction of the probable course of a disease in an individual and the chances of recovery.

prolactin (PRL) (prō-lak'tin) A hormone that stimulates milk production in the mammary glands.

prolapse (prō'laps) A sinking of an organ or other part, especially its appearance at a natural or artificial orifice.

proliferation phase (prō-lif'ēr-ā'shŭn fāz) The second phase of wound healing, in which new tissue forms, closing off the wound.

pronation (prō-nā'shŭn) Turning the palms of the hand downward.

pronunciation (prō-nun'cē-ā'shŭn) The sounding out of words.

proofreading (prūf'rēd-ing) Checking a document for formatting, data, and mechanical errors.

prophase (prō'faz) Movement of the replicated centrioles to the opposite ends of the cell, creating spindle-like fibers during mitosis.

proportion (prō-pōr'shŭn) Two fractions that are equal to each other. When three of the four values are known, the fourth value can be calculated by cross-multiplying and solving for the unknown value.

proportion method (prō-pōr'shŭn meth'ōd) A fraction formula based on ratios and proportions that is used to calculate dosage.

prostaglandins (pros-tā-glan'dinz) Local hormones derived from lipid molecules. Prostaglandins typically do not travel in the bloodstream to find their target cells

because their targets are close by. These hormones have numerous effects, including uterine stimulation during childbirth.

prostate gland (prōs'tāt glānd) A chestnut-shaped gland that surrounds the beginning of the urethra in the male.

prostatitis (pros-tā-tī'tis) Inflammation of the prostate gland, which can be acute or chronic.

protected health information (PHI) (prō-tek'tēd helth in'fōr-mā'shŭn) Individually identifiable health information that is transmitted or maintained by electronic or other media, such as computer storage devices. The core of the HIPAA Privacy Rule is the protection, use, and disclosure of protected health information.

protein (prō'tēn) Macromolecules consisting of long sequences of α -amino acids [$\text{H}_2\text{N}-\text{CHR}-\text{COOH}$] in peptide (amide) linkage (elimination of H_2O between the $\alpha\text{-NH}_2$ and $\alpha\text{-COOH}$ of successive residues). Protein is three-fourths of the dry weight of most cell matter and is involved in structures, hormones, enzymes, muscle contraction, immunologic response, and essential life functions. The amino acids involved are generally the 20 α -amino acids (glycine, l-alanine) recognized by the genetic code. Cross-links yielding globular forms of protein are often effected through the 2SH groups of two sulfur-containing l-cysteinyl residues, as well as by noncovalent forces (such as hydrogen bonds, lipophilic attractions).

proteinuria (prō'tē-nyūr'ē-ā) An excess of protein in the urine.

protozoan (prō'tō-zō'ān) A single-celled eukaryotic organism much larger than a bacterium; some protozoans can cause disease in humans.

protraction (prō-trāk'shŭn) Moving a body part anteriorly.

proximal (prōk'si-māl) Anatomical term meaning closer to a point of attachment or closer to the trunk of the body.

proximal convoluted tubule (prōk'simāl kon'vō-lūt'ed tū'byūl) The portion of the renal tubule that is directly attached to the glomerular capsule and becomes the loop of Henle.

psoriasis (sōr-řā-sis) A common skin condition characterized by reddish-silver, scaly lesions most often found on the elbows, knees, scalp, and trunk.

puberty (pyū'bēr-tē) The period of adolescence when a person begins to develop secondary sexual traits and reproductive functions.

pubis (pyū'bis) The area that forms the front of a hip bone.

pulmonary circuit (pul'mō-nār-ē sīr'kūt) The route that blood takes from the heart to the lungs and back to the heart again.

pulmonary circulation (pul'mō-nar-ē sīr'kyū-lā'shŭn) The passage of blood from the right ventricle through the pulmonary artery to the lungs and back through the pulmonary veins to the left atrium.

pulmonary function test (pul'mō-nār-ē fūngk'shŭn test) A test that evaluates a patient's lung volume and capacity; used to detect and diagnose pulmonary problems or to monitor certain respiratory disorders and evaluate the effectiveness of treatment.

pulmonary semilunar valve (pul'mō-nār-ē sem'ē-lū'nār valv) A heart valve that is a semilunar valve. It is situated between the right ventricle and the pulmonary trunk.

pulmonary trunk (pul'mō-nār-ē trŭngk) A large artery that branches into the pulmonary arteries and carries blood to the lungs.

punctuality (pŭngk'chū'āl'i-tē) Showing up on appointed dates and at appointed times.

puncture wound (pungk'shŭr wŭnd) A deep wound caused by a sharp, pointed object.

punitive damages (pyū'ni-tiv dam'ij'iz) Money paid as punishment for intentionally breaking the law.

pupil (pyū'pil) The opening at the center of the iris, which grows smaller or larger as the iris contracts or relaxes, respectively; it regulates the amount of light that enters the eye.

purchase order (pŭr'chās ōr'dēr) A form that authorizes a purchase for the practice.

purchasing groups (pur'chās-ing grŭps) Groups of medical offices associated with a nearby hospital that order supplies through the hospital to obtain a quantity discount.

Purkinje fibers (pŭr-kin'jē fī'bērz) Cardiac fibers located in the lateral walls of the ventricles.

pyelonephritis (pī'ē-lō-ne-frī'tis) A urinary tract infection that involves one or both of the kidneys.

pyloric sphincter (pī-lōr'ik sfīngk'tēr) The valve-like structure composed of a circular band of muscle at the juncture of the stomach and small intestine.

pyothorax (pīō-thōr'aks) Pus or infected fluid in the pleural cavity, causing collapse of the lung.

pyrogens (pīrō-jenz) Fever-producing substances released by neutrophils.

QC See **quality control**.

qi (chē) According to traditional Chinese medicine, a vital energy that flows throughout the body.

quadrant (kwahd'rānt) One of four equal sections, such as those into which the abdomen is figuratively divided during an examination.

qualitative analysis (kwahl'i-tā'tiv ā-nal'i-sis) In microbiology, identification of bacteria present in a specimen by the appearance of colonies grown on a culture plate.

qualitative test response (kwahl'i-tā'tiv test rē-spons') A test result that indicates the substance tested for is either present or absent.

quality assurance (kwahl'i-tē ā-shūr'āns) Procedures that ensure that the services provided in the medical practice meet or exceed requirements and standards.

quality assurance program (kwahl'i-tē ā-shūr'āns prō'gram) A required program for clinical laboratories designed to monitor the quality of patient care, including quality control, instrument and equipment maintenance, proficiency testing, training and continuing education, and standard operating procedures documentation.

quality control (QC) (kwahl'i-tē kōn-trōl') An ongoing system, required in every physician's office, to evaluate the quality of medical care provided.

quality control program (kwahl'i-tē kōn-trōl' prō'gram) A component of a quality assurance program that focuses on ensuring accuracy in laboratory test results through careful monitoring of test procedures.

quantitative analysis (kwahn'ti-tā'tiv ā-nal'i-sis) In microbiology, a determination of the number of bacteria present in a specimen by direct count of colonies grown on a culture plate.

quantitative test results (kwahn'ti-tā'tiv test rē-sūlt) The concentration of a test substance in a specimen.

quantity (Q) (kwahn'ti-tē) Amount of a medication on hand; for example, a pill or an amount of liquid.

quarterly return (kwahr'tēr-lē rē-tūrn') The Employer's Quarterly Federal Tax Return, a form submitted to the IRS every 3 months that summarizes the federal income and employment taxes withheld from employees' paychecks.

qui tam (kwē tahm) Latin, meaning "to bring action for the king and for one's self."

RA See **explanation of benefits, remittance advice**.

radial artery (rā'dē-āl ahr'tēr-ē) An artery located in the groove on the thumb side of the inner wrist, where the pulse is taken on adults.

radiation therapy (rā'dē-ā'shūn thār'ā-pē) The use of X-rays and radioactive substances to treat cancer.

radiography (rā'dē-og'rā-fē) Examination of any part of the body for diagnostic purposes by means of X-rays, with the record of the findings usually impressed on a photographic film.

radiologist (rā'dē-ol'ō-jist) A physician who specializes in taking and reading X-rays.

radius (rā'dē-ūs) The lateral bone of the forearm.

rales (rahlz) Noisy respirations usually due to blockage of the bronchial tubes.

