7. Prepare or, if using a computerized program, print a summary of charges, receipts, and disbursements every month, quarter, or year, as directed. Double-check all entries and calculations from the monthly summary before posting them to the quarterly summary. Also, double-check the entries and calculations from the quarterly summary before posting them to the yearly summary.

RATIONALE: *Double-checking all entries ensures that mistakes are found and corrected as soon as possible.*

PROCEDURE 20-2 Using the Superbill as Bill/Receipt

WORK // DOC

Procedure Goal: To complete a superbill accurately for use as the patient's first bill or receipt

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Superbill, patient ledger card, patient information sheet, fee schedule, pen

Method:

1. From the patient ledger card and information sheet, fill in the patient data, such as name, sex, date of birth, and insurance information.
2. Fill in the date of service. If there are multiple practice locations, circle the location where the service is taking place.
3. Attach the superbill to the patient's medical record and give them both to the practitioner.

RATIONALE: *The practitioner must have the superbill to enter the services performed during the visit.*

4. At the end of the visit, accept the completed superbill from the patient. Make sure that the practitioner has indicated the procedures performed and an appropriate diagnosis for each.

RATIONALE: *The diagnosis ensures medical necessity for the insurance carrier to allow for payment.*

5. If the practitioner has not already recorded the charges, refer to the fee schedule for procedures that are marked. Then fill in the charges next to those procedures.

RATIONALE: *Each procedure must have a charge for accurate billing.*

6. In the appropriate blanks, list the total charges for the visit and the previous balance (if any).
7. Calculate the subtotal.
8. Fill in the amount and type of payment (cash, check, money order, debit or credit card) made by the patient during this visit.

RATIONALE: *This information ensures accurate posting to the patient's account.*

9. Calculate and enter the new balance.
10. If not already on file, have the patient sign the authorization-and-release section of the superbill.
RATIONALE: *Without this signature, there is no authorization to share information with the insurance carrier, nor is there agreement for the payer to pay the service provider directly for the services provided.*
11. Keep a copy of the superbill for the practice records. Give the original to the patient along with one copy to file with the insurer.

PROCEDURE 20-3 Posting a Nonsufficient Funds (NSF) Check

WORK // DOC

Procedure Goal: To post a nonsufficient funds (NSF) check amount and any applicable fees to the patient's account

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Computer, returned check, patient ledger, calculator (optional), daily log sheet

Method:

1. Locate the patient's account on the computer, or pull the patient's ledger card for manual processes.

RATIONALE: *You must be sure that you have the correct patient (account) to record the NSF check.*

2. Use your medical facility code for NSF check (if used). Using today's date, create a new charge log for the patient. Use the code and the description *Check returned by bank* in the description column.

3. In the payment/adjustment column, place the amount of the check in parentheses to indicate that the amount is debited as an *adjustment*. Add the amount of the returned check to the old balance and enter it in the *current balance* column.

RATIONALE: *This negative payment/adjustment will increase the patient's amount due by the amount of the NSF check. The parentheses remind you to add the payment to the balance, instead of subtracting it as you usually would do.*

4. On the next line, also using today's date, enter the medical facility's code for the NSF charge allowed by the office. Enter the charge amount in the *charge column* and add this amount to the patient's current balance.

RATIONALE: *The office has the right to charge the patient for the inconvenience of dealing with an NSF check.*

PROCEDURE 20-4 Processing a Payment Resulting in a Credit Balance

WORK // DOC

Procedure Goal: To process a payment that results in a credit balance on the patient's account

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Daily log or day sheet, patient ledger card, computer, calculator, patient explanation of benefits (EOB) or remittance advice (RA) if applicable, and patient or insurance payment

Method:

1. Locate the patient's account in the computer, or pull the patient's ledger card for paper-based systems.

RATIONALE: *Patient financial records are legal documents, so you must be sure to post financial information to the correct account.*

2. Post the total amount of the payment received to the patient's account by writing (or keying) the remittance amount in the paid column.

3. Subtract the payment amount from the previous balance and insert the new balance in the balance column. If the balance created is a *credit* balance, insert the figure in the current balance column within parentheses.

RATIONALE: *Inserting figures in parentheses tells the office staff that the balance is owed by the practice (credit balance), not to the practice (debit balance).*

4. Review the account thoroughly, checking to see if any more receipts are expected on the patient's account.

RATIONALE: *Some patients have multiple insurance plans and more than one insurance payment may be expected on the account.*

5. If a credit balance is verified, adjust the credit balance off the patient's account by issuing a refund (see Procedure 20-5).

PROCEDURE 20-5 Processing Refunds to Patients

WORK // DOC

Procedure Goal: To process a patient refund due to a credit balance

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Payment (check), ledger card, computer, calculator, remittance advice (RA) or explanation of benefits (EOB) if applicable

Method:

1. Calculate and determine the amount to be refunded (from Procedure 20-4). If the amount to be refunded is determined by the EOB or RA, verify the amount listed.

RATIONALE: *If the patient made a payment and the insurance plan directs the office to return the patient's payment, that amount must be refunded to the patient.*

2. Record the check number and amount in the disbursements journal or checkbook and write a check to the patient for the amount to be refunded.

RATIONALE: *Always record transactions in the checkbook first so that you never forget this step.*

3. Ask the practitioner or business manager to sign the check so that it can be given or mailed to the patient.

4. Post the refund as a negative payment (credit) to the patient's ledger card or to the patient's account if a computerized system is being used. Using parentheses around the figure is a common way to record the credit.

5. Make a copy of the check, retaining a copy in the patient's financial record. Give or mail the check to the patient. If the check is being mailed, be sure to verify the patient's address prior to mailing and utilize certified return receipt mail to be sure the patient receives the check.

PROCEDURE 20-6 Preparing an Age Analysis

WORK // DOC

Procedure Goal: To create and examine an age analysis of practice accounts

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Computer, patient accounts, ledger cards (if a manual system is used), accounts receivable age analysis form or template (Figure 20-10), policies and procedures manual, pen

Method:

1. Using the reporting section of your billing computer program, create an age analysis report for patients and insurance companies. This also can be done manually by pulling patient ledger cards, noting balances due and dates of last payments. Use Figure 20-10 as a guide to create a spreadsheet for your findings.

RATIONALE: *If the office billing is computerized, pulling an aging report from the system is efficient and reliable.*

2. Review the accounting report. Check the report—highlight each account for proposed actions according to your office policy.
RATIONALE: *Efforts to collect outstanding accounts become more urgent as accounts age and it becomes more difficult to collect the outstanding balance.*
3. Mark the accounts that are under 31 days as “No action to be taken at this time.”
RATIONALE: *Accounts of this age are considered current.*
4. Bills that are unpaid at more than 31 days should be marked as “Contact or follow up with insurance company.”
RATIONALE: *Patients frequently wait for the insurance carrier to pay its portion before they pay the patient balance.*
5. Accounts that are 31–60 days old should be marked according to your office policy. An initial phone call may be made inquiring as to payment arrangements.
RATIONALE: *The older an account becomes, the more difficult it is to collect. These accounts are at “prime time” to be collected.*
6. Accounts that are 61–90 days old should be marked according to your office policy. Make notations such as “Account Past Due.” A follow-up phone call and/or more insistent statement message letter for payment may be in order.

- RATIONALE:** *Collecting accounts aged less than 91 days have a better success rate than those that are older.*
7. Accounts that are 91–120 days old should be marked according to your office policy. A last phone call to attempt discussing the account and more insistent collection statement/letter should be sent.
8. For accounts older than 120 days, make sure you review previous collection attempts. At this point, after discussion with the physician, a letter stating the account will be turned over to the collection agency will take place with a specific date listed in the letter. This letter should be mailed by certified, return receipt mail.
RATIONALE: *After 120 days without a payment, it is unlikely the patient will pay the bill without a more aggressive course of action.*
9. Record all actions that have been taken beside each account.
RATIONALE: *This diary provides a written record of all attempts to collect the debt.*
10. Finally, write follow-up letters to patients and document any agreements that you and the patient have discussed via telephone. Be sure to keep a copy of any correspondence mailed to the patient in the financial record.
RATIONALE: *All documentation will be necessary, should any legal action be taken regarding this debt.*

PROCEDURE 20-7 Referring an Account to a Collection Agency and Posting the Payment from the Agency

Procedure Goal: To follow the correct procedure in turning an account over to a collection agency and posting the payment from them when received

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Computer, patient accounts, ledger cards (if a manual system is used), patient’s financial record containing demographic information, collection agency’s phone number, pen

Method:

1. Make sure all attempts that have been made to collect the debt per office policy have been documented, including the return receipt from the letter sent to the patient stating that the account would be turned over to the collection agency by a specific date (today).
RATIONALE: *To avoid charges of harassment, once a threat of collection proceedings has been made, the account must be turned over on the specified date.*
2. Verify that the following information is in the patient’s financial file to be turned over to the collection agency:
 - Last known phone number and address for the patient
 - Employer (if any) name and phone number
 - Name of spouse, if applicable
 - Total amount of debt, with last payment amount and date
 - If there has been no payment, the last date a service was provided
 - Description of office actions to collect debt
 - Any patient response to those actions

- RATIONALE:** *This information is required by the collection agency prior to taking over the account.*
3. Place a call to the agency, identifying yourself and the office, and explain you are calling to turn accounts over to them.
4. For each account to be turned over, supply the information listed in step 2.
5. When a payment arrives from the agency, each account will be identified with the total amount of the debt collected. The agency will also deduct its fee from this amount.
RATIONALE: *The agency will collect its fee up front from the payment received per contracted agreement with the practice.*
6. When posting the payment, post the actual amount of the payment sent to the office from the collection agency to the patient’s account, not the full amount of the payment made by the patient.
RATIONALE: *The agency kept a portion of the payment as its fee; it will not be posted to the patient’s account.*
7. Make an adjustment (write-off) on the patient’s account in the amount kept by the agency as its fee.
RATIONALE: *You cannot add the fee charged by the collection agency to the patient’s account. It is a “cost of doing business.”*
8. Subtract both the payment and the adjustment from the patient’s balance. If the payment is noted by the agency as being the full payment on the account, the payment and adjustment should result in a zero balance on the patient’s account.

PROCEDURE 20-8 Completing a Truth in Lending Statement (Agreement)

WORK // DOC

Procedure Goal: To create an accurate and complete Truth in Lending Statement

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Computer, paper, patient financial record, Truth in Lending patient letter (sample), Truth in Lending Statement, name of the procedure or service to be financed, total cost of procedure or service to be financed, amount of down payment, number of payments, amount of each payment, date of month for each payment, pen

Method:

1. Create a document (or use a template) similar to that of Figure 20-12 to use as the Truth in Lending Statement.
2. Make sure the following information is included:
 - Patient name and address
 - Price for service or procedure
 - Amount of down payment received
 - Unpaid balance
 - Amount financed
 - Finance charge (if applicable)
 - Finance charge as a percentage rate (if applicable)

- Total amount to be financed
 - Number of payments and the amount of each
 - Date payments are due, including final payment date
3. Once the template is completed, fill in the information for the patient's agreement. Make calculations carefully and check your work.

RATIONALE: *For the Truth in Lending Statement to be valid, all information must be included and accurate.*
 4. After going over the statement with the patient, have the patient sign and date the agreement.

RATIONALE: *Without the patient's signature the agreement is not valid.*
 5. Give a copy of the signed agreement to the patient and keep a copy in the patient's financial record for future reference.
 6. If desired, a master document, such as that found in Figure 20-13, may be created outlining the agreement and listing the actual date and payment amount for each month of the agreement.

RATIONALE: *This document avoids the need for mailing a monthly statement for the agreed-upon amount to the patient.*

PROCEDURE 20-9 Making a Bank Deposit

WORK // DOC

Procedure Goal: To prepare cash and checks for deposit and to deposit them properly into a bank account

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Bank deposit slip and items to be deposited, such as checks, cash, and money orders

Method:

1. Divide the bills, coins, checks, and money orders into separate piles.
2. Sort the bills by denomination, from largest to smallest. Then, stack them—portrait side up—in the same direction. Total the amount of the bills and write this amount on the deposit slip on the line marked "currency" or cash.

RATIONALE: *The bank will require bills to be sorted for ease of counting by the teller to verify deposit information.*
3. If you have enough coins to fill coin wrappers, put them in wrappers of the proper denomination. If not, count the coins and put them in the deposit bag. Total the amount of coins and write this amount on the deposit slip on the line marked "Coin."

RATIONALE: *If there are enough coins to fill denomination wrappers, the bank will require this to be done.*

4. Review all checks and money orders to be sure they are properly endorsed with a restrictive endorsement. List each check on the deposit slip, including the check number and amount.

RATIONALE: *Without a proper endorsement, the bank will not accept a check for deposit.*
5. List each money order on the deposit slip. Include the notation "money order" or "MO" and the name of the writer.
6. Calculate the total deposit (total of amounts for currency, coin, checks, and money orders). Write this amount on the deposit slip on the line marked "Total." If you do not use deposit slips that record a copy for the office, photocopy the deposit slip for your office records.

RATIONALE: *Deposit slips must be kept in case there is ever a discrepancy between the office and bank records. The deposit slip is proof of deposit.*
7. Record the total amount of the deposit in the office checkbook register.
8. If you plan to make the deposit in person, place the currency, coins, checks, and money orders in a deposit bag. If you cannot make the deposit in person, put the checks and money orders in a special bank-by-mail

envelope or put all deposit items in an envelope and send it via registered mail.

RATIONALE: *If a deposit absolutely must be mailed, registered mail provides insurance for the amount of the deposit and proof of receipt by the bank.*

9. Make the deposit in person or by mail.
10. Obtain a deposit receipt from the bank. File it with the copy of the deposit slip in the office for later use when reconciling the bank statement.

PROCEDURE 20-10 Reconciling the Bank Statement

WORK // DOC

Procedure Goal: To ensure that the bank record of deposits, payments, and withdrawals agrees with the practice record of deposits, payments, and withdrawals

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Previous month's bank statement, current month's bank statement, reconciliation worksheet (if not part of current bank statement), deposit receipts, red pencil, check stubs or checkbook register, returned checks or listing of checks returned

Method:

1. Check the closing balance on the previous month's statement against the opening balance on the current month's statement. The balances should match. If they do not, call the bank.
RATIONALE: *If the ending balance from last month does not match the beginning balance of this month, there may be a problem with the bank's system.*
2. Record the closing balance from the current statement on the reconciliation worksheet (Figure 20-17). This worksheet usually appears on the back of the bank statement.
RATIONALE: *This is the starting point for adjusting the bank balance as needed to accomplish reconciliation.*
3. Check each deposit receipt against the bank statement.
 - a. Place a red check mark in the upper-right corner of each receipt recorded on the statement.
 - b. Also place a check mark next to each deposit recorded in the checkbook to be sure none was skipped in this record.
4. Total the amount of deposits that do *not* appear on the statement. Add this amount to the closing balance from the bank on the reconciliation worksheet.
RATIONALE: *These deposits are in transit, but the amount must be added to the bank balance in order for reconciliation to occur.*
5. Compare each redeemed check with the bank statement, making sure that the amount on the check agrees with the amount on the statement.
 - a. Place a red check mark in the upper-right corner of each redeemed check recorded on the statement.
 - b. Also, place a check mark on the check stub or check register entry.
 - c. Any checks that were written but do not appear on the statement and were not returned as redeemed are considered "outstanding" checks. You can find these easily on the check stubs or checkbook register because they have no red check mark next to them.
6. List each outstanding check separately on the worksheet, including its check number and amount. Total the outstanding checks and subtract this total from the bank statement balance.
RATIONALE: *These checks will eventually be honored by the bank. In order to balance the checkbook and bank statement, these outstanding checks must be subtracted from the bank balance. (You cannot add the amount back to your checkbook because the money will not be returned to the account.)*
7. Record the ending balance found in the office checkbook in the appropriate area of the reconciliation worksheet.
RATIONALE: *This is the starting point for adjusting the checkbook balance as needed to accomplish reconciliation.*
8. If the statement shows that the checking account earned interest, add this amount to the checkbook balance.
RATIONALE: *You did not know the interest amount prior to today, so now it must be added to the bank balance both in the checkbook and on the reconciliation worksheet.*
9. If the statement lists such items as service charge, check printing charge, or automatic payment, subtract them from the checkbook balance and add these charges to the checkbook register itself.
RATIONALE: *In order to balance with the bank statement, you must now enter the information you did not know until now, both in the checkbook register and on the reconciliation worksheet.*
10. Compare the new checkbook balance with the new bank statement balance. They should match. If they do not, repeat the process, rechecking all calculations. Double-check the addition and subtraction in the checkbook register. Review the checkbook register to make sure you did not omit any items. Ensure that you carried the correct balance forward from one register page to the next. Double-check that you made the correct additions or subtractions for all interest earned and charges incurred.
11. If you have double-checked your work and the balances still do not agree, ask a coworker to check your figures. If the coworker also finds no error or omission, call the bank to determine if a bank error has been made. Contact the bank promptly because the bank may have a time limit for corrections and may consider the bank statement correct if you do not point out an error within a specified time. Check with your individual bank for its policy.
RATIONALE: *Always ask a "fresh set of eyes" to look at the reconciliation prior to calling the bank. If anyone looks at figures for too long, it is not unusual to see "what you want to see," instead of what is really there.*

PROCEDURE 20-11 Setting Up the Disbursements Journal

WORK // DOC

Procedure Goal: To set up the office disbursements journal

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Disbursements journal (either paper or electronic), pen (if journal is in a paper format), listing of the headings required for the disbursements journal

Method:

1. Write in or key column headings for the basic information required for each check: date, payee's name, check number, and check amount.