RAM See **random-access memory**.

random-access memory (RAM) (ran'dōm ak'ses mem'ō-rē) The temporary, or programmable, memory in a computer.

random urine specimen (ran'dōm yūr'in spes'i-mēn) A single urine specimen taken at any time of the day; the most common type of sample collected.

range of motion (ROM) (rānj mō'shūn) The degree to which a joint is able to move.

rapport (rā-pōr') A harmonious, positive relationship.

RBRVS See **resource-based relative value scale**.

read-only memory (ROM) (rēd ōn'lē mem'ō-rē) A computer's permanent memory, which can be read by the computer but not changed. It provides the computer with the basic operating instructions it needs to function.

reagent (rē-ā'jēnt) A chemical or chemically treated substance used in test procedures and formulated to react in specific

ways when exposed under specific conditions.

reconciliation (rē-kon-sil'ē-ā'shūn) A comparison of the office's financial records with bank records to ensure that they are consistent and accurate; usually done when the monthly checking account statement is received from the bank.

records management system (rē-kōrdz man'āj-mēnt sis'tēm) How patient records are created, filed, and maintained.

recovery position (rē-kōv'ēr-ē pō-zish'ōn) The position a person is placed in after receiving first aid for choking or cardiopulmonary resuscitation.

rectum (rēk'tūm) The last section of the sigmoid colon that straightens out and becomes the anal canal.

Red Flags Rule (rēd flāgz rūl) A law requiring certain businesses, including most medical offices and other health-care facilities, to develop written programs to detect the warning signs, or red flags, of identity theft.

reference (refer-'rēns) A recommendation for employment from a facility or a preceptor.

reference laboratory (ref'er-rēns lā'brūh-tō-rē) A laboratory owned and operated by an organization outside the physician's practice.

referral (rē-fēr'āl) An authorization from a medical practice for a patient to have specialized services performed by another practice; often required for insurance purposes.

reflection (rē-flek'shūn) When a thought, an idea, or an opinion is formed as a result of deeper thought.

reflex (rē'fleks) A predictable automatic response to stimuli.

reflexology (rē'flek-sol'ō-jē) Manual therapy to the foot and/or hand in which pressure is applied to "reflex" points mapped out on the feet or hands.

refraction (rē-frak'shūn) The bending of light by the cornea, lens, and eye fluids to focus light onto the retina.

refraction examination (rē-frak'shūn eg-zam'i-nā'shūn) An eye examination in which the patient looks through a succession of different lenses to find out which ones create the clearest image.

refractometer (rē-frak-tom'ē-ter) An optical instrument that measures the

refraction, or bending, of light as it passes through a liquid.

Registered Medical Assistant (RMA) (rej'i-stěrd med'i-kāl ā-sis'tānt)

A medical assistant who has met the educational requirements and taken and passed the certification examination for medical assisting given by the American Medical Technologists (AMT).

registration (rej'is-trā'shūn) The recording of information (e.g., licensure, birth or death date).

Reiki (rā'kē) The use of visualization and touch to balance energy flow and bring healthy energy to affected body parts.

relaxin (rē-lak'sin) A hormone that comes from the corpus luteum. It inhibits uterine contractions and relaxes the ligaments of the pelvis in preparation for childbirth.

releasing (rē-lēs'ing) Placing a mark or stamp on an item that indicates that the responsible licensed practitioner has seen the document and is giving permission to file it in the patient's medical record.

remedy (rem'ē-dē) A treatment prescribed by a homeopath in small amounts that in large doses would produce the same symptoms seen in the patient.

remittance advice (RA) (rē-mit'āns ad-vīs') A form that the patient and the practice receive for each encounter that outlines the amount billed by the practice, the amount allowed, the amount of subscriber liability, the amount paid, and notations of any service not covered, including an explanation of why that service is not covered; also called an explanation of benefits.

renal calculi (rē'nāl kal'kyū-lī) Kidney stones.

renal column (rē'nāl kol'ūm) The portion of the renal cortex between the renal pyramids.

renal corpuscle (rē'nāl kōr'pūs-ēl) Corpuscle that is composed of the glomerulus and the glomerular capsule. The filtration of blood occurs here.

renal cortex (rē'nāl kōr'teks) The outermost layer of the kidney.

renal medulla (rē'nāl mē-dūl'ā) The middle portion of the kidney.

renal pelvis (rē'nāl pel'vis) The internal structure of the kidney. Urine flows from the renal pelvis down the ureter.

renal pyramids (rē'nāl pir'ā-midz)

Triangular-shaped areas in the medulla of the kidney.

renal sinus (rē'nāl sī'nūs) The medial depression of a kidney.

renal tubule (rē'nāl tū'byūl)

Structure that extends from the glomerular capsule of a nephron and is composed of the proximal convoluted tubule, the loop of Henle, and the distal convoluted tubule.

renin (rē'nin) A hormone secreted by the kidney that helps to regulate blood pressure.

repolarization (rē-pō'lār-i-zā'shūn) The process of returning to the original polar (resting) state.

reputable (rēp'yū-ti-bēl) Having a good reputation.

requisition (rēk'wī-zish'ūn) A formal request from a staff member or doctor for the purchase of equipment or supplies.

reservoir host (rēz'er-vwahr' hōst) An animal, an insect, or a human whose body is susceptible to growth of a pathogen.

re-sheathing scalpel (rē-sheth'ing skalp'ēl) A single-use, disposable scalpel that has a sheath that can be slid over the blade and locked in position after use.

resident normal flora (rez'i-dēnt nōr' māl flōr'ā) Bacteria, fungi, and protozoa that have taken up residence either in or on the human body. Some of these organisms neither help nor harm the host and some are beneficial, creating a barrier against pathogens.

res ipsa loquitur (res ip'sā lō' kwi-tūr) Latin, meaning "the thing speaks for itself," which is also known as the doctrine of common knowledge.

resource-based relative value scale (RBRVS) (rē'sōrs-bāst rel'ā-tiv val'yū skāl) The payment system used by Medicare. It establishes the relative value units for services, replacing the providers' consensus on usual fees.

respiratory capacity (res'pir-ā-tōr-ē kā-pas'i-tē) The amount of air the lungs can hold; calculated by adding certain respiratory volumes together.

respiratory distress syndrome (res'pir-ā-tōr-ē dis-tres' sin'drōm) Condition found usually in premature babies, who lack the substance surfactant in their lungs, causing the lungs to collapse on expiration.

respiratory hygiene/cough etiquette (res'pir-ā-tōr-ē hīj'en kawf e-ti'ket) Infection control guideline that includes teaching the patient to cover his or her mouth/nose when coughing and dispose of tissues in the proper receptacle.

respiratory volume (res'pir-ā-tōr-ē vol'yūm) The different volumes of air that move into and out of the lungs during different intensities of breathing. These volumes can be measured to assess the healthiness of the respiratory system.

respondeat superior (rē-spon'dē-āt sū-pēr'ē-ōr) Latin, meaning "let the master answer," a doctrine under which an employer is legally liable for the acts of his or her employees, if such acts were performed within the scope of the employee's duties.

restatement (rē-stāt'ment) Repeating what a patient says in your own words back to the patient.

résumé (rē-zūm-ā') A document summarizing one's employment and educational history.

retention schedule (rī-ten'shūn sked'jūl) A schedule that details how long to keep different types of patient records in the office after they have become inactive or closed and how long the records should be stored.

retina (ret'i-nā) The inner layer of the eye; contains light-sensing nerve cells.

retractable needle (rē-trak'tā-bēl nē'dēl) A needle that retracts inside the barrel of a syringe after it is activated.

retraction (rē-trāk'shūn) Moving a body part posteriorly.

retrograde pyelography (ret'rō-grād pī'ē-log'rā-fē) A radiologic procedure in which the doctor injects a contrast medium through a urethral catheter and takes a series of X-rays to evaluate function of the ureters, bladder, and urethra.

retroperitoneal (ret'rō-per'i-tō-nē'āl) An anatomical term that means behind the peritoneal cavity. It is where the kidneys lie.

return demonstration (rē-tūrn' dem'on-strā'shūn) Participatory teaching method in which the technique is first described to the patient and then demonstrated to the patient; the patient is then asked to repeat the demonstration.