RATIONALE: This information is needed for accounting purposes.

2. Enter column headings for each type of business expense, such as utilities, payroll, and taxes.

3. Write in column headings (if space is available) for deposits and the account balance.

4. Record the data from completed checks under the appropriate column headings.

RATIONALE: The amount spent on each type of business expense is entered and tracked for income and expense reports. The practice manager will know exactly where money is being made or lost.

5. Be sure to subtract payments from the balance and add deposits to it.

RATIONALE: This step allows for a running tally of income and expenses, including the current balance.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
20.1 Summarize the importance of and how to establish good bookkeeping and banking practices.	Procedures to be established to help maintain consistency in financial practices include being organized and consistent. Write clearly and use markers to keep track of your current location. Check your work frequently and correct any errors using the approved method of drawing one line through the error and correcting the information directly above that location. All entries must be kept readable at all times. Finally, keep all figure columns straight so that decimal points line up. Following through on these procedures can help ensure that your work will be concise and accurate.
20.2 Compare single-entry, double-entry, and write-it-once bookkeeping systems and explain accounts receivable and payable.	The single-entry accounting system is easy to use because each entry is written once on the patient ledger, on the daily log, and in the checkbook but contains no checks and balances for accuracy. The double-entry system is based on $\text{Assets} = \text{Capital} + \text{Liabilities}$. It has checks and balances but can be cumbersome and complicated. The write-it-once system is used in manual offices because it allows all transactions to be recorded in one procedure, using carbonless forms on all necessary documents. Many office management software packages are based on the write-it-once concept. <i>Accounts receivable</i> refers to the money that is owed to the practice (able to be received). <i>Accounts payable</i> refers to the money that the practice owes other vendors (able to be paid).
20.3 Describe the common payment methods accepted in medical practices today.	Common payment methods accepted by medical practices include cash, check, money orders, and debit and credit cards.
20.4 Identify the different types of documents used as statements to bill patients and how these documents are used in cycle billing.	Common statement documents include the use of superbills, typed or computer-produced itemized statements, and copies of ledger cards. In cycle billing the accounts are split in groups and statement mailing dates are staggered.

LEARNING OUTCOMES	KEY POINTS
20.5 Compare open-book, written-contract, and single-entry accounts and the purpose of creating an accounts receivable aging.	An open-book account is the account type most commonly found in a medical practice, consisting of periodic charges and payments added as needed when patients are seen in the practice. A written-contract account is used when the physician and patient sign a contract for a specific service or procedure. A single-entry account is used for patients when it is expected they will be seen only once, such as for a relative visiting the area on vacation. An age analysis is the process of classifying and reviewing past-due accounts by age from the first date of billing. It helps you keep on top of past-due accounts and determine which ones need follow-up.
20.6 Explain the purposes of the following credit and collections acts: ECOA, FCRA, FDCPA, and TLA.	The Equal Credit Opportunity Act (ECOA) prohibits discrimination based on sex, marital status, race, national origin, religion, or age. Applicants also cannot be discriminated against for receiving public assistance income or exercising their rights under the Consumer Credit Protection Act. The Fair Credit Reporting Act (FCRA) requires credit bureaus to supply correct and complete information to businesses to use in evaluating a person's application for credit, insurance, or a job. The Fair Debt Collections Practices Act (FDCPA) requires debt collectors to treat debtors fairly and prohibits certain collection tactics, including harassment, false statements, threats, and unfair practices. The Truth in Lending Act (TLA) requires creditors to provide applicants with accurate and complete credit costs and terms.
20.7 Relate the required components of a Truth in Lending Statement to credit practices in the medical office.	The Truth in Lending Statement must include the following elements: the amount of total debt, the amount of the down payment, the amount of each payment and the date due, the due date for the final payment, the interest rate (if any) expressed as an annual percentage rate, and the total finance charges (if any).
20.8 Summarize two common types of problem collection accounts in the medical office.	The two most common types of collection problems in the medical office are hardship cases, who simply cannot afford to pay their debt, and accounts known as skips, where the debtor moved and left no valid forwarding information so it is not possible to bill the patient.
20.9 Identify negotiable instruments and the items that must be present for a check to be negotiable.	A negotiable instrument is one that is legally transferable from one person to another. To be negotiable, a check must be written and signed by the payer or maker, include the amount of money to be paid, be made payable to the payee or bearer, be made payable on demand or on a specific date, and include the name of the bank that is directed to make payment.
20.10 Describe the different types of check endorsements and the steps in creating a bank deposit.	The types of check endorsements are blank, restrictive, special, and qualified. To make a bank deposit, follow the steps outlined in Procedure 20-9.
20.11 Carry out the process of reconciling the office bank statement.	Follow Procedure 20-10 to successfully reconcile a mock bank statement with a mock office checkbook.

LEARNING OUTCOMES

20.12 List several advantages to electronic banking.

20.13 Implement setting up, classifying, and recording disbursements in a disbursements journal.

KEY POINTS

The computer software calculates each new balance for you. It can reconcile the monthly bank statement automatically and, instead of locking up bank forms and the office checkbook, a computer password and security system keep the information safe and confidential.

Following Procedure 20-11, set up a mock disbursements journal consisting of several columns of expenses. Once set up, given a list of several “bills” to be paid, document the check information and record the disbursement amount in the correct column(s) of the journal.

CASE STUDY CRITICAL THINKING

© John Lund/Sam Diephuis/Blend Images LLC RF

Recall Nancy Evans from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. How much of the \$360 bill for the neurology consult services will be Nancy’s responsibility? (Refer to the *Insurance and Billing* chapter if necessary.)
2. What is the best way to bill Nancy for this balance?
3. Why is this way the preferred method?

EXAM PREPARATION QUESTIONS

1. (LO 20.1) Which of the following is *not* a procedure to be followed when setting up bookkeeping or banking systems?
 - a. Be organized in your work area
 - b. Be consistent in your procedure
 - c. Use markers, jotting a red “x” as you work to avoid losing your place
 - d. Write clearly in pen, using the same color of ink
 - e. Check your work carefully
2. (LO 20.3) The form that contains a single patient’s financial information and record of transactions is called the patient
 - a. Day sheet
 - b. Check
 - c. Pegboard
 - d. Daily log
 - e. Ledger card
3. (LO 20.3) Which of the following is the preferred way to ask a patient for payment?
 - a. “I need \$50 for today’s visit.”
 - b. “The total for today’s visit is 50 bucks. How do you want to pay for that?”
 - c. “That will be \$50. What is your check number?”
 - d. “Your anticipated charge for today is \$50. We require payment up front.”
 - e. “Your charge for today’s visit is \$50. We take cash, check, and credit and debit cards.”
4. (LO 20.4) Which of the following would *not* be acceptable for use as a patient statement?
 - a. A completed superbill
 - b. A handwritten statement
 - c. A computer-generated statement
 - d. A “clean” copy of the office ledger card
 - e. A typed statement

5. (LO 20.5) What is the most important reason for running an age analysis of the patient accounts?
 - a. It allows you to see “deadbeats” at a glance
 - b. It allows you to track the “high dollar” accounts
 - c. It tracks delinquent insurance payments
 - d. It allows you to track past-due accounts so that the patients can be contacted
 - e. It lets the physician know how much money is owed to the practice
6. (LO 20.6) Which of the following laws govern(s) collection policies in medical practices?
 - a. ECOA
 - b. FCRA
 - c. FDCPA
 - d. TLA
 - e. ECOA, FCRA, and TLA
7. (LO 20.7) Under what conditions is a Truth in Lending Statement required?
 - a. When the physician informally agrees that the patient can pay a bill in installments
 - b. If a bilateral agreement of fewer than four installments is reached
 - c. When the patient pays at the time of service
 - d. When a finance charge is to be assessed by the practice
 - e. All of these require a Truth in Lending Statement
8. (LO 20.9) Business (or personal) checks with stubs attached are known as
 - a. Counter checks
 - b. Voucher checks
 - c. Limited checks
 - d. Traveler’s checks
 - e. Cashier’s checks
9. (LO 20.9) The best endorsement to use on a daily basis when preparing checks for the office deposit is the _____ endorsement.
 - a. Blank
 - b. Special
 - c. Restrictive
 - d. Third-party
 - e. Qualified
10. (LO 20.13) A payment made by the office for goods or services purchased is known as
 - a. Disbursement
 - b. Accounts payable
 - c. Accounts receivable
 - d. Liability
 - e. Capital

SOFT SKILLS SUCCESS

Recall Nancy Evans from the case study at the beginning of the chapter.

1. Even though her short-term memory is starting to be affected by her disease, Mrs. Evans is still interested and involved in her medical care and financial matters. In fact, she asks about her balance today. How can you help make sure that she does not forget important information?
2. Because Mrs. Evans asked about her balance, you give her a copy of today’s encounter form. She states (correctly) that this is not the “usual bill.” What will you say to her?

PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	082-09-981	Ordered: CXR-AP and Lateral Views

John Miller, a 65-year-old male, arrives at the clinic complaining of his shoes not fitting and feeling like he cannot take a deep breath. During the patient interview, he also states he is having intermittent pain in his chest. He has not taken his blood pressure medication for 2 weeks because he ran out of the medication and there were no

© McGraw-Hill Education

refills left on his prescription. He is hoping to get this medication renewed. The licensed practitioner wants to evaluate his congestive heart failure and orders a chest X-ray. You know from your study of anatomy that the X-ray will provide an image of the structures in the thoracic cavity.

Keep John in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 21, you will be able to:

- 21.1** Explain the importance of understanding both anatomy and physiology when studying the body.
- 21.2** Illustrate body organization from simple to more complex levels.
- 21.3** Describe the locations and characteristics of the four main tissue types.
- 21.4** Describe the body organ systems, their general functions, and the major organs contained in each.
- 21.5** Use medical and anatomical terminology correctly.
- 21.6** Explain anatomical position and its relationship to other anatomical positions.
- 21.7** Identify the body cavities and the organs contained in each.
- 21.8** Relate a basic understanding of chemistry to its importance in studying the body.
- 21.9** Name the parts of a cell and their functions.
- 21.10** Summarize how substances move across a cell membrane.
- 21.11** Distinguish the stages of cell division.
- 21.12** Explain the uses of these genetic techniques: the polymerase chain reaction and DNA fingerprinting.
- 21.13** Describe the different patterns of inheritance and common genetic disorders.
- 21.14** Describe the causes, signs and symptoms, and treatments of various genetic diseases and disorders.

MEDICAL ASSISTING COMPETENCIES

CAAHEP

- I.C.1** Describe structural organization of the human body
- I.C.2** Identify body systems
- I.C.3** Describe:
 - (a) body planes
 - (b) directional terms
 - (c) quadrants
 - (d) body cavities
- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.7** Describe the normal function of each body system
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

ABHES

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms and etiologies as they apply to each system

3. Medical Terminology

- a. Define and use entire basic structure of medical words and be able to accurately identify in the correct context; i.e. root, prefix, suffix, combinations, spelling, and definitions
- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply the various medical terminology for each specialty

► Introduction

The human body is complex in its structure and function. Think of your own body for a moment. If you were to choose just one body part—say, your eyes—consider everything about how they look, how they function, how they are connected to the rest of your face, and how your skull supports them. Consider what happens to your eyes when you smile, cry, or glimpse bright sunlight or when a misguided insect or piece of dirt makes its way into them and you have to rub one eye with your finger and you end up scratching it accidentally, causing temporarily blurred vision.

Of course, the eyes are just one example. You have your entire body to deal with. This chapter provides an overview of the human body. It introduces you to the way the body is organized from the chemical level all the way up to the organ system level. You will learn important terminology used to describe body positions and parts. You will also explore how diseases develop at the genetic and organism levels.

► The Study of the Body

LO 21.1

Anatomy is the scientific term for the study of body structure. For example, the heart may be described as a hollow, cone-shaped organ that is an average of 14 centimeters long and 9 centimeters wide. Understanding anatomy allows us to understand the normal positions of body structures and how to describe these positions precisely and correctly. **Physiology** is the term for the study of the function of the body's organs. For example, the physiology of the heart can be described by saying that the heart pumps blood into blood vessels to transport nutrients throughout the body. Anatomy and physiology are commonly studied together because they are intimately related. For example, the anatomy of the heart (a hollow, muscular organ) allows it to do its function (pump blood into tubular blood vessels). If the heart were not hollow, it could not allow blood to flow into it. If the heart were not muscular, it could not pump blood.

Knowledge of anatomy and physiology will help you grasp the meaning of diagnosis and procedure codes and help you

understand the clinical procedures you will perform and assist with as a medical assistant. Understanding anatomy and physiology can also make it easier to see how and why certain diseases develop. Diseases develop in the body when homeostasis—the relative consistency of the body’s internal environment—is not maintained. Body conditions that must remain within a stable range include body temperature, blood pressure, and the concentration of various chemicals within the blood. Individual cells must also maintain homeostasis. For example, if chemicals within a cell change the deoxyribonucleic acid (DNA), or genetic makeup of the cell, that cell can become cancerous.

simplest units of all **matter**, anything that takes up space and has weight, and many are essential to life. The four most common atoms in the human body are carbon, hydrogen, oxygen, and nitrogen. **Molecules** are made up of atoms that bond together. Proteins and carbohydrates are examples of molecules that consist of hundreds of atoms.

Molecules join together to form **organelles**, which can be thought of as cell parts. Organelles combine to form cells such as leukocytes (white blood cells), erythrocytes (red blood cells), neurons (nerve cells), and adipocytes (fat cells). **Cells** are considered to be the smallest living units in the body. When similar types of cells organize together, they form **tissues**. Two or more tissue types combine to form **organs**, and organs arrange to form **organ systems**. Finally, organ systems combine to form an **organism**. Figure 21-1 illustrates the organization of the body’s organ systems.

► Structural Organization of the Body

LO 21.2

The body’s structure can be divided into different levels of organization. The chemical level is the simplest level—the billions of atoms and molecules in the body. Atoms are the

► Major Tissue Types

LO 21.3

Tissues are groups of cells that have similar structures and functions. The four major tissue types in the body are epithelial, connective, muscle, and nervous tissue. These are explained more fully in the following paragraphs.

FIGURE 21-1 The human body is organized in levels, beginning with the chemical level and progressing to the cellular, tissue, organ, organ system, and organism (whole body) levels.

Epithelial Tissue

When you think of epithelial tissue, think of a covering, lining, or gland. Epithelial tissue covers the body and most organs in the body. It lines the body's tubes, such as blood vessels and the esophagus, and the body's hollow organs, such as the stomach and heart. This type of tissue also lines body cavities, such as the thoracic cavity and the abdominopelvic cavity.

Glandular tissue is also classified as a type of epithelial tissue. It is composed of cells that make and secrete (give off) substances. If a gland secretes its product into a duct, as does a sweat or oil (sebaceous) gland, it is called an *exocrine gland*. If a gland secretes its product directly into surrounding tissue fluids or blood, it does not have ducts and is called an *endocrine gland*. The pancreas and thyroid are considered endocrine glands because they release their hormones directly into the bloodstream.

Epithelial tissues are avascular, which means they lack blood vessels. However, these tissues have a nerve supply and are very mitotic, meaning they divide constantly. In addition, the cells within epithelial tissues are packed together tightly. Epithelial tissues have many different functions, depending on their location in the body. For example, those covering the body protect against invading pathogens and toxins. Those that line the digestive tract secrete a variety of enzymes needed for digestion. They often possess microvilli—tiny, fingerlike projections that allow the body to absorb nutrients. Epithelial tissues lining the respiratory tract have goblet cells and cilia. The goblet cells produce mucus, which traps small particles that enter the respiratory tract. The cilia constantly push the mucus and trapped particles away from the lungs (see Figure 21-2). Epithelial cells within the kidneys act as filters to help remove waste products from the blood.

Connective Tissue

Connective tissue is the most abundant tissue in the body. The cells of connective tissue are not packed together tightly. Instead, a matrix separates the cells. Think of the matrix simply as the matter between the cells of connective tissue. The matrix may contain fibers, water, proteins, inorganic salts, and other substances. The components of the matrix vary, depending on the type of connective tissue. Connective tissue generally has a rich blood supply, except for cartilage and some dense connective tissues that contain a very poor blood supply.

Many different cell types are located in connective tissue; the most common are fibroblasts, mast cells, and macrophages. Fibroblasts are responsible for secreting collagen and making fibers. They are essential for the normal development and repair of connective tissue. Mast cells secrete substances such as heparin and histamine that promote inflammation when tissue is damaged. Macrophages are cells that destroy unwanted material, such as bacteria or toxins.

The following sections discuss the various types of connective tissue in more detail.

Blood This tissue is composed of red blood cells, white blood cells, platelets, and plasma. Plasma is the matrix of blood. Unlike other connective tissues, this matrix does not contain fibers. Blood transports substances throughout the body. Blood and its cell functions will be discussed in depth in a later chapter.

FIGURE 21-2 Epithelial tissue lining the respiratory tract.

© McGraw-Hill Education/Al Telser, photographer

Osseous (Bone) Tissue The matrix of osseous tissue contains mineral salts that make it a very hard tissue. Contrary to popular belief, bone is a living tissue—it is metabolically active.

Cartilage The matrix of cartilage is rigid, although it is not as hard as osseous tissue. Cartilage gives shape to structures such as the ears and nose. It also protects the ends of long bones and forms the discs between the vertebrae of the neck and spine.

Dense Connective Tissue The matrix of dense connective tissue is packed with tough fibers that make it a soft but very strong tissue. Ligaments, tendons, and joint capsules have large amounts of this tissue type. Ligaments connect bones to bones, tendons connect muscles to bones, and joint capsules surround moveable joints in the body. Dense connective tissue also makes up a large part of the skin's dermis. When skin is damaged, this tissue “fills in” the damaged space and forms a scar.

Adipose (Fat) Tissue Within adipose tissue, unique cells—adipocytes—store fats. This tissue type stores energy for body cells, cushions body parts and organs, and insulates the body against excessive heat or cold (see Figure 21-3).

Muscle Tissue

Muscle is a specialized type of tissue that contracts and relaxes. The three types of muscle tissue are skeletal, visceral (smooth), and cardiac.

FIGURE 21-3 Adipose tissue.
© McGraw-Hill Education/AI Telser, photographer

Skeletal Muscle Tissue As its name suggests, skeletal muscle tissue is attached to the skeleton. This type of tissue is voluntary because we can consciously control its movement. For example, we can consciously decide to contract the skeletal muscles attached to our arm bones and make them move. It is also referred to as striated because the cells of this muscle tissue type have striations, or stripes, in their cytoplasm (see Figure 21-4).

Visceral Muscle Tissue This smooth muscle tissue is located in the walls of hollow organs (except the heart), the walls of blood vessels, and the dermis of skin. It is involuntary—we cannot consciously control its movement. For example, you do not consciously decide when the visceral muscle of your stomach contracts. This tissue is also called *smooth muscle* because its cells do not have striations in their cytoplasm.

FIGURE 21-4 Skeletal muscle tissue.
© Science Photo Library RF/Getty Images

FIGURE 21-5 Nervous tissue.
© Science Photo Library RF/Getty Images

Cardiac Muscle Tissue This specialized muscle tissue is located in the wall of the heart. Like skeletal muscle tissue, cardiac muscle is striated. Like smooth muscle tissue, it is not under voluntary control; it is involuntary.

Nervous Tissue

Nervous tissue is located in the brain, spinal cord, and peripheral nerves. This tissue specializes in sending impulses, or electrical messages, to the neurons, muscles, and glands in the body (see Figure 21-5). Nervous tissue contains two types of cells: neurons and neuroglial cells. Neurons are the largest cells, and they transmit impulses. Although neuroglial cells are smaller, they are more abundant and act as support cells for the neurons. They do not transmit impulses.

Body Organs and Systems

LO 21.4

Organs are structures formed by the organization of two or more different tissue types that work together to carry out specific functions. For example, the heart is made up of cardiac muscle tissue, connective tissue, and epithelial tissue. These tissues work together to carry out the heart's function—to effectively pump blood into blood vessels. Organ systems are formed when organs join together to carry out vital functions. For example, the heart and blood vessels unite to form the cardiovascular system. The organs of the cardiovascular system circulate blood throughout the body to ensure that all body cells receive enough nutrients. See Figure 21-6 for a summary of the human body's organ systems, their general functions, and the organs within each.

Integumentary System

Serves as a sense organ for the body, provides protection, regulates temperature, prevents water loss, and produces vitamin D precursors. Consists of skin, hair, nails, and sweat glands.

Skeletal System

Provides protection and support, allows body movements, produces blood cells, and stores minerals and fat. Consists of bones, associated cartilages, ligaments, and joints.

Muscular System

Produces body movements, maintains posture, and produces body heat. Consists of muscles attached to the skeleton by tendons.

Lymphatic System

Removes foreign substances from the blood and lymph, combats disease, maintains tissue fluid balance, and absorbs fats from the digestive tract. Consists of the lymphatic vessels, lymph nodes, and other lymphatic organs.

Respiratory System

Exchanges oxygen and carbon dioxide between the blood and air and regulates blood pH. Consists of the lungs and respiratory passages.

Digestive System

Performs the mechanical and chemical processes of digestion, absorption of nutrients, and elimination of wastes. Consists of the mouth, esophagus, stomach, intestines, and accessory organs.

FIGURE 21-6 Organ systems of the body.

(continued)

Nervous System

A major regulatory system that detects sensations and controls movements, physiologic processes, and intellectual functions. Consists of the brain, spinal cord, nerves, and sensory receptors.

Endocrine System

A major regulatory system that influences metabolism, growth, reproduction, and many other functions. Consists of glands, such as the pituitary, that secrete hormones.

Cardiovascular System

Transports nutrients, waste products, gases, and hormones throughout the body; plays a role in the immune response and the regulation of body temperature. Consists of the heart, blood vessels, and blood.

Urinary System

Removes waste products from the blood and regulates blood pH, ion balance, and water balance. Consists of the kidneys, urinary bladder, and ducts that carry urine.

Female Reproductive System

Produces oocytes and is the site of fertilization and fetal development; produces milk for the newborn; produces hormones that influence sexual function and behaviors. Consists of the ovaries, vagina, uterus, mammary glands, and associated structures.

Male Reproductive System

Produces and transfers sperm cells to the female and produces hormones that influence sexual functions and behaviors. Consists of the testes, accessory structures, ducts, and penis.

FIGURE 21-6 Organ systems of the body.

► Understanding Medical Terminology

LO 21.5

Unlike the English language, in which word meanings often seem to have no rhyme or reason—like the overly used “whatever” and various difficult-to-translate modern slang—medical terminology often can be broken down into word parts that make the meaning concrete and easy to understand. All medical terms must have a **word root** that contains the base meaning for the term and a **suffix** at the end of the term that alters the word root’s meaning. In the term *appendectomy*, for example, the word root *append* refers to the appendix and is combined with the suffix *-ectomy*, which means “surgical removal.” So *appendectomy* means “surgical removal of the appendix.” The word parts’ meanings stay consistent, making it easier to learn new terms containing already understood word parts. Using your new knowledge, if you are told that the word root *hyster* means “uterus,” you can easily see that *hysterectomy* means “surgical removal of the uterus.”

In addition to word roots and suffixes, some terms also contain a **prefix**, which comes at the beginning of the term and, like the suffix, alters the term’s meaning. Let’s take the terms *premenstrual* and *postmenstrual*. In defining terms, the general rule is to start with the suffix, then add the prefix (if present), and finally the word root(s)—for example,

- The suffix *-al* means “pertaining to.”
- The prefix *pre-* means “before.”
- The prefix *post-* means “after.”

The word root *menstru* refers to the menstrual period. Putting them together, *premenstrual* means “pertaining to *before* the menstrual period” and *postmenstrual* is “pertaining to *after* the menstrual period.”

For terms in which the suffix begins with a consonant, a combining vowel—often an “o”—is used between the word root and the suffix to ease pronunciation. An example of this is the term *tracheotomy*. The word root *trache* (“windpipe”) is joined to the suffix *-tomy* (“to cut into”). The letter “o” is inserted between the two to make pronunciation easier. Unlike prefixes and suffixes, combining vowels do not change the meaning of the term. Appendix I contains commonly used word roots, suffixes, and prefixes. Table 21-1 summarizes information on understanding medical terminology.

► Anatomical Terminology

LO 21.6

Anatomical terms describe the locations of body parts and various body regions. To correctly use these terms, it is assumed that the body is in the anatomical position. For example, picture yourself in the **anatomical position**: Your body is standing upright and facing forward, and your arms are at your sides with the palms of your hands facing forward. Even if patients are lying down, for consistency and correct communication when you use anatomical terms, always refer to patients as if they were in the anatomical position. Anatomical position is pictured later in this chapter.

TABLE 21-1 Understanding Medical Terminology

Word Part	Description	Term Using Word Part	Term Meaning
Word root	Base meaning of the term	Colostomy	Colo = colon; -stomy = to cut (or create) a new opening colostomy: to cut a new opening for the colon
Suffix	Ending of term; alters meaning of the word root	Cardiology	Cardi = heart; -logy = knowledge of cardiology: knowledge (specialty) of the heart (with the combining vowel “o” between the two to ease pronunciation)
Prefix	Beginning of the term; alters the meaning of the word root	Tachycardia	Tachy- = rapid; cardi = heart; -ia = condition of tachycardia: condition of rapid heart (beat)
Combining vowel	Placed between word root and suffix to ease pronunciation	Cardiologist	Cardi = heart; o = combining vowel to ease pronunciation; -logist = specialist in knowledge of cardiology: specialist in the knowledge of the heart

TABLE 21-2 Directional Anatomical Terms

Term	Definition	Example
Superior (cranial)	Above or close to the head	The thoracic cavity is superior to the abdominal cavity.
Inferior (caudal)	Below or close to the feet	The neck is inferior to the head.
Anterior (ventral)	Toward the front of the body	The nose is anterior to the ears.
Posterior (dorsal)	Toward the back of the body	The brain is posterior to the eyes.
Medial	Close to the midline of the body	The nose is medial to the ears.
Lateral	Farther away from the midline of the body	The ears are lateral to the nose.
Proximal	Close to a point of attachment or to the trunk of the body	The knee is proximal to the toes.
Distal	Farther away from a point of attachment or from the trunk of the body	The fingers are distal to the elbow.
Superficial	Close to the surface of the body	Skin is superficial to muscles.
Deep	More internal	Bones are deep to skin.

Directional Anatomical Terms

The directional anatomical terms that identify the position of body structures compared to other body structures are *superior (cranial)*, *inferior (caudal)*, *anterior (ventral)*, *posterior (dorsal)*, *medial*, *lateral*, *proximal*, *distal*, *superficial*, and *deep*. For example, the eyes are medial to the ears but lateral to the nose. See Table 21-2 and Figure 21-7 for an explanation and illustration of these important directional terms.

Anatomical Terms That Describe Body Sections

Sometimes in order to study internal body parts, it helps to imagine the body as being divided into sections. Medical professionals often use the following terms to describe how the body is divided into sections:

- A *sagittal plane* divides the body into left and right portions.
- A *midsagittal plane* runs lengthwise down the midline of the body and divides it into equal left and right halves.

- A *transverse plane* divides the body into superior (upper) and inferior (lower) portions.
- A *frontal*, or *coronal*, plane divides the body into anterior (frontal) and posterior (rear) portions.

Figure 21-8 illustrates these planes.

Anatomical Terms That Describe Body Parts

Many other anatomical terms describe different regions or parts of the body. For example, the term *brachium* refers to the arm, and the term *femoral* refers to the thigh. Figure 21-9 illustrates anatomical position in (a) and many of the common anatomical terms that describe body parts.

► Body Cavities and Abdominal Regions

LO 21.7

Body cavities house and protect the internal organs. The largest body cavities are the dorsal cavity and the ventral cavity. The dorsal cavity is divided into the cranial cavity (which

FIGURE 21-7 Directional terms provide mapping instructions for locating organs and body parts.

FIGURE 21-8 Spatial terms are based on imaginary cuts, or planes, through the body.

houses the brain) and the spinal cavity (which contains the spinal cord). The ventral cavity is divided into the thoracic cavity and the abdominopelvic cavity. The muscle called the *diaphragm* separates the thoracic and abdominopelvic cavities. The thoracic cavity contains the following:

- Lungs
- Heart
- Esophagus
- Trachea

The abdominopelvic cavity is divided into a superior abdominal cavity and an inferior pelvic cavity. It contains the following:

- Stomach
- Small and large intestines
- Gallbladder

- Liver
- Spleen
- Kidneys
- Pancreas

The bladder and internal reproductive organs are located in the pelvic cavity, which is depicted in Figure 21-10. The abdominal area is further divided into nine regions or four quadrants, which are illustrated in Figure 21-11.

► Chemistry of Life

LO 21.8

Now that you have studied how the body is organized structurally, you need to learn about its chemical structure. **Chemistry** is the study of what matter is made of and how it changes. It is important to have a basic understanding of chemistry when studying anatomy and physiology because

FIGURE 21-9 Numerous anatomical terms describe regions of the body: (a) anterior view and (b) posterior view.

body structures and functions result from chemical processes that occur within body cells and fluids.

As you learned earlier in the chapter, the chemical level is the lowest level of organization. The building blocks of every living organism are the same chemical elements that make up all matter, liquids, solids, and gases. When two or more atoms

are chemically combined, a molecule is formed. A compound is formed when two or more atoms of different elements are combined. For example, a molecule of oxygen (O_2) is not a compound, because it is made up of only one element. In contrast, a water molecule is a compound, because it is made up of atoms of two different elements—two hydrogen atoms and one oxygen atom. Water is critical to both chemical and physical processes in human physiology, and it accounts for approximately two-thirds of a person's body weight.

Metabolism is the overall chemical functioning of the body. It is a series of life-sustaining processes, including the breakdown of food and its transformation into energy. The two processes of metabolism are anabolism and catabolism. In anabolism, small molecules combine to form larger ones

FIGURE 21-10 The two main body cavities are dorsal and ventral.

(for example, when amino acids combine to form proteins). In catabolism, larger molecules are broken down into smaller ones (for example, when stored glycogen is converted to glucose molecules for energy).

Electrolytes

When put into water, some substances release **ions**, which are either positively or negatively charged particles. These substances are called **electrolytes**. For example, when you put sodium chloride (NaCl) in water, it releases two electrolytes: the sodium ion (Na) and the chloride ion (Cl). Electrolytes are critical because the movements of ions into and out of body structures regulate or trigger many physiologic states and activities in the body. For example, electrolytes are essential to fluid balance, muscle contraction, and nerve impulse conduction. Exercising makes you sweat, causing fluid and electrolyte loss. Drinking a sports drink after exercising helps you maintain fluid balance because sports drinks contain water and electrolytes such as sodium and potassium.

Acids and Bases Acids are substances that release hydrogen ions (H^+) in water. Many acids, such as lemon juice and vinegar, have a sour taste. Bases are substances that release hydroxyl ions (OH^-) in water. A basic substance may also be referred to as an alkali. Many basic substances are slippery and bitter to the taste. Laundry detergents, bleach, dish soaps, and many other household cleaning agents are examples of basic substances.

Testing Acids and Bases In the clinical setting, litmus paper, liquid pH indicator test kits, or a pH meter is often used to determine if a substance is acidic or basic. An acidic

FIGURE 21-11 (a) The abdominal area divided into nine regions and (b) the abdominal area divided into four quadrants.

FIGURE 21-12 pH scale. As the concentration of hydrogen ions (H^+) increases, a solution becomes more acidic, and the pH decreases. As the concentration of hydroxyl ions (OH^-) increases, a solution becomes more basic and the pH increases.

substance will turn blue litmus paper red, and a basic substance will turn red litmus paper blue. The pH scale runs from 0 to 14. If a solution has a pH of 7, the solution is neutral, which means it is neither acidic nor basic. If a solution has a pH less than 7, the solution is acidic. If a solution has a pH greater than 7, it is basic, or alkaline. The more acidic a solution is, the higher the concentration of hydrogen ions it contains. The pH values of some common substances are shown in Figure 21-12.

Biochemistry

Biochemistry is the study of matter and chemical reactions in the body. Matter can be divided into two large categories: organic and inorganic matter. Organic matter contains carbon and hydrogen, and its molecules tend to be large. Inorganic matter generally does not contain carbon and hydrogen; these molecules tend to be small. Examples of inorganic substances are water, oxygen, carbon dioxide, and salts such as sodium chloride. Water is the most abundant inorganic compound in the body. The four major classes of organic matter in the body are carbohydrates, lipids, proteins, and nucleic acids. These are outlined in the following sections.

Carbohydrates Body cells depend on carbohydrate molecules to make energy. The carbohydrate most commonly used by the body cells is glucose. A type of carbohydrate commonly found in potatoes, pastas, and breads is starch, which is broken down into glucose when needed.

Lipids Lipids are fats. Three types of lipids are found in the body: triglycerides, phospholipids, and steroids. Triglycerides store energy for cells, and phospholipids primarily make cell membranes. Butter and oils are composed of triglycerides, and the body stores these molecules in adipose tissue (fat). Steroids are very large lipid molecules that make cell

membranes and some hormones. Cholesterol is an example of an essential steroid for body cells.

Proteins Proteins have many functions in the body. Many proteins act as structural materials for the building of solid body parts. Other proteins act as hormones, enzymes, receptors, and antibodies.

Nucleic Acids DNA (deoxyribonucleic acid) and RNA (ribonucleic acid) are two examples of nucleic acids. DNA contains the genetic information of cells, and RNA makes proteins. Nucleic acids are made up of nucleotides, which are discussed later in this chapter.

Cell Characteristics

LO 21.9

Chemicals react to form the complex substances that make up cells, the basic unit of life. The human body is composed of millions of cells. There are many kinds of cells, and each type has a specific function. Most cells have three main parts: cell membrane, cytoplasm (liquid matrix containing each cell's organelles), and nucleus. Figure 21-13 shows the structure of a composite cell.