reverse chronological order (rē-vērs' kron'ō-loj'ik ēl ōr'dēr) A filing system in which the most recent files (by date)

- are inserted so they are on top of documents with earlier dates in the file folder.
- review of symptoms (rē-vū' simp'tōmz)** A process of gathering information about a patient's health history regardless of apparent relevance to the chief complaint.
- rhabdomyolysis (rab'dō-mī-ol'i-sis)** A condition in which the kidneys have been damaged due to toxins released from muscle cells.
- rhonchi (rong'kī)** Deep snoring or rattling sounds during breathing; associated with asthma, acute bronchitis, or any condition involving partial obstruction of the lung's airway.
- Rh antigen (an'ti-jen)** A protein first discovered on the red blood cells of rhesus monkeys, hence the name Rh.
- RhoGAM (rō'gām)** A medication that prevents an Rh-negative mother from making antibodies against the Rh antigen.
- rhythm strip (rith'ūm strip)** An ECG tracing obtained using an electrocardiograph machine.
- ribosomes (rī'bō-sōmz)** The organelle within the cytoplasm responsible for protein synthesis.
- risk management (RM) (risk man'āj-mēnt)** Plans and processes that continually identify, assess, correct, and monitor functions of the medical office to prevent negative outcomes and minimize exposure to risk and consequent liability.
- RMA** See **Registered Medical Assistant**.
- RNA** A nucleic acid used to make protein.
- rods (rōdz)** Light-sensing nerve cells in the eye, at the posterior of the retina, that function in dim light but do not provide sharp images or detect color.
- ROM** See **read-only memory**.
- rosacea (rō-zā'shē-ā)** A condition characterized by chronic redness and acne over the nose and cheeks.
- rotation (rō-tā'shūn)** Twisting a body part.
- route (rūt)** The way a drug is introduced into the body.
- rubrics (rū'briks)** Three-character ICD categories used to specify diseases, injuries, and symptoms.
- rugae (rū'jē)** The expandable folds of an organ. The folds of the stomach lining.
- sacrum (sā'krūm)** A triangular-shaped bone that consists of five fused vertebra.
- Safety Data Sheet (SDS) (sāf'tē dā'tā shēt)** A form that is required for all hazardous chemicals or other substances used in the laboratory and that contains information about the product's name, ingredients, chemical characteristics, physical and health hazards, guidelines for safe handling, and procedures to be followed in the event of exposure.
- sagittal (saj'i-tāl)** An anatomical term that refers to the plane that divides the body into left and right portions.
- salutation (sal'yū-tā'shūn)** A written greeting, such as "Dear," used at the beginning of a letter.
- sanitization (san'i-tī-zā'shūn)** A reduction of the number of microorganisms on an object or a surface to a fairly safe level.
- sarcolemma (sahr'kō-lem'ā)** The cell membrane of a muscle fiber.
- sarcoplasm (sahr'kō-plazm)** The cytoplasm of a muscle fiber.
- sarcoplasmic reticulum (sahr'kō-plaz'mik rē-tik'yū-lūm)** The endoplasmic reticulum of a muscle fiber.
- SARS (severe acute respiratory syndrome) (sārz)** A severe and acute respiratory illness characterized by fever and a nonproductive cough that progresses to the point at which insufficient oxygen is present in the blood.
- saturated fat (sach'ūr-āt'ēd fat)** Fat, derived primarily from animal sources, that is usually solid at room temperature and that tends to raise blood cholesterol levels.
- scabies (skā'bēz)** Skin lesions that are very itchy and caused by a burrowing mite. Scabies is most commonly found between the fingers and on the genitalia.
- scanner (skan'ēr)** An optical device that converts printed matter into a format that can be read by the computer and inputs the converted information.
- scapula (skap'yū-lā)** Thin, triangular-shaped, flat bone located on the dorsal surface of the rib cage; also called shoulder blade.
- Schwann cells (shwahn sēlz)** Neuroglial cells whose cell membrane coats the axons.
- sciatica (sī-āt'ī-kā)** Pain in the low back and hip radiating down the back of the leg along the sciatic nerve.
- sclera (skler'ā)** The tough, outermost layer, or "white," of the eye, through which light cannot pass; covers all except the front of the eye.
- scoliosis (skō'lē-ō'sis)** A lateral curvature of the spine, which is normally straight when viewed from behind.
- scope of practice (skōp prak'tis)** The procedures, processes, and actions a healthcare worker is allowed to perform under the terms of his or her professional license.
- scored (skōrd)** An indented line on a tablet where the medication can be broken into pieces.
- scratch test (skrāch tēst)** An allergy test in which extracts of suspected allergens are applied to the patient's skin and the skin is then scratched to allow the extracts to penetrate.
- screening (skrēn'ing)** Performing a diagnostic test on a person who is typically free of symptoms.
- screen saver (skrēn sāv'ēr)** A program that automatically changes the monitor display at short intervals or constantly shows moving images to prevent burn-in of images on the computer screen.
- scrotum (skrō'tūm)** In a male, the sac of skin below the pelvic cavity that contains the testes.
- sebaceous (sē-bā'shūs)** A type of oil gland found in the dermis.
- sebum (sē'būm)** An oily substance produced by sebaceous glands.
- secondary diagnosis (sek'ōn-dār-ē dī-āg-nō'sis)** Diagnosis other than the primary diagnosis for other conditions that are also affecting the patient at the time of the visit.
- Security Rule (sē-kyūr'i-tē rül)** The technical safeguards that protect the confidentiality, integrity, and availability of health information covered by HIPAA. The Security Rule specifies how patient information is protected on computer networks, the Internet, disks, and other storage media.
- seizure (sē'zhūr)** A series of violent and involuntary contractions of the muscles; also called a convulsion.
- self-blunting/blunt tip blood drawing needle (self blūnt'ing)** A blood-drawing needle that has a blunt tip that slides forward through the needle past the sharp point to protect the user from needlestick injury.
- self-confidence (self-kōn'fī-dēns)** Believing in oneself; assured.