Cell Membrane

The cell membrane is the outer limit of a cell. It is very thin and selectively permeable, which means that it allows some substances to pass through it while preventing other substances from passing through. Think of a fence and gate at an amusement park; people who have a ticket can enter through the gate, but those who do not have a ticket are kept behind the fence. The cell membrane is composed of two layers of phospholipids, different types of proteins, cholesterol, and a few carbohydrates.

Cytoplasm and Its Organelles

The cytoplasm is the “inside” of the cell. Mostly made up of water, proteins, ions, and nutrients, the cytoplasm houses organelles that perform many cell functions, and therefore body system functions. These organelles include cilia, the flagellum, ribosomes, the endoplasmic reticulum, mitochondria, the Golgi apparatus, lysosomes, and centrioles.

FIGURE 21-13 A composite cell drawing showing the structures that are common to many cell types. Not all types of cells have all of these structures.

- Many cells contain hair-like projections on the outside of the cell membrane called *cilia*. Cilia assist with propelling matter throughout the body tracts, including the respiratory system. Cells with cilia are often found in the mucous membranes.
- A flagellum is a tail-like structure found on the human sperm cell and provides its “swimming” type of locomotion.
- Ribosomes, in conjunction with RNA molecules, are responsible for protein synthesis. Amino acids are connected together to form proteins through a specialized process involving different types of RNA molecules. The ribosome supports the protein chain as it is formed.
- The endoplasmic reticulum comes in two forms—smooth and rough. The rough endoplasmic reticulum is named for the presence of ribosomes on its surface, which give it a bumpy or rough appearance. Both types of endoplasmic reticulum form networks, or passageways, for transporting substances throughout the cytoplasm.
- Mitochondria—the centers for cell respiration—provide energy for the cell. There may be only one mitochondrion in a cell or many, depending on how much energy each cell type requires.
- The cell’s Golgi apparatus is known to process and sort proteins from the ribosome and to synthesize or produce

carbohydrates. It is also thought to prepare and store secretions for discharge from the cell.

- The organelles known as lysosomes perform the cell's digestive function.
- The centrioles—two cylindrical organelles near the nucleus—are essential to cell division, as they equally distribute chromosomes to the resultant “daughter” cells.

Nucleus

The nucleus of a cell is typically round and located near the center of a cell. It is enclosed by a nuclear membrane that contains nuclear pores, which allow larger substances to move into and out of the nucleus. It contains **chromosomes**, which are thread-like structures made up of DNA.

► Movement Through Cell Membranes

LO 21.10

The selectively permeable cell membrane controls what moves into and out of a cell. Recall that selective permeability means there is some selection, or choice, in what substances cross the membrane. Some substances, such as oxygen and water, move across the cell membrane without the use of energy. These movements are called *passive mechanisms*. Sometimes the cell has to use energy to move a substance across its membrane in movements known as *active mechanisms*. Large molecules, such as glucose and proteins, move across the cell membrane by active transport.

Diffusion

Diffusion is the movement of a substance from an area of high concentration of that substance to an area of low concentration of the same substance; it can be described as the spreading out of a substance. Substances that easily diffuse across the cell membrane include gases, such as oxygen and carbon dioxide.

Osmosis

Osmosis is the diffusion, or movement, of water across a semipermeable membrane, such as a cell membrane. A semipermeable membrane lets water and other solvent liquids through but nothing else. Remember, water will always try to diffuse toward the higher concentration of solutes (solids in solution).

Filtration

In filtration, some type of pressure, such as gravity or blood pressure, forces substances across a membrane that acts as a filter. Filtration separates substances in solutions. For example, you could separate sand from water by pouring the sand/water mixture through a filter. In the body, capillaries in the kidneys act as filters to separate the components of blood.

Active Transport

In active transport, substances move across the cell membrane with the help of carrier molecules, from an area of low concentration of the substance to an area of high concentration of the substance. In other words, substances are gathered together, which is the opposite of diffusion. These molecules create channels in the cell membrane or otherwise change the membrane so that large substances can pass through. Think of these carrier, or transport, molecules as tiny doormen opening the door for large substances to enter an already crowded room. Some substances that move across the cell membrane through active transport are sugars, amino acids, and potassium, calcium, and hydrogen ions.

► Cell Division

LO 21.11

Cells can become damaged, diseased, or worn out, and replacements must be made. Also, new cells are needed for normal growth. Cells reproduce by cell division, a process that involves splitting the nucleus, through **mitosis** or **meiosis**, and splitting the cytoplasm, called **cytokinesis**.

A cell that carries out its normal daily functions and is not dividing is said to be in *interphase*. For example, if a liver cell is in interphase, it is making liver enzymes, detoxifying blood, and processing nutrients. During interphase, a cell prepares for cell division by duplicating its DNA and cytoplasmic organelles. For most body cells, each daughter cell will have an exact copy of the DNA and organelles in the original mother cell. Sometimes when the DNA is duplicated, errors called *mutations* occur. These mutations will be passed on to the descendants (daughter cells) of that cell and may or may not affect the cells in harmful ways. Mutations can be simple changes in the DNA sequence or complete deletions of a gene or part of a gene. A **gene** is a discrete section of DNA that contains a code for a specific protein or function. Think about this book as a gene; a simple mutation might be a misspelled word or the loss of a sentence, a chapter, or even the whole book.

Mitosis

Following interphase, a cell may enter mitosis—a part of cell division in which the nucleus divides. During this process, the cell membrane constricts to divide the cell's cytoplasm. This causes the organelles of the original cell to be distributed almost evenly into the two new cells. The stages of mitosis are listed here and pictured in Figure 21-14.

- *Prophase* occurs when the centrioles that have replicated just prior to the onset of mitosis move to opposite ends of the cell. As they separate, they create spindle fibers between them.
- During *metaphase*, the chromosomes line up in the middle of the cell between the centrioles on these spindle fibers.
- During *anaphase*, the centromeres divide, pulling the chromatids (now chromosomes) toward the centrioles at opposite sides of the cell.
- The final stage is called *telophase*. As the chromosomes reach the centrioles, each with its complete set, cytokinesis, or division of the cytoplasm, takes place and mitosis is complete.

FIGURE 21-14 Cell mitosis.

Remember, during mitosis, the nucleus makes a complete copy of all 23 of its chromosome pairs (46 chromosomes altogether). As the cell divides, each new cell receives a complete set of chromosome pairs. The resulting cells are identical to each other.

Meiosis

Meiosis is reproductive cell division. It takes place only in the reproductive organs when the male and female sex cells are formed. During meiosis, the nucleus copies all 23 chromosome pairs, but two divisions take place. The four cells that are formed each contain only one of each chromosome pair, for a total of 23 chromosomes. This type of cell division must occur so that when the sex cells combine during fertilization, the resulting cell contains the usual number of chromosomes (46).

Go to **CONNECT** to see an animation exercise about *Meiosis* vs. *Mitosis*.

Genetic Techniques

LO 21.12

DNA is the primary component of genes and is found in the nucleus of most cells within the body. As mentioned earlier in the chapter, a gene is a section of DNA that contains the code for a specific protein or function. Genetic techniques involve using or manipulating genes.

The chemical structure of every person's DNA is the same. The unique sequence of the *nucleotides* (groups of molecules that form the basic unit of DNA) determines an individual's characteristics. As an illustration, take the statement "my cat has blue eyes." Think of each letter as one nucleotide. If you change the letter "c" in the statement to an "r" you have an entirely different statement: "my rat has blue eyes." Many genetic differences—excessively large muscles in sheep, for instance—are caused by changes in just a few nucleotides. One DNA molecule contains hundreds or thousands of genes. Each gene occupies a particular location on the DNA molecule, making it possible to compare the same gene in a number of different samples. Two widely used genetic techniques

in the clinical setting are the polymerase chain reaction (PCR) and DNA fingerprinting.

Polymerase Chain Reaction

The polymerase chain reaction (PCR) is a quick, easy method for making millions of copies of any fragment of DNA. This technique has been revolutionary in the study of genetics and has very quickly become a necessary tool for improving human health.

PCR can produce millions of gene copies from tiny amounts of DNA, even from just one cell. This method is especially useful for detecting disease-causing organisms that are impossible to culture, such as many kinds of bacteria, fungi, and viruses. For example, it can detect the AIDS virus sooner than other tests—during the first few weeks after infection. PCR is also more accurate than standard tests. The technique can detect bacterial DNA in children's middle ear fluid, which indicates an infection, even when culture methods fail to detect bacteria. Other diseases diagnosed through PCR include Lyme disease, stomach ulcers, viral meningitis, hepatitis, tuberculosis, and many sexually transmitted infections (STIs), including herpes and chlamydia.

PCR is also leading to new kinds of genetic testing because it can easily distinguish among the tiny variations in DNA that all people possess. This testing can diagnose people who have inherited disorders or who carry mutations that could be passed to their children. PCR is also used in tests that determine who may develop common disorders such as heart disease and various types of cancer. This knowledge helps individuals take steps to prevent those diseases.

DNA Fingerprinting

A DNA “fingerprint” comprises the unique sequences of nucleotides in a person's DNA and is the same for every cell, tissue, and organ of that person. Consequently, DNA fingerprinting is a reliable method for identifying and distinguishing among human beings to establish paternity and identify suspects in criminal cases (see Figure 21-15).

It is also used to diagnose genetic disorders such as cystic fibrosis, hemophilia, Huntington's disease, familial Alzheimer's, sickle cell anemia, thalassemia, and many others. Detecting genetic diseases early, or in utero, allows patients and medical staff to prepare for proper treatment. Researchers also use this information to identify DNA patterns associated with genetic diseases.

► Heredity and Common Genetic Disorders

LO 21.13

Heredity is the transfer of genetic traits from parent to child. When a sperm cell and an ovum (egg) unite, a cell called a *zygote* forms. The zygote has 46 chromosomes, or 23 chromosomal pairs. One half of each pair comes from the sperm, and the other half from the ovum. The first 22 pairs, which are the same size and shape, are called *homologous chromosomes*,

FIGURE 21-15 DNA fingerprinting can be used to establish paternity or identify a suspect in a criminal investigation.

© Martin Shields/Science Source

also known as *autosomes*. The 23rd pair are called *sex chromosomes*. If the sex chromosomes are an X chromosome and a Y chromosome, the child is a male. If the sex chromosomes are both X chromosomes, the child is a female. Although the sex chromosomes determine a child's gender, they also determine other body traits. However, the autosomes determine most body traits such as eye color or freckles.

Each chromosome possesses many genes. Homologous chromosomes carry the same genes that code for a particular trait, but the genes may be of different forms, which are called *alleles*. Many times only one allele is actually expressed as a trait, even if another allele is present. The allele that is always expressed over the other is a dominant allele. The one that is not expressed is recessive. The only way a recessive allele can be expressed is if no dominant allele is present.

Detached earlobes are an example of a trait determined by a dominant allele. If a child inherits a dominant allele for this trait from one parent but inherits the recessive allele from the other parent, the child will have detached earlobes. If the child inherits recessive alleles from both parents, then he or she will have attached earlobes. See Figure 21-16.

Most traits in the body are determined by multiple alleles. For example, hair color, height, skin tone, eye color, and body build are each determined by many different genes. *Complex inheritance* is the term that describes inherited traits that are determined by multiple genes. It explains why different children within the same family can have different characteristics.

Sex-linked traits are carried on the sex chromosomes, X and Y. The Y chromosome is much smaller than the X chromosome and does not carry many genes. So if the X chromosome carries a recessive allele, it is likely to be expressed because there is usually no corresponding allele on the Y chromosome. For example, the presence of a recessive allele that is always found on the X chromosome determines red-green color blindness. This disorder (like most sex-linked disorders) primarily affects males because the corresponding Y chromosome does not have any allele to prevent the expression of the recessive allele. Genetic influences are known to contribute to many thousands of different health conditions.

PATHOPHYSIOLOGY

LO21.14

Common Genetic Disorders

In addition to your understanding of the human body's anatomy and physiology, as a medical assistant it is very important to be able to recognize and comprehend the associated causes, characteristics, and available treatments of common genetic disorders. These genetic disorders, and their respective causes, signs and symptoms, and treatments are described here.

ALBINISM is a condition in which a person is born with little or no pigmentation in the skin, eyes, or hair. Albinism affects all races; in most cases there is no family history of it.

Causes. At least six different genes are involved with pigment production. This condition develops when a person inherits one or more faulty genes that do not produce the usual amounts of a pigment.

Signs and Symptoms. In addition to lack of pigment, people with the condition experience visual problems and sun-sensitive skin.

Treatment. Although there is no cure, treatments are available to help the symptoms. Prenatal testing for the condition is available.

CYSTIC FIBROSIS is a life-threatening disease that mainly affects the lungs and pancreas. This disease is one of the most common inherited life-threatening disorders among Caucasians in the United States.

Causes. Inheritance is autosomal recessive, so if both parents are carriers, there is a 25% chance that each child born to them will develop cystic fibrosis.

Signs and Symptoms. Patients with this disorder have increasing problems with breathing. Thick secretions eventually block passages in the airways, and these secretions may become infected.

Treatment. There is no cure, but treatments are available to help patients live with the complications associated with this disorder. Newborn babies are commonly screened for the disease because, the sooner treatment begins, the healthier the child can be. Parents are also commonly screened for the gene to determine the likelihood of having a child with cystic fibrosis.

DOWN SYNDROME, also called *trisomy 21*, is a disorder that causes intellectual disabilities and physical abnormalities.

Causes. This disorder occurs when a person has three copies of chromosome 21 instead of two. This condition can be diagnosed through prenatal tests such as amniocentesis. The risk of having a child with Down syndrome increases with the mother's age.

Signs and Symptoms. The signs of Down syndrome include a flat facial profile; a protruding tongue; oblique, slanting eyes; abundant neck skin; short, broad hands; and poor muscle tone. Heart, digestive, hearing, and visual problems are also common in people with this condition. Learning difficulties are common in Down syndrome and can range from moderate to severe.

Treatment. There is no cure, but support programs and the treatment of health problems allow many patients with Down syndrome to live a relatively normal life.

FRAGILE X SYNDROME is the most common inherited cause of learning disability. All races and ethnic groups seem to be affected equally by this syndrome.

Causes. In this disorder, one of the genes on the X chromosome is defective and makes the chromosome susceptible to breakage. This sex-linked disorder affects boys more severely than girls. It is estimated that approximately 1 in 300 females is a carrier for this disorder.

Signs and Symptoms. Mental impairment, learning disabilities, attention deficit disorder, a long face, large ears, and flat feet are some of the signs and symptoms. Fragile X syndrome can be easily diagnosed using prenatal tests such as amniocentesis.

Treatment. There is no cure, but some treatments and support groups are available to patients with this disorder.

HEMOPHILIA is a group of inheritable blood disorders. Each condition may be mild to severe.

Causes. In each type of hemophilia, an essential clotting factor is low or missing. Most types are X-linked recessive disorders; therefore, this disorder primarily affects males. Carriers of the gene can be identified with a blood test, and prenatal tests can diagnose the condition in the fetus.

Signs and Symptoms. Symptoms include easy bruising, spontaneous bleeding, and prolonged bleeding. Repeated bleeding in the joints leads to arthritis and permanent joint damage.

Treatment. Treatment includes injections of the missing clotting factors, often factor VIII.

KLINEFELTER SYNDROME is a chromosomal abnormality that affects males.

Causes. Males with this disorder have an extra X chromosome.

Signs and Symptoms. Tall stature, pear-shaped fat distribution, small testes, sparse body hair, and infertility are the most common signs and symptoms. Thyroid problems, diabetes, and osteoporosis are also common in patients with this syndrome.

Treatment. There is no cure, but treatments such as testosterone replacement therapy can decrease the risk of osteoporosis and produce more male characteristics.

PHENYLKETONURIA (PKU) develops if a person cannot synthesize the enzyme that converts phenylalanine to tyrosine. Phenylalanine is an essential amino acid, but too much of it can be harmful, so the body regularly converts it to tyrosine.

Causes. This condition is inherited as an autosomal recessive disorder.

Signs and Symptoms. If phenylalanine builds up in the blood, it can lead to irreversible damage to organs, including the brain.

Treatment. Phenylalanine is found in many proteins, so meats and other protein-rich foods must be avoided. Early detection of PKU is important to prevent developmental delays. There is no cure for PKU, but special diets allow a person to lead a normal life. Most newborns are tested for PKU, and prenatal diagnosis is available.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
21.1 Explain the importance of understanding both anatomy and physiology when studying the body.	Knowledge of anatomy (the study of the body’s structure) and physiology (the study of the body’s function) is important when learning to assign diagnosis and procedure codes and perform clinical procedures. Since the structure of an organ is related to its function, it is necessary to learn both.
21.2 Illustrate body organization from simple to more complex levels.	The body organization levels from simplest to most complex are chemical, cellular, tissue, organ, organ system, and organism.
21.3 Describe the locations and characteristics of the four main tissue types.	Epithelial tissues cover body surfaces and line body cavities or are glandular tissues. Connective tissue contains a matrix between its cells. Muscle tissue is specialized tissue that contracts and relaxes; there are three types of muscle tissue. Nervous tissue sends signals to the neurons, muscles, and glands and is located in the brain, spinal cord, and nerves.
21.4 Describe the body organ systems, their general functions, and the major organs contained in each.	The body organ systems include integumentary, skeletal, muscular, lymphatic, respiratory, digestive, nervous, endocrine, cardiovascular, urinary, and reproductive systems. Each system has its particular set of organs and vessels.
21.5 Use medical and anatomical terminology correctly.	Knowledge and use of anatomical and medical terminology are important for medical personnel to communicate with each other in a consistent manner.

LEARNING OUTCOMES	KEY POINTS
21.6 Explain anatomical position and its relationship to other anatomical positions.	In anatomical position, the body is erect, facing forward with arms at the sides and palms facing forward. All other body positions are defined based on their relation to anatomical position.
21.7 Identify the body cavities and the organs contained in each.	The dorsal cavity consists of the cranial cavity, which contains the brain, and the spinal cavity, which contains the spinal cord. The ventral cavity is composed of the thoracic cavity, the abdominal cavities, and, below the abdominal cavity, the pelvic cavity. The body's organs are contained within these cavities.
21.8 Relate a basic understanding of chemistry to its importance in studying the body.	It is important to have a basic understanding of chemistry when studying anatomy and physiology because body structures and functions result from chemical processes that occur within body cells and fluids.
21.9 Name the parts of a cell and their functions.	The main components of a cell are cell membrane, cilia, flagellum (may be present), ribosomes, endoplasmic reticulum, mitochondria, Golgi apparatus, lysosomes, and centrioles. Each has its own specialized function in the life of a cell.
21.10 Summarize how substances move across a cell membrane.	Cells use both active and passive mechanisms to transport substances across the cell membrane. Passive mechanisms include diffusion, osmosis, and filtration. Active transport uses carrier molecules.
21.11 Distinguish the stages of cell division.	A cell at rest is said to be in interphase. During mitosis, prophase, metaphase, anaphase, and telophase occur. Reproductive cell division is known as meiosis and takes place only in the reproductive cells.
21.12 Explain the uses of these genetic techniques: the polymerase chain reaction and DNA fingerprinting.	Genetic techniques allow the identification of individuals through the unique sequences of nucleotides found within DNA. Polymerase chain reactions allow millions of copies from just a fragment of DNA. DNA fingerprinting is used in paternity testing and in identifying suspects in criminal cases.
21.13 Describe the different patterns of inheritance and common genetic disorders.	Dominant traits occur through alleles. If a dominant allele is received from a parent, the trait will appear in the child. Complex inheritance is more common and is determined by multiple genes given by both parents. Sex-linked traits are carried on the sex chromosomes.
21.14 Describe the causes, signs and symptoms, and treatments of various genetic diseases and disorders.	There are many genetic disorders including albinism, cystic fibrosis, Down syndrome, Fragile X-syndrome, hemophilia, Klinefelter syndrome, and phenylketonuria. They are caused by an abnormal chromosome from one or both parents. Treatment varies and is based upon the signs and symptoms since most of these disorders do not have a cure.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall John Miller from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. What organs are found in the thoracic cavity?

2. What structure separates the thoracic and abdominopelvic cavities?

3. Mr. Miller's radiology report states that the X-ray views included an AP view. You ask the nurse practitioner what this means, and she states that the direction of the X-ray beam was from anterior to posterior. Describe, in lay terms, what that means.

EXAM PREPARATION QUESTIONS

- (LO 21.3) Which of the following are characteristics of skeletal muscle?
 - Smooth and voluntary
 - Striated and involuntary
 - Striated and voluntary
 - Smooth and involuntary
 - None of these
- (LO 21.13) The clinical name for Down syndrome is
 - Hemophilia
 - Trisomy 21
 - Klinefelter syndrome
 - Fragile X syndrome
 - Phenylketonuria
- (LO 21.5) Which word part does not change the meaning of a medical term but aids in pronunciation?
 - Word root
 - Prefix
 - Suffix
 - Combining vowel
 - All of these
- (LO 21.7) Which abdominal region is named for its location under the stomach?
 - Hypogastric
 - Epigastric
 - Hypochondriac
 - Umbilical
 - Iliac
- (LO 21.8) Acids release which type of ion in water?
 - Cl^-
 - OH^-
 - H^+
 - Na^+
 - K^+
- (LO 21.9) Which of the following organelles is responsible for protein synthesis in the cell?
 - Ribosome
 - Nucleus
 - Mitochondrion
 - Golgi apparatus
 - Centriole
- (LO 21.6) Which plane divides the body into right and left portions?
 - Transverse
 - Lateral
 - Sagittal
 - Frontal
 - Coronal
- (LO 21.5) The medical term meaning “wrist” is
 - Tarsal
 - Palmar
 - Radial
 - Brachial
 - Carpal
- (LO 21.11) An error in DNA duplication is known as a(n)
 - Mitosis
 - Mutation
 - Allele
 - DNA fingerprint
 - Chain reaction
- (LO 21.6) The term meaning “close to the point of attachment” is
 - Distal
 - Superficial
 - Medial
 - Proximal
 - Superior

MEDICAL TERMINOLOGY PRACTICE

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **append/ectomy** = append means “appendix” + ectomy means “surgical removal”

APPENDECTOMY means “surgical removal of the appendix.”

- | | | |
|-------------|-----------------|-----------------|
| 1. anterior | 7. frontal | 13. proximal |
| 2. caudal | 8. inferior | 14. sagittal |
| 3. cranial | 9. lateral | 15. superficial |
| 4. distal | 10. medial | 16. superior |
| 5. dorsal | 11. midsagittal | 17. transverse |
| 6. femoral | 12. posterior | 18. ventral |

The Integumentary System

CASE STUDY

PATIENT INFORMATION	Name	DOB	Allergies
	Christopher Matthews	11/19/19XX	NKA
PATIENT INFORMATION	Attending	MRN	Other Information
	Alexis N. Whalen, MD	324-95-786	Oldest child, one sister age 5, one brother age 6 mos. He is home-schooled by Mom.

Chris is an existing patient, age 7. Dad brings him in today, stating that Chris has been complaining that his feet “hurt and itch.” Dad adds as an aside that Chris has developed an “aversion” to soap and water and, even after showering, wears the same sneakers, often without socks, for days at a time. After taking both of them into the exam room and checking Chris’s

© McGraw-Hill Education

vital signs, you ask Chris to take off his sneakers. There is an obvious odor to his feet (and sneakers), although Chris states he showered just this morning. His feet, particularly his toes, are red, with cracking between the toes, and he is obviously uncomfortable, rubbing his bare feet together because “they itch like crazy.”

Keep Chris in mind as you study this chapter.

There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 22, you will be able to:

- 22.1** Describe the functions of skin.
- 22.2** Describe the layers of skin and the characteristics of each layer.
- 22.3** Explain the factors that affect skin color.
- 22.4** Summarize types of common skin lesions.
- 22.5** Describe the accessory organs of skin along with their structures and functions.
- 22.6** Explain the process of skin healing, including scar production.
- 22.7** Describe the common diseases and disorders of the skin.

KEY TERMS

- | | |
|----------------|-----------------|
| alopecia | melanin |
| apocrine gland | melanocyte |
| arrector pili | nail bed |
| dermis | oxygenated |
| eccrine gland | sebaceous |
| epidermis | sebum |
| follicle | stratum basale |
| hypodermis | stratum corneum |
| keratin | subcutaneous |
| keratinocyte | sudoriferous |

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.6** Compare structure and function of the human body across the life span
- I.C.7** Describe normal function of each body system
- I.C.8** Identify common pathology related to each body system including:
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe the common diseases, symptoms and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- a. Define and use entire basic structure of medical words and be able to accurately identify in the correct context, i.e. root, prefix, suffix, combinations, spelling, and definitions
- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each speciality
- d. Define and use medical abbreviations when appropriate and acceptable

► Introduction

The integumentary system consists of skin and its accessory organs. Skin is the body's outer covering and its largest organ. The accessory organs of skin are hair follicles, nails, and skin glands. Consider what you see of your own skin when you stand undressed facing a full-length mirror. In fact, pretty much everything you see in the reflection is either skin or its accessory organs. Your skin accounts for approximately 15% of your entire body weight.

► Functions of the Integumentary System

LO 22.1

People are often interested in the appearance of their skin—the color, the texture, the presence or absence of freckles, lines, wrinkles, puffiness, redness—but rarely consider its functions. The integumentary system serves many important purposes, including

- **Protection.** As long as skin is intact, it is the body's first line of defense against bacteria and viruses. It also protects underlying structures from ultraviolet (UV) radiation and dehydration.
- **Body temperature regulation.** Skin plays a major role in regulating body temperature. When a person is hot, dermal blood vessels dilate, which is why a person's skin becomes pinkish. Because the dermal blood vessels are dilated, more blood than normal passes through the skin. This is beneficial because blood carries a lot of the body's heat.

When the blood gets close to the body's surface (to skin), the heat can escape. On the other hand, if a person is cold, the dermal blood vessels constrict, preventing the heat in blood from escaping.

- **Vitamin D production.** When exposed to sunlight, the skin produces a molecule that is turned into vitamin D. The body needs vitamin D for calcium absorption.
- **Sensation.** The skin is packed with sensory receptors that can detect touch, heat, cold, and pain.
- **Excretion.** Small amounts of waste products, such as water and salts, are lost through skin when a person perspires. This is why hydration is so important when exercising or during exposure to high temperatures, as the amount of perspiration increases and higher amounts of water and salts are lost.

► Skin Structure

LO 22.2

The skin is a complex organ that consists of three layers. The **epidermis** (top layer) and the **dermis** (middle layer) sit on a third layer called the subcutaneous layer or hypodermis (see Figure 22-1).

Epidermis

The epidermis is the most superficial layer of skin. It is made up of many layers of tightly packed cells and can be divided into two major sublayers: the stratum corneum and the stratum basale.

The **stratum corneum** is the most superficial layer of the epidermis. Most of the cells in this layer are dead and very

FIGURE 22-1 Section of skin.

flat. Because they have accumulated a tough protein called **keratin**, the cells in this layer stick together and form an impermeable layer for skin. Most bacteria, viruses, and water cannot penetrate the stratum corneum.

The **stratum basale**, also known as the *stratum germinativum*, is the deepest layer of the epidermis. The cells in this layer are constantly dividing (or germinating), which pushes older cells up toward the stratum corneum.

The most common cell type in the epidermis is the **keratinocyte**. This cell makes and accumulates keratin, which makes the epidermis waterproof and resistant to bacteria and viruses. Another cell type of the epidermis is the **melanocyte**, which makes the pigment **melanin**. Melanin is deposited throughout the layers of the epidermis. This pigment absorbs UV radiation from sunlight and prevents the radiation from harming structures in the skin's underlying layers.

Dermis

Lying below the epidermis is the dermis. The **dermis** is living tissue that binds the epidermal top layer to the underlying subcutaneous tissue layer. As living tissue, the dermal layer includes all major tissue types, as well as the following:

- Epithelial, connective, muscle, and nervous tissues
- Sudoriferous (sweat) glands
- Sebaceous (oil) glands
- Hair follicles
- The arrector pili muscles
- Collagen fibers, elastin fibers, nerve fibers, and many blood vessels

Subcutaneous Layer

The **subcutaneous** layer of skin, or **hypodermis**, is largely made up of adipose and loose connective tissue. This layer also contains blood vessels and nerves. The adipose, or fat, tissue acts as a storage facility. It also cushions and insulates the underlying structures and organs. The amount of adipose tissue varies from body region to body region, and from person to person.

► Skin Color

LO 22.3

The amount of melanin in the skin's epidermis is what most determines skin color. Melanin can range in color from yellowish to brownish. The more melanin a person has in the skin, the darker the skin color. All people have about the same number of melanocytes, regardless of skin color. What varies from person to person is how active the melanocytes are in producing melanin. For example, a person with dark skin has very active melanocytes. Sunlight, UV lamps, and X-rays stimulate melanin production. This is why your skin darkens when you go to a tanning bed or to the beach for the day. Patients undergoing radiation therapy often have tanned skin in the treatment area.

As you studied in the chapter *Organization of the Body*, your inherited characteristics come from your parents. So your skin color—meaning the activity of the melanocytes—is directly related to the genes you received from your parents. As the gene pool is varied between ethnic backgrounds, it is also varied within families, which explains the differences in skin color not only among races but also within families.

Another factor that determines skin color is the amount of **oxygenated** blood in the skin's dermis. Oxygen is carried by a pigment called *hemoglobin* in the red blood cells (RBCs). *Oxygenation* refers to the amount of oxygen dissolved in the hemoglobin. Well-oxygenated hemoglobin is bright red, while poorly oxygenated hemoglobin is darker red. A person with a rich supply of oxygenated blood will have skin that is a pinkish hue. When the supply of oxygen in the blood is low, the skin looks rather pale or bluish. A bluish color of skin is called *cyanosis*.

► Skin Lesions

LO 22.4

The term *skin lesion* may be loosely defined as any variation in or on the skin (see Figure 22-2). Many of us have skin lesions; even a freckle is a lesion because it is a skin variation. Other lesions, such as ulcers and tumors, are more troublesome types of lesions. Skin lesions are classified into three major categories: primary, secondary, and vascular.

PRIMARY LESIONS

Flat, discolored, nonpalpable changes in skin color

Macule

Patch

Elevation formed by fluid in a cavity

Vesicle

Bulla

Pustule

Elevated, palpable solid masses

Papule

Plaque

Nodule

Tumor

Wheal

SECONDARY LESIONS

Loss of skin surface

Erosion

Ulcer

Excoriation

Fissure

Material on skin surface

Scale

Crust

Keloid

VASCULAR LESIONS

Cherry angioma

Telangiectasia

Petechiae

Purpura

Ecchymosis

FIGURE 22-2 Types of skin lesions.

TABLE 22-1 Common Skin Lesions and Descriptions

Lesion Name	Description
Bulla	A large blister or cluster of blisters
Cicatrix	A scar, usually inside a wound or tissue
Crust	Dried blood or pus on the skin
Ecchymosis	A black and blue mark, or bruise
Erosion	A shallow area of skin worn away by friction or pressure
Excoriation	A scratch; may be covered with dried blood
Fissure	A crack in the skin's surface
Keloid	An overgrowth of scar tissue
Macule	A flat skin discoloration, such as a freckle or a flat mole
Nodule	A large pimple or small node (larger than 6 mm)
Papule	An elevated mass similar to but smaller than a nodule
Petechiae	Pinpoint skin hemorrhages that result from bleeding disorders
Plaque	A small, flat, scaly area of skin
Purpura	Purple-red bruises, usually the result of clotting abnormalities
Pustule	An elevated (infected) lesion containing pus
Scale	Thin plaques of epithelial tissue on skin's surface
Tumor	A swelling of abnormal tissue growth
Ulcer	A wound that results from tissue loss
Verrucae	Another term for warts
Vesicle	A blister
Wheal	Another term for hive

- Primary lesions such as macules and vesicles originate from disease or body changes.
- Secondary lesions, which include ulcers and keloids, are caused by a reaction to external traumas like scratching or rubbing, the healing process, or primary lesions.
- Vascular lesions are anomalies of the blood vessels and include telangiectasias, which are small dilated blood vessels on the skin's surface, and ecchymoses, commonly called bruises.

Table 22-1 lists some of the common types of skin lesions.

► Accessory Organs

LO 22.5

The skin's accessory organs include hair follicles, **sebaceous** (oil) glands, nails, and **sudoriferous** (sweat) glands. Technically, breasts are considered an accessory organ of the integumentary system, but because they are more closely associated with the female reproductive system, they will be discussed in *The Reproductive Systems* chapter.

Hair Follicles

Hair **follicles** are tube-like structures in the skin's dermis; they are made up of epithelial tissue. Their function is to generate

FIGURE 22-3 The hair follicle extends into the dermis.

hairs (see Figure 22-3). Keratinocytes make up most of the hair follicle. As hair follicles produce new keratinocytes, old ones are pushed toward the skin's surface. The old keratinocytes stick together to produce a hair. The portion of the hair embedded in the skin is called the *root*, and the portion of the hair extending from the surface of skin is called the *shaft*.

Melanocytes are also found in hair follicles. They produce and distribute pigments to create hair color. A person develops gray hair when these melanocytes produce less pigment than normal.

When a hair follicle goes into a resting cycle, the hair falls out. Most of the time, the hair follicle will begin a growing cycle again and produce a new hair. However, sometimes hair follicles completely die, and **alopecia** (baldness) develops.

Arrector pili muscles are attached to most hair follicles. When a person is cold or nervous, these muscles pull on hair follicles and cause hairs to stand erect. These muscles also pull on fibers in the skin's dermis, causing goose bumps (see Figure 22-3).

Sudoriferous Glands

Most sudoriferous glands are located in the skin's dermis. However, their ducts open onto the skin's epidermis. There are two types of sweat glands—eccrine and apocrine.

- **Eccrine glands** are the most numerous sweat glands. They produce a watery type of sweat and are activated primarily by heat. Once sweat is deposited onto skin, it evaporates and carries heat away from the body. Eccrine sweat glands are most concentrated on the forehead, neck, and back.
- **Apocrine glands** produce a thicker type of sweat that contains more proteins than the type of sweat produced by eccrine sweat glands. Apocrine glands are most concentrated in areas of skin with coarse hair, such as the armpit and groin areas. They become active during puberty and are primarily activated by nervousness, pain, or stress, but they can also be activated by heat. Remember the last time you watched a scary movie that really frightened you? These glands were responsible for producing your cold sweat. Bacteria often break down the proteins in the sweat produced by apocrine glands.