- self-sheathing needle (self-shēth'ing)** A needle that has a sheath over the barrel of the syringe. After injecting the medication, the user slides the sheath forward over the needle and locks it in place to prevent needlestick injuries.
- sella turcica (sel'ă tūr'sē-kă)** A deep depression in the sphenoid bone where the pituitary gland sits.
- semen (sē'mēn)** Sperm and the various substances that nourish and transport them.
- semicircular canals (sem'ē-sīr'kyū-lăr kă-nalz')** Structures in the inner ear that help a person maintain balance; each of the three canals is positioned at right angles to the other two.
- seminal vesicles (sem'i-năl ves'i-kēlz)** A pair of convoluted tubes that lie behind the bladder. These tubes secrete a fluid that provides nutrition for the sperm.
- seminiferous tubules (sem'i-nif'er-ūs tū'byūlz)** These tubes contain spermatogenic cells and are located in the lobules of the testes.
- sensorineural hearing loss (sen'sēr-ē-nūr'ăl hēr'ing laws)** Hearing loss that occurs when neural structures associated with the ear are damaged. Neural structures include hearing receptors and the auditory nerve.
- sensory (sen'sōr-ē)** Afferent neurons that carry sensory information from the periphery to the central nervous system.
- sensory adaptation (sen'sōr-ē ad'ap-tă' shūn)** A process in which the same chemical can stimulate receptors only for a limited amount of time until the receptors eventually no longer respond to the chemical.
- sensory teaching (sen'sōr-ē tēch'ing)** Method of teaching that provides a patient with a description of the physical sensations he or she may have as part of the learning or the procedure involved.
- septic shock (sēp'tik shōk)** A state of shock resulting from massive, widespread infection that affects the blood vessels' ability to circulate blood.
- sequential order (sē-kwen'shăl ōr'dēr)** One after another in a predictable pattern or sequence.
- serosa (se-rō'să)** The outermost layer of the alimentary canal; also known as the visceral peritoneum.
- serous cells (sēr'ūs sēlz)** One of two types of cells that make up the salivary glands.
- These cells secrete a watery fluid that contains amylase.
- serum (sēr'ūm)** The liquid portion of blood (plasma) when all of the clotting factors have been removed.
- serum separators (sēr'ūm sep'ăr-ă'tōrz)** A type of blood collection tube with an additive that, when spun, forms a gel-like barrier between serum and the clot in a coagulated blood sample.
- service contract (sēr'vis kōn'-trakt)** A contract that covers services for equipment that are not included in a standard maintenance contract.
- severe acute respiratory syndrome** See SARS.
- sex chromosome (seks krō'mō-sōm)** Chromosome of the 23rd pair.
- sex-linked trait (seks'linkt trāt)** Trait carried on the sex chromosomes, or X and Y chromosomes.
- sexual harassment (sek'shū-ăl hăr-ăs'-ment)** Unwelcome verbal, visual, or physical conduct of a sexual nature that is severe or pervasive and affects working conditions or creates a hostile work environment.
- shelter-in-place (shel'tēr in plas)** An interior room or rooms with few or no windows that form a place to take refuge in case of an emergency or a disaster.
- side effects (sīd e-fekts')** Unintended, but fairly mild and common, effects of a medication.
- sigmoid colon (sig'moyd kō'lōn)** An S-shaped tube that lies between the **descending colon** and the **rectum**.
- sigmoidoscopy (sig'moy-dos'kō-pē)** A procedure in which the interior of the sigmoid area of the large intestine, between the descending colon and the rectum, is examined with a sigmoidoscope, a lighted instrument with a magnifying lens.
- sign (sīn)** An objective, or external, factor, such as blood pressure, rash, or swelling, that can be seen or felt by the physician or measured by an instrument.
- signature block (sig'nă-chūr blok)** The writer's name and business title found four lines below the complimentary closing in a business letter.
- silicosis (sil'i-kō'sis)** Chronic lung disease caused by the inhalation of silica dust.
- simplified letter style (sim'pli-fīd let'ēr stīl)** A modification of the full-block style in which the salutation and complimentary closing are omitted and a subject line typed in all capital letters is placed between the address and the body of the letter.
- single-entry account (sing'gēl en'trē ă-kownt)** An account that has only one charge, usually for a small amount, for a patient who does not come in regularly.
- sinoatrial node (SA node) (sīnō-ă'trē-ăl nōd)** A small bundle of heart muscle tissue in the superior wall of the right atrium that sets the rhythm (pattern) of the heart's contractions; also called sinus node or pacemaker.
- sinusitis (sīnŭ-sītis)** Inflammation of the lining of a sinus.
- skinfold test (skīn'fōld tēst)** A method of measuring fat as a percentage of body weight by measuring the thickness of a fold of skin with a caliper.
- skip (skīp)** A patient who has moved without leaving a forwarding address and his bill is unpaid.
- slander (slăn'dēr)** The speaking of defamatory words intended to prejudice others against an individual in a manner that jeopardizes his or her reputation or means of livelihood.
- SLE** See **systemic lupus erythematosus**.
- sleep apnea (slēp ap'nē-ă)** A condition characterized by pauses in breathing during sleep.
- slit lamp (slit lămp)** An instrument composed of a magnifying lens combined with a light source; used to provide a minute examination of the eye's anatomy.
- smear (smēr)** A specimen spread thinly and unevenly across a slide.
- SOAP (sōp)** An approach to medical records documentation that documents information in the following order: S (subjective data), O (objective data), A (assessment), P (plan of action).
- soft skills (sawft skilz)** Personal attributes that enhance an individual's interactions, job performance, and career prospects.
- software (soft'wār)** A program, or set of instructions, that tells a computer what to do.
- sole proprietorship (sōl prō-prī'č-tōr-ship)** A form of medical practice management in which a physician practices alone, assuming all benefits and liabilities for the business.
- solution (sō-lŭ'shŭn)** A homogeneous mixture of a solid, liquid, or gaseous substance in a liquid, such as a dissolved drug in liquid form.

somatic (sō-măt'ík) A division of the peripheral nervous system that connects the central nervous system to skin and skeletal muscle.

somatic nervous system (sō-măt'ík nēr'vūs sis'tēm) A system that governs the body's skeletal, or voluntary, muscles.

SOMR Source-oriented medical record.

SPECT (spēkt) Single photon emission computed tomography; a radiologic procedure in which a gamma camera detects signals induced by gamma radiation and a computer converts these signals into two- or three-dimensional images that are displayed on a screen.

speculum (spek'yū-lŭm) An instrument that expands the vaginal opening to permit viewing of the vagina and cervix.

spermatids (sper'mă-tidz) Immature sperm before they develop their flagella (tails).

spermatocytes (sper-mătō'-sīts) The cells that result when spermatogonia undergo mitosis.

spermatogenesis (sper'mă-t'ō-jen'ě-sis) The process of sperm cell formation.

spermatogenic cells (sper'mă-tō-jen'ik sēlz) The cells that give rise to sperm cells.

spermatogonia (sper'mă-tō-gō'nē-ă) The earliest cell in the process of spermatogenesis.

sphenoid (sfē'noyd) A bone that forms part of the floor of the cranium.

sphincter (sfīngk'tēr) A valve-like structure formed from circular bands of muscle. Sphincters are located around various body openings and passages.

sphygmomanometer (sfig'mō-mă-nom'ě-ter) An instrument for measuring blood pressure; consists of an inflatable cuff, a pressure bulb used to inflate the cuff, and a device to read the pressure.

spinal nerves (spī'nāl nērvs) Peripheral nerves that originate from the spinal cord.

spirillum (spī-ril'ŭm) A spiral-shaped bacterium.

spirometer (spī-rom'ě-ter) An instrument that measures the air taken in and expelled from the lungs.

spirometry (spī-rom'ě-trē) A test used to measure breathing capacity.

spleen (splēn) An abdominal organ that assists in the production and removal of blood cells.

splenectomy (sple-nek'tō-mē) Surgical removal of the spleen.

splint (splīnt) A device used to immobilize and protect a body part.

splinting catheter (splīnt'īng kath'ě-tēr) A type of catheter inserted after plastic repair of the ureter; it must remain in place for at least a week after surgery.

spores (spōrz) A resistant form of certain species of bacteria.

sprain (sprān) An injury characterized by partial tearing of a ligament that supports a joint, such as the ankle. A sprain may also involve injuries to tendons, muscles, and local blood vessels and contusions of the surrounding soft tissue.

stain (stān) In microbiology, a solution of a dye or group of dyes that imparts a color to microorganisms.

standard (stan'dārd) A specimen for which test values are already known; used to calibrate test equipment.

standardization (stan'dārd-i-zā'shŭn) The consistency of the active ingredient(s) in a supplement from batch to batch and from manufacturer to manufacturer.

standard of care (stan'dārd kār) A legal term that refers to the care that would ordinarily be provided by an average, prudent healthcare provider in a given situation.

standard precautions (stan'dārd prē-kaw'shŭnz) A combination of Universal Precautions and Body Substance Isolation guidelines; used in hospitals for the care of all patients.

stapes (stā'pēz) A small bone in the middle ear that is attached to the inner ear; also called the stirrup.

statement (stāt'měnt) Similar to an invoice; a summary of total amounts owed, including outstanding charges as well as payments received for services provided by the office.

State Unemployment Tax Act (SUTA) (stāt un-em-ploy'měnt taks akt) Some states are also governed by this act; these taxes are filed along with FUTA taxes.

statute of limitations (stach'yŭ't lim'i-tā'shŭnz) A state law that sets a time limit on when a collection suit on a past-due account can legally be filed.

stenosis (stē-nō'sis) An abnormal narrowing of a body passage.

stent (stěnt) A metal mesh tube used to hold a vessel open.

stereoscopy (ster-ē-os'kō-pē) An X-ray procedure that uses a specially designed microscope (stereoscopic, or Greenough, microscope) with double eyepieces and objectives to take films at different angles and produce three-dimensional images; used primarily to study the skull.

sterile field (ster'il fēld) An area free of microorganisms used as a work area during a surgical procedure.

sterile scrub assistant (ster'il skrüb ā-sis'tānt) An assistant who handles sterile equipment during a surgical procedure.

sterilization (ster'i-lī-zā'shŭn) The destruction of all microorganisms, including bacterial spores, by specific means.

sterilization indicator (ster'i-lī-zā'shŭn in'di-kā-tōr) A tag, insert, tape, tube, or strip that confirms that the items in an autoclave have been exposed to the correct volume of steam at the correct temperature for the correct amount of time.

sternum (stēr'nŭm) A bone that forms the front and middle portion of the rib cage; also called the breastbone or breast plate.

steroidal hormone (ster-oy'dāl hōr'mōn) A hormone derived from steroids that are soluble in lipids and can cross cell membranes very easily.

stethoscope (stēth'ě-skōp) An instrument that amplifies body sounds.

strabismus (strā-biz'mŭs) A condition that results in a lack of parallel visual axes of the eyes; commonly called crossed eyes.

strain (strān) A muscle injury that results from overexertion or overstretching.

stratum basale (strat'ŭm bā-sā'lē) The deepest layer of the epidermis of the skin.

stratum corneum (strat'ŭm kōr'nē-ŭm) The most superficial layer of the epidermis of the skin.

stratum germinativum (strā'tŭm jer-mi-nā-tī'vŭm) The deepest layer of the epidermis; also known as stratum basale.

stressor (stres'or) Any stimulus that produces stress.

stress test (stres tēst) A procedure that involves recording an electrocardiogram while the patient is exercising on a stationary bicycle, treadmill, or

stair-stepping ergometer, which measures work performed.

striations (stri-ā'shŭns) Bands produced from the arrangement of filaments in myofibrils in skeletal and cardiac muscle cells.

stroke (strōk) A condition that occurs when the blood supply to the brain is impaired. It may cause temporary or permanent damage.

stylus (stī'lŭs) A pen-like instrument that records electrical impulses on ECG paper.

subarachnoid space (sŭb-ă-rak'noyd spās) An area between the arachnoid mater and the pia mater.

subcategory (sŭb-kăt'ĭ-gôr'ē) The fourth digit added to many ICD-9 codes giving further specificity to the diagnosis.

subclinical case (sŭb-klin'ī-kāl kās) An infection in which the host experiences only some of the symptoms of the infection or milder symptoms than in a full case.

subcutaneous (subcut) (sŭb'kyŭ-tā'nē-ŭs) Under the skin.

subjective (sŭb-jĕk'tiv) Pertaining to data that are obtained from conversation with a person or patient.

subjective data (sŭb-jĕk'tiv dā'tā) Information about the patient's condition that includes thoughts, feelings, and perceptions.

subject line (sŭb'jekt līn) Optional line of two to three words that appears three lines below the inside address of a business letter.

sublingual (sŭb-ling'gwāl) Under the tongue.

sublingual gland (sŭb-ling'gwāl glānd) The smallest of the salivary glands.

submandibular gland (sŭb-man-dib'yulār glānd) The gland that is located in the floor of the mouth.

submucosa (sŭb'myŭ-kō'sā) The layer of the alimentary canal located between the mucosa and the muscular layer.

subpoena (sŭ-pē'nā) A written court order that is addressed to a specific person and requires that person's presence in court on a specific date at a specific time.

subpoena duces tecum (sŭ-pē'nā dŭ'sēz tē'kum) Latin; a legal document that requires the recipient to bring certain written records to court to be used as evidence in a lawsuit.

substance abuse (sŭb'stāns ā-byŭs') The use of a substance in a way that is not

medically approved, such as using diet pills to stay awake or consuming large quantities of cough syrup that contains codeine. Substance abusers are not necessarily addicts.

sucrase (sŭ'krās) An enzyme that digests sugars.

sudoriferous (sŭ'dŏr-if'ēr-ŭs) The sweat glands.

suffix (sŭ-fiks) A word part that comes at the end of a medical term that alters the meaning of the term.

sulci (sŭl'si) The grooves on the surface of the cerebrum.

superbill (sŭ'pĕr-bil) A form that combines the charges for services rendered, an invoice for payment or insurance copayment, and all the information for submitting an insurance claim; also known as an encounter form.

superficial (sŭ'pĕr-fish'āl) Anatomical term meaning closer to the surface of the body.

superior (sŭ-pĕr'ē-ŏr) Anatomical term meaning above or closer to the head; also called cranial.

supernatant (sŭ-per-nā'tānt) The liquid portion of a substance from which solids have settled to the bottom, as with a urine specimen after centrifugation.

supination (sŭ'pi-nā'shŭn) Turning the palm of the hand upward.

surfactant (sŭr-fak'tānt) Fatty substance secreted by some alveolar cells that helps maintain the inflation of the alveoli so that they do not collapse in on themselves between inspirations.

surgeon (sŭr'jŏn) A physician who uses hands and medical instruments to diagnose and correct deformities and treat external and internal injuries or disease.

surgical asepsis (sŭr'ji-kāl ā-sep'sis) The elimination of all microorganisms from objects or working areas; also called sterile technique.

surgical site infection (SSI) (sŭr'ji-kāl sīt in-fek'shŭn) An infection that occurs after a surgical procedure at the site of surgery.

susceptible host (sŭ-sep'ti-bĕl hōst) An individual who has little or no immunity to infection by a particular organism.

SUTA See **State Unemployment Tax Act**.

suture (sŭ'chŭr) Fibrous joint in the skull. Also, a surgical stitch made to close a wound.

swaged needle (swāj'd nē'dĕl) A suturing needle that has the suture material permanently attached to the needle.

symmetry (sim'ē-trē) The degree to which one side of the body is the same as the other.

sympathetic branch (sim'pă-thet'ik branch) A branch of the autonomic nervous system that prepares organs for fight-or-flight (stressful) situations.

symptom (simp'tŏm) A subjective, or internal, condition felt by a patient, such as pain, headache, or nausea, or another indication that generally cannot be seen or felt by the doctor or measured by instruments.

synaptic knob (si-nap'tik nŏb) The end of the axon branch.

synaptic space (si-nap-'tik spās) The space between the axon of one neuron and the dendrite of the next.

synergist (sĭm'ər-jist) Muscle that helps the prime mover by stabilizing joints.

synovial (sin-ŏ'vē-āl) A type of joint, such as the elbow or knee, that is freely moveable.

systemic circuit (sis-tem'ik sĭr'kŭt) The route that blood takes from the heart through the body and back to the heart.

systemic circulation (sis-tem'ik sĭr'kyŭ-lā'shŭn) The circulation of blood through the arteries, capillaries, and veins of the general system, from the left ventricle to the right atrium.

systemic lupus erythematosus (SLE) (sis-tem'ik lŭ'pŭs ěr-ith'ē-mă-tŏ'sŭs) An autoimmune disorder in which a person produces antibodies that target the person's own cells and tissues.

systolic pressure (sis-tol'ik presh'ŭr) The blood pressure measured when the left ventricle of the heart contracts.

tab (tăb) A tapered rectangular or rounded extension at the top of a file folder.

Tabular List (tab'yŭ-lār list) One of two ways that diagnoses are listed in the ICD-10. In the Tabular List, the diagnosis codes are listed in numeric order with additional instructions.

tachycardia (tak'i-kahr'dē-ă) Rapid heart rate, generally in excess of 100 beats per minute.

tachypnea (tăk'ĕp-nē-ă) Abnormally rapid breathing.

targeted résumé (tahr'gĕt-ed rĕ'zŭm-ă) A résumé that is focused on a specific job target.

tarsals (tahr'sälz) Bones of the ankle.

taste bud (täst būd) A structure that is made of taste cells (a type of chemoreceptor) and supporting cells.

tax liability account (taks lī'ä-bil'ī-tē ä-kownt') Money withheld from employees' paychecks and held in a separate account that must be used to pay taxes to appropriate government agencies.

teamwork (tēm'-wōrk) Working with others in the best interest of completing the job.

telecommunications device for the deaf (TDD) (tel'ē-kō-myū'ni-kā'shūns dē-vīs' def) Telephone accessory that transmits and receives text over standard telephone lines.

telephone triage (tēl'ē-fōn'trē'ahzh) A process of determining the level of urgency of each incoming telephone call and how it should be handled.

teletherapy (tel'ē-thār'ä-pē) A radiation therapy technique that allows deeper penetration than brachytherapy; used primarily for deep tumors.

teletype (TTY) device (tēl'ē-tīp) A specially designed telephone that looks very much like a laptop computer with a cradle for the receiver of a traditional telephone. It is used by the hearing impaired to type communications onto a keyboard.

telophase (tel'ō-fāz) The final stage of mitosis; chromosomes reach the centrioles and the division creating two cells, each with a complete set of chromosomes, is completed.

template (tem'plāt) A guide that ensures consistency and accuracy.

temporal (tem'pōr-äl) Bones that form the lower sides of the skull.