As the proteins are digested, the bacteria release a foul-smelling waste product that is responsible for the smell of body odor.

Sebaceous Glands

Sebaceous glands—more commonly called *oil glands*—produce an oily substance called **sebum**. Sebum is secreted onto hairs to keep them soft and pliable, and it is eventually deposited onto skin to keep it soft as well. Sebum also prevents bacteria from growing on skin (see Figure 22-1).

Nails

Nails protect the ends of the fingers and toes. They are formed by epithelial cells with hard keratin, which is more permanent than the softer keratin found in your skin. For this reason, the nails must be cut because they do not slough off by themselves as your skin cells do. The portion of a nail that you can

CAUTION: HANDLE WITH CARE

Preventing and Treating Scars

One of the skin's major functions is to protect your underlying tissues from injury and infection. Whether skinning your knees as a child or cutting yourself in the kitchen while preparing food, you have most likely injured your skin at some time in your life. Your skin responds to this injury by forming a scab and then a scar. Many scars simply retract and go away in time. The size and extent of the scar depend on the following:

- *Extent of the wound.* Deep or jagged wounds may produce a larger scar.
- *Wound location.* Wounds over mobile areas like the knees and elbows often have larger scars because they are constantly under tension.

It is important that you seek medical attention for wounds that

- Bleed profusely.
- Are larger than ½ inch deep or wide.
- Are located on the face.
- Are caused by a rusty tool or nail.
- Are jagged in appearance.
- Are caused by an animal bite.
- Show signs of infection.

These basic tips may help prevent the formation of lasting scars:

- Wash wounds with mild soap and water and clean out any debris left in the wound.
- Do not use harsh soaps, hydrogen peroxide, or alcohol to clean a wound, as these can damage tissues and delay healing.
- Cover the wound to keep out bacteria, dirt, and debris to reduce the possibility of infection.

- Keep the wound moist by applying an antibiotic ointment. This keeps the bandage from sticking to the wound and may reduce the likelihood of infection.
- Do not pick or pull at a scab. This reopens the wound and may cause infection or larger scar formation.
- Use medical honey. Honey has antibacterial properties and has been found to accelerate healing. Special medical products are available for hard-to-heal wounds.

If a scar forms, numerous treatments are available:

- *Sunscreen.* Protecting a newly healed wound from UV radiation by using sunscreen with an SPF of 30 or higher helps reduce scar thickening and hyperpigmentation.
- *Silicone gel sheeting.* Studies show that covering a wound with a silicone gel sheet reduces healing time and scar formation. These sheets may be used for surgical and nonsurgical wounds.
- *Dermabrasion.* This procedure literally “sands” the surface of the skin and scar and is most often used for raised scars.
- *Surgical scar repair.* A large or hyperpigmented scar can be reduced in size by removing it surgically. Scar reduction surgical procedures include the following:
 - *Z-plasty*—a specialized plastic surgical technique that alters the pull on a tightened scar by lengthening it
 - *Scar shaving*—a technique for shaving off a raised scar
 - *Scar removal*—making an elliptical incision around the scar and removing it, which results in a scar that is thinner than the original scar

EDUCATING THE PATIENT

Cancer Warning Signs

The thought of being diagnosed with cancer is scary to everyone. Awareness of the warning signs can help patients know when to seek medical care. Always stress to patients the importance of *preventive medicine* and regular physical examinations. The American Cancer Society has put together seven cancer warning signs for adults, using the acronym **CAUTION**:

- C**—Change in bowel or bladder habits
- A**—A sore that will not heal
- U**—Unusual bleeding or discharge
- T**—Thickening or lump in the breast or elsewhere
- I**—Indigestion or difficulty with swallowing
- O**—Obvious change in a wart or mole
- N**—Nagging cough or hoarseness

see is the nail body, and the portion embedded in skin is the nail root. The nail root contains active keratinocytes that constantly divide to produce nail growth. The white, half-moon-shaped area at the base of a nail is called a *lunula*. The lunula also contains very active keratinocytes. Beneath each nail is a layer called the **nail bed**, which holds the nail down to underlying skin and provides nutrients to the nail from the blood supply under the nail bed (see Figure 22-4). Extending from the nail bed beyond the fingertip is the free edge of the nail. This is the part that you cut and file so that your nails look neat and trimmed.

► Skin Healing

LO 22.6

When skin is injured, it becomes inflamed. Redness, swelling, localized warmth, and pain are characteristics of inflammation. An inflamed area looks red because nearby blood vessels dilate. The inflamed area also swells because the dilated blood vessels “leak” and fluids seep into spaces between cells. Inflamed areas are often painful because the excess fluid activates pain receptors. However, inflammation promotes healing because more blood travels to the area, and this extra blood carries more nutrients needed for skin repair. It also carries defensive cells to clear up the cause of inflammation.

When structures and blood vessels of the dermis are injured, a blood clot initially forms. A scab, which is basically clotted blood and other dried tissue fluids, eventually replaces the blood clot. The scab is normally replaced by collagen fibers that bind the edges of the wound together. Collagen

fibers are whitish and serve as the major component of scars. Sometimes skin scars are replaced with new skin, but if the wound is extensive, a scar will persist. Scars can be merely a cosmetic nuisance, or they can cause problems with underlying structures. For example, a large scar over a joint can cause loss of movement in that joint. See the *Caution: Handle with Care* feature for more information on preventing and treating scars.

FIGURE 22-4 Anatomy of a nail.

Common Diseases and Disorders of the Skin

BURNS

Although many of the skin conditions discussed in this chapter can be extremely serious and even life-threatening (such as skin cancer), the skin is also prone to burns. In fact, burns are a leading cause of accidental death in the United States, where there are approximately 150 burn care centers devoted to this type of skin injury. Burns may be caused by heat, chemicals, electricity or radiation, as well as extreme cold or friction.

It is also important to note that an estimated 450,000 people seek medical treatment for burn injuries each year; 45,000 require hospitalization; and more than 3,500 patients die annually from burn injuries. Worldwide, more than a million people each year suffer from burn injuries that cause significant or permanent disability.

The extent of the affected body surface area and the severity (degree) of a burn are the most important factors in predicting the risk of death associated with burn injuries. The rule of nines is a quick way to estimate the extent of body surface area affected by burns. This method divides the body into 11 areas, each accounting for 9% of the total body surface. The genital area accounts for 1%. (See Figure 22-5.)

Rule of Nines. Following are the 11 body areas of the rule of nines, with their percentages:

- Head 9% (front and back, 4.5% each)
- Right arm 9% (front and back, 4.5% each)
- Left arm 9% (front and back, 4.5% each)
- Front of right leg 9%
- Front of left leg 9%
- Back of right leg 9%
- Back of left leg 9%
- Front of body 18% (both areas) trunk is two areas
- Back of body 18% (both areas) trunk is two areas
- Genital area 1%

Total body area = 100%

Burn Severity. The severity of burns indicates the thickness of the injury (see Figure 22-6). The following terms are used to report burn severity:

- *Superficial (first-degree).* These burns involve only the epidermis and are characterized by pain, redness, and

FIGURE 22-5 Using the rule of nines aids in estimating the extent of burns.

(a) First degree (superficial)

(b) Second degree (partial thickness)

(c) Third degree (full thickness)

FIGURE 22-6 The degrees of burn severity include (a) superficial (first-degree) burns, (b) partial-thickness (second-degree) burns, and (c) full-thickness (third-degree) burns.

© Sheila Terry/Science Source; © Dr. P. Marazzi/Science Source; © John Radcliffe Hospital / Science Source

swelling. Unless they are extensive, they do not require medical attention and usually heal well.

- *Partial-thickness (second-degree).* These burns involve the epidermis and dermis. Pain, redness, swelling, and blisters characterize them. Medical staff should treat any partial-thickness burn that affects 1% or more of the body surface. A body surface area of 1% is about the size of a person's hand. Shock is likely to develop in partial-thickness burn injuries that affect 9% or more of the body surface. These burns can be life-threatening, depending on their extent.
- *Full-thickness (third-degree).* These burns involve all layers of skin and often underlying structures such as muscles and bones. The skin frequently looks black or charred, which is known as *eschar*. Full-thickness burns always require medical attention regardless of the extent or the size of the burn area.

- Do not apply butter, lotions, or ointments to the burn. Only use ointments prescribed by a doctor or recommended by a pharmacist.
- Cool the burn with large amounts of cool water. Avoid ice or extremely cold water.
- Cover the burn with a sterile sheet. However, do not cover burns to the face.
- Contact emergency medical personnel for serious burns.
- With burns to the mouth and throat, check the airways for swelling. Burns to the head are always more serious than burns to other body parts. They almost always require emergency medical treatment.

Skin Cancer and Common Skin Disorders

Skin is vulnerable to many disorders because it is the most exposed of all body organs. The following sections discuss skin cancer and common skin disorders.

SKIN CANCER

Skin cancer develops from cells in the skin's epidermis. It is more common in people who have light-colored skin and who have had excessive exposure to sunlight. It can occur anywhere on the body, but it is most likely to appear on skin that is readily exposed to sunlight. The two most common types of skin cancer

General Guidelines for Treating Burns.

- Anything sticking to the burn should be left in place.

(a)

(b)

(c)

FIGURE 22-7 Types of skin cancer: (a) squamous cell carcinoma, (b) basal cell carcinoma, and (c) malignant melanoma.

© Dr. P. Marazzi / Science Source; © Dr. P. Marazzi / Science Source; © Dr. P. Marazzi / Science Source

are basal cell carcinoma and squamous cell carcinoma, but the most deadly type is malignant melanoma (see Figure 22-7). For more information on the general symptoms of cancer, refer to the feature *Educating the Patient*.

BASAL CELL CARCINOMA accounts for approximately 90% of all skin cancers in the United States. Fortunately, it progresses slowly and rarely spreads to other body parts. It is derived from cells of the stratum basale of the epidermis.

Signs and Symptoms. These include changes on the skin and a new growth or sore on the skin that does not heal. Its appearance may be waxy, smooth, red, pale, flat, or lumpy, and it may or may not bleed.

Treatment. Several forms of treatment are available:

- *Curettage and electrodesiccation.* In curettage, a sharp instrument is used to scoop out the cancerous lesion. Electrodesiccation uses electrical currents to minimize bleeding as well as to kill any remaining cancer cells.
- *Mohs surgery.* The cancerous lesion is shaved off one layer at a time. Each layer is then examined under a microscope by the surgeon until no tumor is detected in the last layer removed.
- *Cryosurgery.* Freezing is used to kill cancer cells.
- *Laser therapy.* A beam of light destroys cancer cells.

SQUAMOUS CELL CARCINOMA is much less common than basal cell carcinoma but is more likely to spread to surrounding tissues. It arises from flat cells of the epidermis and is most likely to appear on the face, lips, ears, and the backs of the hands. The signs and symptoms of and the treatments for this type of cancer are the same as for basal cell carcinoma.

MALIGNANT MELANOMA, a cancer that arises from melanocytes, is the most aggressive of the skin cancers. It is also the fastest-growing skin cancer, with rates increasing 5% to 7% per year. The lifetime risk of developing malignant melanoma is 1 in 75. It appears to be more prevalent in females, but males, when diagnosed, seem to have a poorer prognosis. Melanoma can occur anywhere on the body but most often appears on the trunk, head, and neck in men and on the arms and legs in women.

Signs and Symptoms. A mole that itches or bleeds is a common symptom. New moles may develop near it, or it may change to have any signs of the ABCDE rule:

- *Asymmetry.* The mole should not be asymmetrical. It should look equal in size from side to side.
- *Border.* The border of the mole should not be irregular. The edges should not blur into nearby normal tissue.
- *Color.* The mole should be even. It should not darken or lighten or contain a mixture of colors.
- *Diameter.* The mole should not grow larger than 6 mm, about the diameter of a pencil eraser.
- *Evolving.* The mole has been changing in size, shape, color, or appearance or growing in an area of previously normal skin. In an existing mole, the texture of the mole may change and become hard, lumpy, or scaly. Although the skin may feel different and may itch, ooze, or bleed, melanoma usually does not cause pain.

Treatment. The treatment depends on the staging of this cancer. Melanoma has five stages, including the following, from the least to the most serious:

- Stage 0. Malignancy is found only in the epidermis.
- Stage I. Malignancy has spread from the epidermis to the dermis and has a thickness of 1 to 2 millimeters.
- Stage II. Malignancy has a thickness of 2 to 4 millimeters and may be ulcerated.
- Stage III. Malignancy has spread to one or more nearby lymph nodes.
- Stage IV. Malignancy has spread to other body organs or other lymph nodes far away from the original melanoma site.

Available treatments for melanoma include the following:

- Surgery to remove the melanoma
- Lymph node biopsy to determine if the cancer has spread
- Removal of cancerous lymph nodes
- Chemotherapy for advanced stages of cancer
- Radiation therapy for advanced stages of cancer
- Immunotherapy to boost the patient's immune system

Common Skin and Hair Disorders

ACNE VULGARIS, commonly known as acne, is an inflammatory condition of the skin follicles and sebaceous glands. See Figure 22-8.

Causes. Acne often appears in adolescence as a result of a surge of sex hormones, which increases the amount of sebum the sebaceous glands produce. Excess sebum and dead skin cells clog the pores, where bacteria then accumulate, causing the pimples. These pimples may rupture or leak, and as the bacteria then infect the adjacent skin areas, they cause the characteristic skin inflammation.

Signs and Symptoms. Comedos (blackheads and whiteheads), as well as papules and pustules occur mainly on the face, but they can also occur on the neck, back, and chest.

Treatment. Patients may find the following instructions helpful in controlling their acne. Wash your face twice a day, removing all makeup and using *noncomedogenic* (non-pore-clogging)

FIGURE 22-8 Acne is common during adolescence and is frequently seen on the face and back.

© McGraw-Hill Education

skin care products. Wash your hair frequently because oils from your hair can end up on your face. Always use makeup or lotions containing sunscreen, and keep your hands away from your face during the day. Seek the care of a dermatologist for severe cases of acne, as these may require oral antibiotics (tetracycline) or other prescription medications, such as retinol.

ALOPECIA is a disorder that specifically targets hair and results in hair loss.

Causes. Most of the time, alopecia is inherited. Other common causes include hormonal changes, chemotherapy, stress, burns, and fungal infections of the skin.

Signs and Symptoms. Loss or lack of hair on the scalp or other areas of the body, alopecia is more commonly called *baldness*.

Treatment. If a result of heredity, this disorder is not curable. Hair transplants and some drugs, such as Rogaine®, may slow down hair loss. Hair loss caused by other factors, such as chemotherapy, is often temporary, but the hair may grow back a different color or texture.

CELLULITIS is an inflammation of connective tissue in skin and primarily occurs on the face and legs. See Figure 22-9.

Causes. This skin disease is caused by staphylococcal and streptococcal bacteria.

Signs and Symptoms. Skin appears red and tight and is often painful. The inflammation may trigger a fever.

Treatment. Treatment includes oral and topical antibiotics. In serious cases, intravenous (IV) antibiotics and hospitalization may be required.

DERMATITIS is a general term defined as inflammation of skin or a rash. It has many causes and is a sign of many types of skin disorders. A common type of dermatitis is contact dermatitis, which results from contact with allergens or irritants. If you have ever had poison ivy, you had a type of contact dermatitis. Another common form of dermatitis is eczema.

ECZEMA is one type of chronic dermatitis that has acute phases characterized by a blistered rash that itches severely. Eczema often appears in childhood but is also commonly seen in adults.

FIGURE 22-9 Cellulitis is inflammation of the skin caused by staphylococcal or streptococcal bacteria.
CDC/Allen W Mathies, MD, California EPO, Immunization Branch

Causes. Causes of eczema are mostly unknown, but it is thought to be a type of allergy or the result of an often unknown underlying inflammatory condition. Environmental irritants, stress, diet, and medications can exacerbate or worsen the signs and symptoms of this disease.

Signs and Symptoms. The rashes of eczema are red, scaly, and itchy.

Treatment. Treatments include topical steroids and other types of anti-inflammatory drugs. Antibiotics may be needed for any secondary infections that develop. Avoiding known factors that trigger eczema, such as stress, is also helpful.

FOLLICULITIS, sometimes called “swimmer’s rash,” is an inflammation of hair follicles. See Figure 22-10.

Causes. This disorder usually results from shaving or excess rubbing of skin areas. It may also be caused by bacteria and fungi, which may develop from prolonged wearing of wet swimwear or using undertreated hot tubs.

Signs and Symptoms. Follicles become red and itchy and often look like pimples.

Treatment. Treatments include regular cleansing of skin, topical antibiotics, and the use of electric razors instead of razor blades. Wearing wet swimwear for prolonged periods of time should also be avoided.

HERPES SIMPLEX types 1 and 2 are the most common types of herpes simplex.

Causes. Herpes simplex types 1 and 2 are both caused by a virus. Herpes simplex type 1 causes cold sores. It is very

FIGURE 22-10 Folliculitis can be caused from shaving or rubbing of the skin and often looks like pimples.
© McGraw-Hill Education

FIGURE 22-11 Herpes zoster, more commonly known as shingles, is a painful, blistering rash that follows the pathway of an affected nerve root. CDC

contagious and is spread through saliva. Herpes simplex type 2, known as *genital herpes*, is sexually transmitted.