temporal mandibular joint (TMJ) (tem'pōr-äl man-dib'yū-lär joynt) The location where the mandible attaches to the temporal bone.

temporal scanner (tem'pōr-äl skan'ēr) An instrument used to measure the body temperature by scanning the temporal artery in the forehead.

tendon (ten'dōn) A cord-like, fibrous tissue that connects muscle to bone.

tendonitis (ten'dō-nī'tis) Inflammation of a tendon.

terminal (tēr'mi-näl) Fatal.

terminal digit (tēr'mi-näl dij'it) A small group of two to three numbers at the end of a patient number that is used as an identifying unit in a filing system.

testes (tēs'tēz) The primary organs of the male reproductive system. Testes produce the hormone **testosterone**.

testosterone (tēs-tōs'tē-rōn) A hormone produced by the testes that maintains the male reproductive structures and male characteristics such as deep voice, body hair, and muscle mass.

tetanus (tet'ä-nūs) A disease caused by *Clostridium tetani* living in the soil and water; more commonly called lockjaw.

thalamus (thal'ä-mūs) Structure that acts as a relay station for sensory information heading to the cerebral cortex for interpretation; a subdivision of the diencephalon.

thalassemia (thal'ä-sē'mē-ä) An inherited form of anemia with a defective hemoglobin chain causing microcytic (small), hypochromic (pale), and short-lived red blood cells.

therapeutic team (thār'ä-pyū'tik tēm) A group of physicians, nurses, medical assistants, and other specialists who work with patients dealing with chronic illness or recovery from major injuries.

therapeutic touch (thār'ä-pyū'tik tüch) The use of touch to detect and correct a person's energy fields, thus promoting healing and health.

thermography (ther-mog'rä-fē) A radiologic procedure in which an infrared camera is used to take photographs that record variations in skin temperature as dark (cool areas), light (warm areas), or shades of gray (areas with temperatures between cool and warm); used to diagnose breast tumors, breast abscesses, and fibrocystic breast disease.

thermometer (ther-mom'ē-ter) An instrument, either electronic or disposable, that is used to measure body temperature.

thermotherapy (ther'mō-thār'ä-pē) The application of heat to the body to treat a disorder or injury.

third-party check (thīrd-pahr'tē chek) A check made out to one recipient and given in payment to another, as with one made out to a patient rather than the medical practice.

third-party payer (thīrd-pahr'tē pā'ēr) A health plan that agrees to carry the risk of paying for patient services.

thoracocentesis (thōr'ä-kō-sen-tē'sis) Medical procedure where a sterile needle is introduced into the chest to remove fluid and pus.

thoracostomy (thōr'ä-kos'tō-mē) The surgical insertion of a chest tube to provide continuous drainage of the thoracic (chest) cavity.

thorax (thō'raks) The chest cavity.

thrombocytes (throm'bō-sīts) See **platelets**.

thrombophlebitis (thrōm'bō-flē-bī'tis) A medical condition that most commonly occurs in leg veins when a blood clot and inflammation develop.

thrombus (thrōm'būs) A blood clot that forms on the inside of an injured blood vessel wall.

thymosin (thī'mō-sin) A hormone that promotes the production of certain lymphocytes.

thymus (thī'mūs) A gland that lies between the lungs. It secretes a hormone called thymosin.

thyroid cartilage (thīroyd kahr'ti-lāj) The largest cartilage in the larynx. It forms the anterior wall of the larynx.

thyroid gland (thīroyd gland) An endocrine gland, consisting of irregularly spheroid follicles, lying in front and to the sides of the upper part of the trachea, in a horseshoe shape, with two lateral lobes connected by a narrow central portion, the isthmus; occasionally an elongated offshoot, the pyramidal lobe, passes upward from the isthmus in front of the trachea. It is supplied by branches from the external carotid and subclavian arteries, and its nerves are derived from the middle cervical and cervicothoracic ganglia of the sympathetic system. It secretes thyroid hormone and calcitonin.

thyroid hormone (thīroyd hōr'mōn) A hormone produced by the thyroid gland that increases energy production, stimulates protein synthesis, and speeds up the repair of damaged tissue.

thyroid-stimulating hormone (TSH) (thīroyd-stīm'yū-lāt-ing hōr'mōn) A hormone that stimulates the thyroid gland to release its hormone.

tibia (tī'bē-ä) The medial bone of the lower leg; commonly called the shin bone.

tickler file (tik'lēr fīl) A reminder file for keeping track of time-sensitive obligations.

timed urine specimen (tīmd yūr'in spes'i-mēn) A specimen of a patient's urine collected over a specific time period.

time management (tīm man'āj-mēnt) Utilizing time in an effective manner to accomplish the desired results.

time-specified scheduling (tīm spēš'ī-fīd sked'jūl-ing) A system of scheduling where patients arrive at regular, specified intervals, assuring the practice a steady stream of patients throughout the day.

tinea (tīn'ē-ă) A fungal infection.

tinnitus (tīn'i-tūs) An abnormal ringing in the ear.

tissue (tish'ū) A structure that is formed when cells of the same type organize together.

T lymphocyte (tē lim'fō-sīt) A type of nongranular leukocyte that regulates immunologic response; includes helper T cells and suppressor T cells.

tonsils (ton'silz) Sets of lymphoid tissue in and around the oral cavity. The three sets are the pharyngeal tonsils (adenoids), palatine tonsils, and lingual tonsils.

tonometer (tō-nom'ē-tēr) An instrument for determining pressure or tension, especially determining ocular tension.

topical (tōp'ī-kāl) Applied to the skin.

tort (tōrt) In civil law, a breach of some obligation that causes harm or injury to someone.

torticollis (tōr'ti-kol'is) A muscular disease causing a cervical deformity in which the head bends toward the affected side while the chin rotates to the opposite side.

touchpad (tūch pād) A type of pointing device common to laptop and notebook computers that directs activity on the computer screen by positioning a pointer or cursor on the screen. It is a small, flat device or surface that is highly sensitive to touch.

touch screen (tūch skrēn) A type of computer monitor that acts as an intake device, receiving information through the touch of a pen, wand, or hand directly to the screen.

tourniquet (tūr'ni-kēt) An instrument for temporarily arresting the flow of blood to or from a distal part by pressure applied with an encircling device.

tower case (tou'ēr kās) A vertical housing for the system unit of a personal computer.

toxicology (tōk'sī-kōl'ō-jē) The study of poisons or poisonous effects of drugs.

TPO See **treatment, payments, and operations**.

trachea (trā'kē-ă) The part of the respiratory tract between the larynx and the

bronchial tree that is tubular and made of rings of cartilage and smooth muscle; also called the windpipe.

trackball (trāk-bawl) A pointing device with a ball that is rolled to position a pointer or cursor on a computer screen. It can be directly attached to the computer or can be wireless.

tracking (trāk'ing) Watching for changes in spending so as to help control expenses.

traction (trak'shūn) The pulling or stretching of the musculoskeletal system to treat dislocated joints, joints afflicted by arthritis or other diseases, and fractured bones.

trade name (trād nām) A drug's brand, or proprietary, name.

traditional Chinese medicine (TCM) (trā-dī'shūn-ăl chī-nēz' med'i-sin) An ancient system of medicine originating in China that involves herbal and animal source preparations to treat illness. TCM includes various treatments such as acupuncture and acupressure.

transcription (trān-skrīp'shūn) The transforming of spoken notes into accurate written form.

transcutaneous absorption (tranz'kyū-tā-nē-ūs āb-sōrp'shūn) Entry (as of a pathogen) through a cut or crack in the skin.

transdermal (trans-der'māl) A type of topical drug administration that slowly and evenly releases a systemic drug through the skin directly into the bloodstream; a transdermal unit is also called a patch.

transfer (trāns'fēr) To give something, such as information, to another party outside the doctor's office.

transmission-based precautions (trans-mish'ūn-bāsd prē-kaw'shūnz) CDC guidelines that supplement standard precautions when caring for patients with suspected or confirmed infection. The three types of transmission-based precautions are contact, droplet, and airborne precautions.

transurethral resection of prostate (trans'yūr-ē'thrāl rē-sek'shūn pros'tāt) Removal of the prostate through the urethra.

transverse (trans-vērs') Anatomical term that refers to the plane that divides the body into superior and inferior portions.

transverse colon (trans-vērs' kō'lōn)

The segment of the large intestine that crosses the upper abdominal cavity between the ascending and descending colon.

traveler's check (trāv'ēl-rz chēk) A check purchased and signed at a bank and later signed over to a payee.

treatment, payments, and operations (TPO) (trēt'mēnt pā-mēnt op-ēr-ā'shūns) The portion of HIPAA that allows the provider to use and share patient healthcare information for treatment, payment, and operations (such as quality improvement).

triage (trē'ahzh) To assess the urgency and types of conditions patients present as well as their immediate medical needs.

TRICARE (trī'kār) A program that provides healthcare benefits for families of military personnel and military retirees.

trichinosis (trik-i-nō'sis) A disease caused by a worm that is usually ingested from undercooked meat.

tricuspid valve (trī-kūs'pid vālv) A heart valve that has three cusps and is situated between the right atrium and the right ventricle.

triglycerides (trī-glīs'ēr-idz) Simple lipids consisting of glycerol (an alcohol) and three fatty acids.

trigone (trī'gōn) The triangle formed by the openings of the two ureters and the urethra in the internal floor of the bladder.

triple check (trip'ēl chēk) The process of checking a medication three times before administering it. First check is when you take it from the storage container and match it to the MAR; second check is when you prepare the medication; third check is before you close the container or just before you administer the medication.

troubleshooting (trüb'ēl-shū'ting)

Trying to determine and correct a problem without having to call a service supplier.

Truth in Lending Statement (trūth lend-ing stāt'mēnt) A written description of the agreed terms of payment between the patient and medical practice when payment will be made in more than four installments.

trypsin (trip'sin) A pancreatic enzyme that digests proteins.

TSH See **thyroid-stimulating hormone**.

TTY device See **teletype device**.

tubular reabsorption (tū'byū-lār re-ab-sōrp'shūn) The second process of urine formation in which the glomerular filtrate flows into the proximal convoluted tubule.

tubular secretion (tū'byū-lār sī-krē'shūn) The third process of urine formation in which substances move out of the blood in the peritubular capillaries into renal tubules.

tutorial (tūt-or'rē-ēl) A small program included in a software package designed to give users an overall picture of the product and its functions.

tympanic membrane (tim-pān'ik mēm'brān) A fibrous partition located at the inner end of the ear canal and separating the outer ear from the middle ear; also called the eardrum.

tympanic thermometer (tim-pan'ik ther-mom'ē-ter) A type of electronic thermometer that measures infrared energy emitted from the tympanic membrane.

ulna (ūl'nā) The medial bone of the lower arm.

ultrasonic cleaning (ūl'trā-sōn'ik klēn'ing) A method of sanitization that involves placing instruments in a cleaning solution in a receptacle that generates sound waves through the cleaning solution, loosening contaminants. Ultrasonic cleaning is safe for even very fragile instruments.

ultrasound (ūl'trā-sownd) The noninvasive therapeutic or diagnostic use of very high frequency sound waves for examination of internal body structures.

umami (ū-mom'ē) Savory taste produced by glutamic acid (monosodium glutamate), recognized as the fifth taste sensation.

umbilical cord (ūm-bil'i-kāl kōrd) The rope-like connection between the fetus and the placenta. It contains the umbilical blood vessels.

unbundling (ūn-būnd'ling) Use of several *Current Procedural Terminology* codes for a service when one inclusive code is available.

underbooking (ūn'dēr buk'ing) Leaving large, unused gaps in the doctor's schedule; this approach does not make the best use of the doctor's time.

uniform donor card (yū'ni-fōrm dō'nōr kahr'd) A legal document that states a person's wish to make a gift upon death of one or more organs for medical

research, organ transplants, or placement in a tissue bank.

unit (yū'nit) A part of an individual's name or title, described in indexing rules.

unit price (yū'nit prīs) The total price of a package divided by the number of items that comprise the package.

universal precautions (yū'ni-vēr'sāl prē-kaw'shūnz) Specific precautions required by the Centers for Disease Control and Prevention (CDC) to prevent healthcare workers from exposing themselves and others to infection by blood-borne pathogens.

unsaturated fats (ūn-sāch'ūr-āt-ēd fats) Fats, including most vegetable oils, that is usually liquid at room temperature and tends to lower blood cholesterol.

upcoding (ūp'kōd-ing) Coding to a higher level of service than that provided to obtain higher reimbursements.

upper respiratory (tract) infection (ūp'ēr res'pir-ā-tōr-ē trakt in-fek'shūn) The common cold. (29)

urea (yūr-ē'ā) Waste product formed by the breakdown of proteins and nucleic acids.

ureters (yūr'ē-tērz) Long, slender, muscular tubes that carry urine from the kidneys to the urinary bladder.

urethra (yūr-ē'thrā) The tube that conveys urine from the bladder during urination.

uric acid (yūr'ik as'id) Waste product formed by the breakdown of proteins and nucleic acids.

urinalysis (yūr'in-al'i-sis) The physical, chemical, and microscopic evaluation of urine to obtain information about body health and disease.

urinary catheter (yūr'i-nar-ē kath'ē-tēr) A sterile plastic tube inserted to provide urinary drainage.

urinary pH (yūr'i-nar-ē) A measure of the degree of acidity or alkalinity of urine.

urine culture (yūr'in kŭl'chŭr) A laboratory test in which urine is placed on a growth medium and bacteria are allowed to grow for 24 to 48 hours. Any large growths of bacteria are then identified. Urine cultures are often followed by a sensitivity or susceptibility test to determine which antibiotic will be most effective against the bacteria.

urine specific gravity (yūr'in spē-sif'ik grav'i-tē) A measure of the

concentration or amount (total weight) of substances dissolved in urine.

urobilinogen (yūr-ō-bī-lin'ō-jen) A colorless compound formed by the breakdown of hemoglobin in the intestines. Elevated levels in urine may indicate increased red blood cell destruction or liver disease, whereas lack of urobilinogen in the urine may suggest total bile duct obstruction.

urologist (yūr-ol'ō-jist) A specialist who diagnoses and treats diseases of the kidney, bladder, and urinary system.

use (ūs) The sharing, employing, applying, utilizing, examining, or analyzing of individually identifiable health information by employees or other members of an organization's workforce.

uterus (yū'tēr-ŭs) A hollow, muscular organ that functions to receive an embryo and sustain its development; also called the womb.

utilization review (UR) (yū'ti-lī-zā'shūn rē-vyū') The process of reviewing medical care in individual cases to be sure that all services provided were medically necessary and that there was appropriate use of medical resources; performed by medical peers and used as a cost control measure by managed care organizations.

uvula (ū'vyū-lā) The part of the soft palate that hangs down in the back of the throat.

uvulotomy (ū'vyū-lot'ō-mē) Surgical procedure removing all or part of the uvula of the soft palate.

vaccine (vāk-sēn') A preparation made from microorganisms and administered to a person to produce reduced sensitivity to or increased immunity to, an infectious disease.

vagina (vā-jī'nā) A tubular organ that extends from the uterus to the labia.

vaginal introitus (vaj'i-nāl in-trō'i-tŭs) The vaginal os, or orifice. The opening of the vagina to the outside of the body.

vaginitis (vaj-i-nī'tis) Inflammation of the vagina characterized by an abnormal vaginal discharge.

varicose veins (vār'i-kōs vānz) Distended veins that result when vein valves are destroyed and blood pools in the veins, causing these veins to dilate.

vas deferens (vas def'ēr-enz) A tube that connects the epididymis with the urethra and that carries sperm.

vasectomy (vas-ek'tō-mē) A male sterilization procedure in which a section of each vas deferens is removed.

vasoconstriction (vā-sō-kōn-strīk'shūn) The constriction of the muscular wall of an artery to increase blood pressure.

vasodilation (vā-sō-dī-lā'shūn) The widening of the muscular wall of an artery to decrease blood pressure.