Signs and Symptoms. Herpes simplex type 1 causes painful sores on the lips, mouth, and face. Herpes simplex type 2 normally causes painful sores on genital areas.

Treatment. There is no cure for herpes simplex, and its skin lesions usually recur throughout life. However, antiviral drugs such as acyclovir (Zovirax®) prevent frequent outbreaks. Patients should also be instructed to get adequate rest and nutrition and to control stress as much as possible.

HERPES ZOSTER is a disorder commonly known as *shingles*. See Figure 22-11.

Causes. Herpes zoster is caused by the *Varicella* virus, which also causes chickenpox. After a person has chickenpox, the virus becomes dormant in the spine's dorsal nerve root but can become active again later in life to cause shingles.

Signs and Symptoms. Herpes zoster causes a painful, blistering rash usually on one side of the body following the *dermatome*—the skin area along the pathway of the affected nerve root. Shingles usually starts as a tingling or pain on the torso or neck, followed by a rash that eventually blisters.

Treatment. Some antiviral medications, such as Zovirax®, shorten the duration of the disease, and pain medications assist with pain control. Recovery is usually complete, but recurrences of the disease do occur. Some patients suffer from the complication known as *post-herpetic pain syndrome*, where nerve pain continues even though the rash is no longer present. It is uncertain whether the chickenpox vaccine prevents herpes zoster. The vaccine Zostavax® by Merck Pharmaceuticals is a preventive alternative for patients 60 years of age and older with a history of having had chickenpox. Patients considering Zostavax® should know that it is advertised as reducing the risk of developing shingles; it does not guarantee that shingles will not occur.

IMPETIGO causes the formation of oozing skin lesions that eventually crust over. It is highly contagious for those who come in contact with the lesions or the exudates (exuded substances) from them.

Causes. This disease is caused by staphylococcal and streptococcal bacteria.

Signs and Symptoms. The skin develops itchy, oozing lesions that eventually crust over with a distinctive, honey-colored crust from the drying exudates.

Treatment. This condition is treated with antibiotics. Washing the lesions two or three times a day with soap and water will help remove the exudates and decrease the spread to other skin areas.

PEDICULOSIS is more commonly known as *lice* and comes in three forms: head lice (*Pediculosis capitis*), body lice (*Pediculosis corporis*), and pubic lice (*Pediculosis pubis*).

Causes. All forms are caused by parasitic lice and are associated with overcrowded conditions causing person-to-person contact. Pubic lice are also spread by sexual contact.

Signs and Symptoms. Skin itches and can become irritated from scratching. Head lice are also identifiable by the dandruff-like nits that cannot be shaken off.

Treatment Prescription medications and shampoos are often necessary. For head lice, some patients find equal success with over-the-counter (OTC) treatments such as Nix®.

PSORIASIS is a common chronic, inflammatory skin condition.

Causes. This skin disorder is most likely an inherited autoimmune disorder.

Signs and Symptoms. Patients with psoriasis have recurring episodes of itching and redness with outbreaks of distinctive silvery, scaly skin lesions. Some people also have joint pain with this condition known as psoriatic arthritis.

Treatment. Mild cases are treated with anti-inflammatory drugs and therapeutic ointments such as creams with vitamins A and D, hydrocortisone creams, and retinoids. Some patients also experience relief with controlled UV ray treatments. Severe cases may require hospitalization.

RINGWORM is a fungal skin infection, commonly occurring in three forms: *Tinea corporis* (body), *Tinea capitis* (scalp), and *Tinea pedis* (feet), which is commonly known as athlete's foot. See Figure 22-12.

Causes. All forms of ringworm are caused by fungi called *dermatophytes*.

Signs and Symptoms. Flat, circular lesions that may be dry and scaly or moist and crusty are the hallmarks of ringworm. *Tinea capitis* is characterized by small papules that may cause small, patchy areas of baldness.

Treatment. Topical and oral antifungal agents are used to treat all forms of ringworm. The spread is contained by not sharing sheets, towels, and other personal care items.

ROSACEA is a skin disorder that commonly appears as facial redness, predominantly over the cheeks and nose.

Causes. Rosacea results from dilation of small facial blood vessels, but the cause of this dilation is unknown. It occurs most frequently in fair-skinned people.

Signs and Symptoms. Redness and acne-like symptoms on the face are the most common symptoms.

Treatment. Although it is not curable, rosacea is usually managed well with topical cortisone or antibiotic creams. In severe cases, electrolysis may be useful in destroying large or dilated blood vessels.

(a) *Tinea corporis* affects the body.

(b) *Tinea capitis* affects the scalp.

(c) *Tinea pedis* affects the feet.

FIGURE 22-12 Ringworm is a fungal infection that affects the body in three places.

CDC/Dr. Lucille K. Georg; CDC; carroteater/Getty Images RF

SCABIES is a highly contagious skin condition.

Causes. Scabies is caused by an itch mite that burrows beneath skin and lays its eggs. Sometimes the burrows of the mites can be seen and look like red pencil marks.

Signs and Symptoms. Redness and severe itching, especially at night, are usually the only symptoms of scabies.

Treatment. Most cases are easily treated with prescription medications such as Elimate™, which is left on the skin for 6 to 10 hours and followed by a bath. Antipyretic (anti-itching) or steroid creams may control the itching. Because scabies is

contagious, it is wise to treat an entire family if one member is infected.

WARTS (verrucae) are harmless skin growths that can appear almost anywhere on the body surface but most commonly occur on the hands, feet, and face.

Causes. These growths are caused by a virus.

Signs and Symptoms. Warts vary greatly in appearance; they can be smooth, flat, rough, raised, dark, small, or large.

Treatment. Warts are often removed with OTC medications but can also be treated through surgery, lasers, freezing, or burning.

SUMMARY OF LEARNING OUTCOMES	
LEARNING OUTCOMES	KEY POINTS
22.1 Describe the functions of skin.	The functions of skin include protection, body temperature regulation, vitamin D production, sensation, and excretion.
22.2 Describe the layers of skin and the characteristics of each layer.	The topmost layer of the skin is the epidermis. The dermis is the complex middle layer. The innermost layer attaching the skin to muscle is the subcutaneous layer.
22.3 Explain the factors that affect skin color.	The amount of melanin affects and determines skin color. The amount of oxygen-carrying hemoglobin in the blood also affects skin color.
22.4 Summarize types of common skin lesions.	Skin lesions are split among three main types: primary lesions such as macules and vesicles; secondary lesions, which include ulcers and keloids; and vascular lesions, which involve blood vessels and include telangiectasias and ecchymoses.
22.5 Describe the accessory organs of skin along with their structures and functions.	The accessory organs of skin include hair follicles, arrector pili muscles, sebaceous glands, sudoriferous glands, and keratin-filled nails.
22.6 Explain the process of skin healing, including scar production.	Injured skin becomes inflamed from dilating blood vessels that leak and cause swelling. A blood clot is formed, which is replaced by a scab, which is then replaced by collagen fibers that produce scar tissue.
22.7 Describe the common diseases and disorders of the skin.	Common diseases and disorders of the skin include acne, alopecia, cellulitis, dermatitis, eczema, folliculitis, herpes simplex, herpes zoster, impetigo, pediculosis, psoriasis, ringworm, rosacea, scabies, and warts.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall Chris Matthews from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. Considering the information you already have on Chris's feet and his behavior, what is the likely diagnosis?
2. What is the clinical name for this condition? During and after treatment, what are some tips you can give Chris to avoid a recurrence?

EXAM PREPARATION QUESTIONS

1. (LO 22.2) Which protein gives skin its protective quality?
 - a. Melanin
 - b. Vitamin D
 - c. Keratin
 - d. Hemoglobin
 - e. Collagen
2. (LO 22.4) Which of the following lesions is a vascular lesion?
 - a. Tumor
 - b. Macule
 - c. Ecchymosis
 - d. Wheal
 - e. Plaque
3. (LO 22.7) The patient has burned his left arm front and back from elbow to fingertips as well as his left chest and abdomen (approximately half of his trunk). Using the rule of nines, what percentage of his body is burned?
 - a. 27%
 - b. 18%
 - c. 13.5%
 - d. 9.5%
 - e. 22.5%
4. (LO 22.5) The medical term for hair loss is
 - a. Folliculitis
 - b. Alopecia
 - c. Pediculosis
 - d. Impetigo
 - e. Excoriation
5. (LO 22.4) Which medical condition is more commonly known as a *hive*?
 - a. Cicatrix
 - b. Vesicle
 - c. Pustule
 - d. Wheal
 - e. Erosion
6. (LO 22.4) *Verrucae* is a medical term meaning
 - a. Bruises
 - b. Warts
 - c. Nodules
 - d. Wrinkles
 - e. Moles
7. (LO 22.1) Which of the following is *not* a function of skin?
 - a. Temperature regulation
 - b. Protection
 - c. Excretion
 - d. Sensation
 - e. Vitamin B production
8. (LO 22.7) Scabies is caused by
 - a. Fungi
 - b. Lice
 - c. Mites
 - d. Bed bugs
 - e. Bacteria
9. (LO 22.2) The most superficial layer of the epidermis is the
 - a. Stratum basale
 - b. Stratum corneum
 - c. Stratum germinativum
 - d. Stratum dermis
 - e. Stratum keratin
10. (LO 22.5) The part of the nail that holds it down to the underlying tissues and provides nutrients to the nail is the
 - a. Lunula
 - b. Nail bed
 - c. Cuticle
 - d. Free edge
 - e. Nail root

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **chemo/therapy** = chemo means “chemical” + therapy means “treatment”

CHEMOTHERAPY means “treatment with chemicals.”

1. cellulitis
2. cyanosis
3. dermatitis
4. dermatome
5. epidermis

6. folliculitis
7. hemoglobin
8. hypodermis
9. keratinocyte
10. lunula

11. melanocyte
12. pediculosis
13. sebaceous
14. subcutaneous
15. sudoriferous

The Skeletal System

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	John Miller	12/5/19XX	Bee Stings
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	082-09-981	X-Ray Report: AP and lateral knee films show no fractures. Joint alignment is normal.

John Miller is a 65-year-old patient returning to the clinic for a follow-up visit. He has a history of hypertension, diabetes Type 2, myocardial infarction (heart attack, 2008), and a recent confirmed diagnosis of congestive heart failure. He is taking glyburide, captopril, and HCTZ. When he arrives at the clinic, you notice he is walking with difficulty. He is seeing Olivia Ntombi, FNP, today as a work-in patient, since Dr. Buckwalter's schedule is fully booked. Mr. Miller states, "I was doing okay until I fell down yesterday. I was carrying

© McGraw-Hill Education

a box of stuff to take to the Salvation Army and lost my footing." The patient shows you an abrasion on his left knee and his right elbow. He says his knee is popping and very tender, and his elbow does not bend as much as it did before he fell. He is concerned that the bursitis in his knee might flare up. He also wonders why his elbow does not bend. The nurse

practitioner orders X-rays of his knee and elbow.

Keep John in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 23, you will be able to:

- 23.1** Describe the structure of bone tissue.
- 23.2** Explain the functions of bones.
- 23.3** Compare intramembranous and endochondral ossification.
- 23.4** Describe the skeletal structures and one location of each structure.
- 23.5** Locate the bones of the skull.
- 23.6** Locate the bones of the spinal column.
- 23.7** Locate the bones of the rib cage.
- 23.8** Locate the bones of the shoulders, arms, and hands.
- 23.9** Locate the bones of the hips, legs, and feet.
- 23.10** Describe the three major types of joints and give examples of each.
- 23.11** Describe the common diseases and disorders of the skeletal system.

KEY TERMS

appendicular	patella
articulations	pectoral girdle
axial	pelvic girdle
clavicle	radius
diaphysis	scapula
dislocation	sternum
epiphysis	suture
femur	temporal mandibular joint (TMJ)
fibula	tibia
metacarpal	ulna
metatarsal	
ossification	

- I.C.1** Describe structural organization of the human body
- I.C.6** Compare structure and function of the human body across the life span
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including:
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define both medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty

► Introduction

Imagine that you are walking along a bustling city sidewalk, and someone behind you calls your name. As you pause and turn your head to see who it is, you catch a glimpse of your profile in the reflection of a coffee shop window. You stand taller than you think you are, with one leg in front of the other as if pivoting. You bring your right hand up to your forehead and quickly rub your brow, then let it drop to your side. Your friend then appears beside you and the two of you hug. Although it may seem as if your body is simply made of only the surface features you can see reflected in this window, dressed for the day in nice clothing and hugging your friend, of course, there is much more to this picture. After all, your bones are behind this picture, scattered all throughout your body to provide it with the structure and support you need for daily functioning.

In this chapter, you will learn about the bones of the body, their structure, and how the joints of the body work. The skeletal system is composed of 206 bones as well as joints and related connective tissues. Now, picture this many bones hiding within that person—*you!*—reflected earlier in the coffee shop window.

The skeleton has two major divisions—the **axial** skeleton and the **appendicular** skeleton (see Figure 23-1). These divisions differ in the following ways:

- The axial skeleton contains 80 bones, including the bones of the skull, vertebral column, and rib cage. It supports the head, neck, and trunk, and it protects the brain, spinal cord, and organs in the thorax. The hyoid bone, which anchors the tongue, is also included in the axial skeleton.

- The body's other 126 bones belong to the appendicular skeleton, which includes the bones of the arms, legs, **pectoral girdle**, and **pelvic girdle**. The pectoral girdle attaches the arms to the axial skeleton, and the pelvic girdle attaches the legs to the axial skeleton.

► Bone Structure

LO 23.1

Bones contain various kinds of tissues, including osseous tissue, blood vessels, and nerves. Osseous tissue can be compact or spongy (see Figure 23-2). At the microscopic level, spongy, or cancellous, bone has more spaces within it than compact bone does. Spongy bone looks a lot like a natural sea sponge with the spaces filled with *red bone marrow*. Compact bone looks solid, like granite or marble. However, the following structures within these bones can be observed with a microscope:

- *Osteons*, also known as the *Haversian system*, are elongated cylinders that run up and down the bone's long axis. Each osteon has a central canal that contains blood vessels and nerves.
- *Bone matrix*, made of inorganic salts, collagen fibers, and proteins, is the substance between bone cells. Bone cells are called *osteocytes*. The primary salt of the matrix is calcium phosphate, which makes bone matrix very hard.
- *Lamellae* are layers of bone surrounding the canals of osteons.
- *Lacunae* are holes in the matrix of bone that hold osteocytes.

FIGURE 23-1 Major bones of the skeleton: (a) anterior view and (b) posterior view. The axial skeleton is shown in orange and the appendicular skeleton is shown in yellow.

FIGURE 23-2 Cross section of bone showing compact and cancellous (spongy) bone tissue.

© Lester V. Bergman/Corbis

- *Canaliculi* are tiny canals that connect lacunae to each other and allow osteocytes to spread nutrients to each other.

All bones are made up of both compact and cancellous bone. They are classified according to their shape (see Figure 23-3):

- *Long bones* are located primarily in the arms and legs. Examples include the **femur** (thighbone, see Figure 23-4) and the humerus (upper arm bone). Long bones have the following parts (see Figure 23-5):
 - **Diaphysis**—the shaft of a long bone. It is tubular and consists of a thick collar of compact bone that surrounds the central medullary cavity.
 - **Epiphysis**—the expanded end of a long bone. It consists of a thin layer of compact bone surrounding cancellous bone. Long bones have an epiphysis at both ends.

FIGURE 23-3 Classification of bone by shape: Five different classes of bone are recognized according to shape—long, short, flat, irregular, and sesamoid.

- **Articular cartilage**—the cartilage that covers the epiphyses of long bones. It cushions bones and absorbs stress during bone movements.
- **Medullary cavity**—the canal that runs through the center of the diaphysis. In adults, it contains **yellow bone marrow** (mostly fat).
 - **Periosteum**—a membrane that surrounds the diaphysis. It contains bone-forming cells, dense fibrous connective tissue, nerves, and blood vessels.
 - **Endosteum**—a membrane that lines the medullary cavity and the holes of cancellous bone. It contains bone-forming cells.
- **Short bones** are located in the wrists and ankles. Examples include the carpals (wrist bones) and some of the tarsals (ankle bones).
- **Flat bones** are primarily located in the skull and rib cage. Examples include the ribs and frontal bone.
- **Irregular bones** include the vertebrae and the pelvic girdle bones.
- **Sesamoid bones** are small, rounded bones usually found next to joints or embedded in a tendon. An example is the patella, or kneecap.

Gender Differences in Skeletal Structure

You may wonder how physicians, pathologists, and archeologists can tell if a skeleton is male or female. Table 23-1 outlines some of the skeletal differences between the sexes.

► Functions of Bones

LO 23.2

Bones have many functions. Without bones, the body would be more like a glob of jelly and not capable of very much. Bones give shape to body parts such as the head, legs, arms, and trunk. They also support and protect soft structures in the body. For example, the skull protects the brain. Bones also function in body movement because skeletal muscles attach to them, allowing you to create willful, or voluntary, movements.