V code (vē kōd) A code used to identify encounters for reasons other than illness or injury, such as annual checkups, immunizations, and normal childbirth.

vector (vek'tōr) A living organism, such as an insect, that carries microorganisms from an infected person to another person.

venipuncture (ven'i-pūngk'shūr) The puncture of a vein, usually with a needle, for the purpose of drawing blood.

venoscope (vē'no-skōp) An instrument that helps visualize a vein; LED lights illuminate the subcutaneous tissue to highlight the veins.

ventilation (ven'ti-lā'shūn) Moving air into and out of the lungs; also called breathing.

ventral (vēn'trāl) See **anterior**.

ventral root (ven'trāl rūt) A portion of the spinal nerve that contains axons of motor neurons only.

ventricle (ven'tri-kēl) Interconnected cavities in the brain filled with cerebrospinal fluid.

ventricular fibrillation (VF) (ven-trīk'yū-lār fib'ri-lā'shūn) An abnormal heart rhythm that is the most common cause of cardiac arrest.

verbalizing (vūr'bā-līz'ing) Stating what you believe the patient is suggesting or implying.

vermiform appendix (vē'r-mi-fōrm ā-pen'diks) A structure made mostly of lymphoid tissue and projecting off the cecum. It is commonly referred to as simply the appendix.

vertical file (vē'r'ti-kāl) A filing cabinet featuring pull-out drawers that usually contain a metal frame or bar equipped to handle letter- or legal-sized documents in hanging file folders.

vertigo (vē'r'ti-gō) Dizziness.

vesicles (vēs'ī-kēlz) Small sacs within the synaptic knobs that contain chemicals called neurotransmitters.

vestibule (ves'ti-byūl) The area in the inner ear between the semicircular canals and the cochlea.

VF See **ventricular fibrillation**.

vial (vī'āl) A small glass bottle with a self-sealing rubber stopper.

vibrio (vib'rē-ō) A comma-shaped bacterium.

virtual private network (VPN) (vir'chū-āl prī'vāt net'wōrk) These are used to connect two or more computer systems.

virulence (vir'yū-lēns) A microorganism's disease-producing power.

virus (vī'rūs) One of the smallest known infectious agents, consisting only of nucleic acid surrounded by a protein coat; can live and grow only within the living cells of other organisms.

visceral pericardium (vis'er-āl per-i-kahr'dē-ūm) The innermost layer of the pericardium that lies directly on top of the heart; also known as the epicardium.

visceral peritoneum (vis'ēr-āl per-i-tō-nē'ūm) Also known as the serosa, the outermost layer of the abdominal organs that secretes serous fluid to keep the organs from sticking to each other.

visceral smooth muscle (vis'ēr-āl smūth mūs'ēl) A type of smooth muscle containing sheets of muscle that closely contact each other. It is found in the walls of hollow organs such as the stomach, intestines, bladder, and uterus.

viscosity (vis-kos'i-tē) Thickness.

vitamin (vīt'ā-min) Organic substance that is essential for normal body growth and maintenance and resistance to infection.

vitreous humor (vīt'rē-ūs hyū'mōr) A jelly-like substance that fills the part of the eye behind the lens and helps the eye keep its shape.

voice mail (voys māl) An advanced form of answering machine that allows a caller to leave a message when the phone line is busy.

void (voyd) A term used to describe something that is not legally enforceable.

volume (vol'yūm) The amount of space an object, such as a drug, occupies.

vomer (vō'mēr) A thin bone that divides the nasal cavity.

voucher check (vow'chēr chēk) A business check with an attached stub, which is kept as a receipt.

VPN See **virtual private network**.

vulva (vūl'vā) External female genitalia.

vulvovaginitis (vul-vō-vaj'i-nī'tis) Inflammation of the external female genitalia and vagina.

walk-in (wōk'in) A patient who arrives without an appointment.

WAN (wān) See **wide-area network**.

warranty (wōr'ān-tē) A contract that specifies free service and replacement of parts for a piece of equipment during a certain period, usually a year.

warts (wōrts) Flesh-colored skin lesions with distinct, round borders that are raised and often have small, finger-like projections; also called verruca.

wave scheduling (wāv sked'jūl-ing) A system of scheduling in which the number of patients seen each hour is determined by dividing the hour by the length of the average visit and then giving that number of patients appointments with the doctor at the beginning of each hour.

weight (wāt) The product of the force of gravity, defined internationally as 9.81 (m/sec)/sec, × the mass of the body.

wellness (wēl'nēs) A philosophy of life and personal hygiene that views health as not merely the absence of illness but the fullest realization of one's physical and mental potential, as achieved through positive attitudes, fitness training, a diet low in fat and high in fiber, and the avoidance of unhealthful practices.

Western blot test (wes'tērn blōt tēst) A blood test used to confirm enzyme-linked immunosorbent assay (ELISA) test results for HIV infection.

wet mount (wēt mount) A preparation of a specimen in a liquid that allows the organisms to remain alive and mobile while they are being identified.

white matter (hwīt māt'ēr) The outer tissue of the spinal cord that is lighter in color than gray matter. It contains myelinated axons.

whole blood (hōl blūd) The total volume of plasma and formed elements, or blood in which the elements have not been separated by coagulation or centrifugation.

whole-body skin examination (hōl-bōd'ē skīn eg-zam'i-nā'shūn) An examination of the visible top layer of the entire surface of the skin, including the scalp, genital area, and areas between the toes, to look for lesions, especially suspicious moles or precancerous growths.

whole foods (hōl fūdʒ) Foods that have little or no processing before they are eaten.

wide-area network (WAN) (wīd ār'ē-ā net'wōrk) A computer network in which the computers connected may be far apart, generally having a radius of half a mile or more.

Wood's light examination (wudz līt eg-zam'i-nā'shūn) A type of dermatologic examination in which a physician inspects the patient's skin under an ultraviolet lamp in a darkened room.

word root (wōrd rūt) The base meaning of a medical term.

work ethic (wōrk eth'ik) A set of values of hard work held by employees.

work practice controls (wōrk prak'tis kōn-trōzl') Controlling workplace injuries by altering the way a task is performed.

work quality (wōrk kwahl'i-tē) Striving for excellence in doing the job; pride in one's performance.

World Health Organization (WHO) (wōrld helth ōr'gān-ī-zā'shūn) A unit of the United Nations devoted to international health problems.

write-it-once (pegboard) system (rīt it wūns pēg-bōrd' sis'tēm) A manual bookkeeping system where the daily log has prepunched holes on the right or left

side of the log. Prepunched charge sheets (of NCR paper) are placed in designated areas on top of the day sheet, which has been placed on the pegboard. The patient ledger card is placed between the day sheet and the charge sheet and an entry is made; it appears on all three documents at the same time.

written-contract account (rē'ten kōn'trākt ā-kownt) An agreement between the physician and patient stating that the patient will pay a bill in more than four installments.

X12 837 Health Care Claim (hēlth kār klām) An electronic claim transaction that is the HIPAA Health Care Claim or Equivalent Encounter Information ("HIPAA claim").

xeroradiography (zē'rō-rā'dē-og'rā-fē) A radiologic procedure in which X-rays are developed with a powder toner, similar to the toner in photocopiers, and the X-ray image is processed on specially treated xerographic paper; used to diagnose breast cancer, abscesses, lesions, or calcifications.

xiphoid process (zī'fōyd pros'es) The lower extension of the breastbone; the cartilaginous tip of the sternum.

yeast (yēst) A fungus that grows mainly as a single-celled organism and reproduces by budding.

yoga (yō'gā) A series of poses and breathing exercises that provide awareness of the unity of the whole being. The practice of yoga also increases flexibility and strength.

yolk sac (yōk sāk) The sac that holds the materials for the nutrition of the embryo.

Zip drive (zip drīv) A high-capacity disk drive developed by Iomega®. Zip drives can hold 100 to 750 MB of data. They are durable and relatively inexpensive. They may be used for backing up hard disks and transporting large files.

zona pellucida (zō'nā pe-lū'sid-ā) A layer that surrounds the cell membrane of an egg.

Z-track method (zē'trāk mēth'ōd) A technique used when injecting an intramuscular (IM) drug that can irritate subcutaneous tissue; involves pulling the skin and subcutaneous tissue to the side before inserting the needle at the site, creating a zigzag path in the tissue layers that prevents the drug from leaking into the subcutaneous tissue and causing irritation.

zygomatic (zī'gō-mat'ik) The bones that form the prominence of the cheeks.

zygote (zī'gōt) The cell that is formed from the union of the egg and sperm.

Index

Page numbers in **boldface** indicate figures. Page numbers followed by b indicate box features, p procedures, and t tables, respectively.