The red marrow within cancellous bone produces new blood cells in a process called **hematopoiesis**. Blood cells have a limited lifespan, so they need to be replaced. Red blood cells, for example, need replacing as often as every 90 to 120 days. Your red marrow is actively making more blood cells 24 hours a day. Bones also store calcium for the body. Every cell in the body needs calcium, so the body must have a large supply readily available.

► Bone Growth

LO 23.3

Bones grow through a process called **ossification**. Ossification is the process of creating bone from either fibrous membranes or cartilage. These two types of ossification are called intramembranous and endochondral ossification.

In **intramembranous** ossification, bones begin as tough, fibrous membranes. Eventually, bone-forming cells called **osteoblasts** turn the membrane to bone. Except for the lower jaw bone, the bones of the skull are formed by intramembranous ossification.

In **endochondral** ossification, bones start out as cartilage models. Eventually, the osteoblasts form a bone collar around the diaphysis of the cartilage model. Think of a sculptor who first builds a framework or model of soft material before applying sculpting clay over the framework. Eventually, when the clay hardens, either through drying or firing in a kiln, there is more hard material than there is soft framework. Then bone is formed in the diaphysis of the bone. This area is called the **primary ossification center**. Later, the epiphyses turn to bone (secondary ossification centers), and the medullary cavity and spaces in cancellous bone are formed. The cells that form holes in bone are called **osteoclasts**. As long as a bone contains some cartilage between an epiphysis and the diaphysis, it can continue to grow in length. This plate of cartilage is called an **epiphyseal disk** or **growth plate**. Once the cartilage is gone, bone growth stops. For most people, bone growth stops between the ages of 18 and 25.

Even after bone growth stops, osteoclasts and osteoblasts continually remodel bone tissue. Throughout life, osteoclasts break down bone when the body needs more calcium in the blood, and osteoblasts replace the bone when there is excess calcium in the blood.

FIGURE 23-4 Bone structures: (a) bone structures of the femur and (b) bone structures of the tibia and fibula.

Building Better Bones

Many factors influence bone health, including diet, exercise, and a person's overall lifestyle. You can help patients improve or maintain their bone health by teaching them about behaviors that will support it.

Bone-Healthy Diet Good nutrition is essential for proper bone growth during childhood and the teen years. It is equally important in adulthood in order to maintain healthy bones. Bone-building nutrients are found in dairy products, broccoli, kale, spinach, salmon, sardines, egg yolks, whole grains, and fruits—especially bananas and oranges. Calcium and vitamin D are particularly important for healthy bones. Without vitamin D, the bloodstream cannot absorb calcium from the digestive tract. Without calcium, bone tissue will slowly wear away. Supplements can always be taken if a person's diet does not include adequate amounts of calcium and vitamin D.

Bone-Healthy Exercises Weight-bearing and strength-training exercises are best for bone health. When your muscles contract, they pull on your bones. This tension stimulates bones to thicken and strengthen. Lifting weights is an effective way to increase the tension on bones. Other activities such as jogging, walking briskly, or playing a sport regularly will also stimulate your bones to increase in density.

Bone-Healthy Lifestyle A person with a bone-healthy lifestyle avoids smoking and alcohol. Smoking rids the body of calcium, which is necessary for bone growth. Alcohol prevents calcium absorption in the digestive tract. Smokers are almost twice as likely to develop osteoporosis as nonsmokers.

Bone Tests

Bone density tests and bone scans are currently the most useful tools in determining bone health. Bone density tests are

FIGURE 23-5 Parts of a long bone.

painless procedures used to determine the density of a person's bones. Because osteoporosis shows no symptoms in early stages, it is important to have these tests done when your doctor recommends them. Bone scans help diagnose the causes of bone pain, arthritis, bone infections, and bone cancers. These scans use radioactive tracers that are injected into the patient and concentrate in bone tissue.

► Bony Structures

LO 23.4

The skeletal bones act as your body's rigid foundation. By design, they are not perfectly smooth or perfectly rounded.

Bones have projections and processes for muscle and ligament attachment. For bones to come together at joints, or **articulations**, there are depressions and hollows. In addition, blood vessels and nerves need openings within bones for entrances and exits. Each of these structures has a specific name and design. Table 23-2 lists some of these common terms to describe skeletal structures and directs you to the appropriate figures throughout this chapter.

► The Skull

LO 23.5

Skull bones are divided into two types: cranial and facial bones. Cranial bones form the top, sides, and back of the skull (see Figure 23-6). Facial bones form the face (see Figure 23-7). The skull bones of an infant are not completely formed. The “soft spots” felt on an infant's skull are actually *fontanels*, which are tough membranes that connect the incompletely developed bones. These structures allow the infant's skull to be somewhat moldable to assist with delivery through the birth canal. As the fontanels close, the sutures of the skull are formed.

The major cranial bones are the following:

- The *frontal bone* forms the anterior portion of the cranium. It is also called the forehead bone.
- *Parietal bones* form most of the top and sides of the skull.
- The *occipital bone* forms the back of the skull. The large hole at the base of the occipital bone is called the *foramen magnum*. It allows the spinal cord to connect to the brain. Two bumps called occipital *condyles* are on either side of the foramen magnum. They sit on top of the first vertebra. When you nod your head, your occipital condyles are rocking back and forth on the first vertebra of the spinal column.
- Two *temporal bones* form the lower sides of the skull.
 - A canal called the *external auditory meatus* (commonly called the ear canal) runs through each temporal bone. A large bump called the *mastoid process* is located on each temporal bone just behind each ear. Major neck muscles attach to your skull at the mastoid processes.
 - A *sphenoid bone* forms part of the floor of the cranium. It is shaped like a butterfly. In the center is a deep depression called the *sella turcica*. The pituitary gland sits in this deep depression.

TABLE 23-1 Differences Between the Male and Female Skeletons

Part	Differences
Skull	Male skull is larger and heavier, with more conspicuous muscular attachments. Male forehead is shorter, facial area is less round, jaw is larger, and mastoid processes are more prominent than those of a female.
Pelvis	Male pelvic bones are heavier, thicker, and have more obvious muscular attachments. The obturator foramina and the acetabula are larger and closer together than those of a female.
Pelvic cavity	Male pelvic cavity is narrower in all diameters and is longer, less roomy, and more funnel-shaped. The distances between the ischial spines and between the ischial tuberosities are less than in a female.
Sacrum	Male sacrum is narrower, sacral promontory projects forward to a greater degree, and sacral curvature is bent less sharply posteriorly than in a female.
Coccyx	Male coccyx is less movable than that of a female.

TABLE 23-2 Terms Used to Describe Skeletal Structures

Term	Definition	Examples
Condyle	A rounded process that usually articulates with another bone	Medial and lateral condyles of the femur (see Figure 23-4a)
Crest	A narrow, ridge-like projection	Iliac crest of the ilium (see Figure 23-11)
Epicondyle	A projection situated above a condyle	Medial epicondyle of the femur (see Figure 23-4a)
Foramen	An opening through a bone that is usually a passageway for blood vessels, nerves, or ligaments	Mental foramen of the mandible (see Figure 23-7)
Fossa	A relatively deep pit or depression	Olecranon fossa of the humerus (see Figure 23-10d)
Head	An enlargement on the end of a bone	Head of the femur (see Figure 23-4a)
Process	A prominent projection on a bone	Mastoid process of the temporal bone (see Figure 23-6)
Suture	An interlocking line of union between bones	Lambdoidal suture between the occipital and parietal bones (see Figure 23-6)
Trochanter	A relatively large process	Greater trochanter of the femur (see Figure 23-4a)
Tubercle	A small, knob-like process	Greater tubercle of the humerus (see Figure 23-10b)
Tuberosity	A knob-like process usually larger than a tubercle	Tibial tuberosity of the tibia (see Figure 23-4b)

**FIGURE 23-6** Lateral view of the skull.

- *Ethmoid bones* are between the sphenoid bone and the nasal bones. They also form part of the floor of the cranium.
- *Ear ossicles* are the body's smallest bones. They are the malleus, incus, and stapes and are in the middle ear cavities of the temporal bones.

The following are major facial bones:

- The *mandible* is the lower jaw bone and is the only movable bone in the skull. It attaches to the temporal bone in front of the external auditory meatus in an area known as the **temporal mandibular joint (TMJ)**. The mandible anchors the lower teeth and forms the chin.
- The *maxillae* form the upper jaw bone of the facial skeleton, to which the upper teeth anchor.
- The *zygomatic bones* are the cheekbones. Several thin nasal bones fuse together to form the bridge of the nose.
- *Palatine bones* form the hard palate, which is the roof of the mouth.
- The *vomer* is a thin bone that divides the nasal cavity.

FIGURE 23-7 Anterior view of the skull.

► The Spinal Column

LO 23.6

The spinal column consists of 7 cervical vertebrae, 12 thoracic vertebrae, 5 lumbar vertebrae, a sacrum, and a coccyx (see Figure 23-8 and Table 23-3):

- *Cervical vertebrae*, which are located in the neck, are the smallest and lightest vertebrae. The first cervical vertebra is called the *atlas* and the second is called the *axis*. When you turn your head from side to side, your atlas is pivoting around your axis.
- *Thoracic vertebrae* are the posterior attachment for the 12 pairs of ribs. They have long, sharp spinous processes that you can feel when you run your finger down someone's spine.
- *Lumbar vertebrae* are very sturdy structures. They form the small of the back and bear the most weight of all the vertebrae.

TABLE 23-3 The Spinal Column

Vertebrae Name	Number	Description
Cervical	7	Smallest and lightest
Thoracic	12	Posterior attachments for ribs
Lumbar	5	Form the small of the back
Sacrum	5	Bones are fused
Coccyx	3 to 5	Bones are fused

- The *sacrum* is a triangular-shaped bone that consists of five fused vertebrae.
- The *coccyx* (commonly called the tailbone) is a small, triangular-shaped bone made up of three to five fused vertebrae; it is considered nonessential in humans.

► The Rib Cage

LO 23.7

The rib cage is made of 12 pairs of ribs and the **sternum** (see Figure 23-9). The sternum—often called the breastplate—forms the front middle portion of the rib cage. The cartilaginous tip of the sternum is known as the *xiphoid process*. The sternum joins with the clavicles and most ribs. All 12 pairs of ribs are attached posteriorly to thoracic vertebrae. The ribs themselves are classified in three groups based on their anterior attachment:

- **True.** The first seven pairs of ribs are *true ribs*. They attach directly to the sternum through pieces of cartilage called *costal cartilage*.
- **False.** Rib pairs 8, 9, and 10 are called *false ribs*. They do not attach directly to the sternum by individual cartilage but instead attach to the costal cartilage of rib pair number 7.
- **Floating.** Rib pairs 11 and 12 are called *floating ribs* because they do not attach anteriorly to the sternum or to any other structure.

FIGURE 23-8 Vertebral column: (a) lateral view and (b) posterior view.

FIGURE 23-9 Thoracic rib cage showing pectoral girdle attachment of upper extremities.

FIGURE 23-10 (a) The pectoral girdle with upper limb attached. (b) Frontal view of upper limb (palm anterior). (c) Frontal view of upper limb (palm posterior). (d) Posterior view of right elbow.

► Bones of the Shoulders, Arms, and Hands

LO 23.8

The bones of the shoulders make up the pectoral girdle and include the clavicles and the scapulae (see Figure 23-10). They attach the arms to the axial skeleton.

- The **clavicles**, or collar bones, are slender in shape. Each joins with the sternum and a scapula.
- **Scapulae** (or shoulder blades) are thin, triangular-shaped flat bones located on the dorsal surface of the rib cage. Each scapula joins with the head of a humerus and a clavicle.

The upper limb, or arm, bones include the humerus, radius, and ulna:

- The **humerus** is located in the upper part of the arm. Its proximal end joins with the scapula, and its distal end attaches at the radius and the ulna.

- The **radius** is the lateral bone of the forearm. It is on the same side of the arm as your thumb. Proximally, it joins with the humerus and the ulna, and distally with the carpal (wrist) bones.
- The **ulna** is the medial bone of the lower arm. The proximal end of the ulna joins with the humerus to form the elbow joint. Distally, it also joins with the radius and some of the carpal bones of the wrist.

The bones of the hand include carpals, metacarpals, and phalanges:

- **Carpals** are wrist bones. Each wrist contains eight marble-sized carpal bones.
- **Metacarpals** form the palms of the hands. Each hand has five metacarpals.
- **Phalanges** are the bones of the fingers. There are 14 phalanges in each hand—3 for each finger and 2 per thumb.
- The joints between the phalangeal bones are the proximal and distal *interphalangeal* (PIP and DIP) joints.

FIGURE 23-11 (a) Pelvic girdle. (b) Radiograph of the pelvic girdle.

© Sandra Baker/Getty Images

- The joints that join the phalanges to the metacarpals are called the *metacarpophalangeal* (MCP) joints. You probably know these joints as the knuckles.

Refer to Figure 23-10 for the bones of the shoulders, arms, and hands.

► Bones of the Hips, Legs, and Feet

LO 23.9

The hip bones, also called *coxal* bones, attach the legs to the axial skeleton. They also protect pelvic organs. Each coxal bone has three parts: the ilium, the ischium, and the pubis.

- The *ilium* is the most superior part of a coxal bone. When you put your hands on your hips, you are touching the part of the ilium called the *iliac crest*.
- The *ischium* forms the lower part of a coxal bone and the pubis forms the front.
- The *pubis* bones of each coxal bone join together to form the *symphysis pubis*, which is also referred to as the *pelvic girdle* (see Figure 23-11).

The bones of the lower limb, or leg, include the femur, the patella, the tibia, and the fibula.

- The *femur* is the thigh bone and the largest bone in the body. Its proximal end joins with the hip bone at the *acetabulum* (or hip socket). Ligaments and muscles hold it in place.
- The distal end of the femur attaches to the tibia and the **patella** (kneecap). The patella is a sesamoid bone that literally resembles a sesame seed—a small, rounded bone in front of the knee joint.
- The **tibia** (or shinbone) is the medial bone of the lower leg. Its proximal end joins with the femur and fibula, and distally to the ankle bones.

- The **fibula** is the lateral bone of the lower leg. It is much thinner than the tibia. It joins with the ankle bones at its distal end. Figure 23-12 illustrates the bones of the lower extremity.

FIGURE 23-12 (a) Anterior view of the right lower limb. (b) Lateral view of the right knee. (c) Posterior view of the right knee.

The bones of the foot include the tarsals, the metatarsals, and the phalanges.

- The *tarsal* bones form the back of the foot. The *calcaneus*, or heel bone, is the largest tarsal bone. There are seven tarsal bones per foot.
- **Metatarsals** are bones that form the front of the foot. There are five metatarsals per foot.
- The bones of the toes are called *phalanges*. Each foot contains 14—2 for each big toe and 3 in all the other toes. The joints between these lower phalanges are interphalangeal joints, just like those of the fingers.
- The joints that join the toes to the foot are called *metatarsophalangeal* (MTP) joints.

► Joints

LO 23.10

Joints are the junctions between bones. Based on their structure, joints can be classified as fibrous, cartilaginous, or synovial.

- The bones of *fibrous joints* are connected together with short fibers. So the bones of this type of joint do not normally move against each other. Most fibrous joints are found between cranial bones and facial bones. Fibrous joints in the skull are called **sutures**.
- The bones of *cartilaginous joints* are connected together with a disc of cartilage. This type of joint is slightly movable. The joints between vertebrae are cartilaginous joints.
- The bones of *synovial joints* are covered with hyaline cartilage and are held together by a fibrous joint capsule (see

Figure 23-13). The joint capsule is lined with a synovial membrane, which secretes a slippery fluid called *synovial fluid*. This fluid allows the bones to move easily against each other. Bones are also held together through tough, cord-like structures called *ligaments*. Synovial joints are freely movable. Examples of synovial joints are the elbows, knees, shoulders, and knuckles.

FIGURE 23-13 Structure of a synovial joint.

PATHOPHYSIOLOGY

LO 23.11

Common Diseases and Disorders of the Skeletal System

Arthritis is a general term meaning “joint inflammation.” Although there are more than 100 types of arthritis, we will discuss the two most common types: osteoarthritis and rheumatoid arthritis.

OSTEOARTHRITIS, also known as *degenerative joint disease (DJD)*, is the most common type of joint disorder, affecting nearly everyone to some degree by the age of 70. DJD primarily affects the weight-bearing joints of the hips and knees, and the cartilage between the bones and the bones themselves begin to break down.

Causes. Research points to inflammatory processes or metabolic disorders as the etiology of DJD.

Signs and Symptoms. These include joint stiffness, aching, and pain, especially with weather changes. There is often fluid around the joint and grating noises with joint movement.

Treatment. Anti-inflammatory drugs, including aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs) like naproxen and Feldene®, may be used. Intra-articular steroid injections

may be tried for severe cases. In some cases, a series of injections of hyaluronic acid-containing medications is used when other treatments do not work. These injections serve as joint fluid replacement. Some success has been found with transplanting harvested cartilage cells from the patient’s healthy knee cartilage, which are then grown in the lab and reinjected into the patient’s diseased joint. Surgical scraping of the joint may also be done to remove deteriorated bone fragments. As a last resort, joint replacement may be recommended.

Joint replacement prostheses can be metal, plastic, or a combination of both. The physician can surgically replace part of the joint (partial) or the entire joint (total). An example of a partial hip replacement is the Birmingham Hip Resurfacing prosthesis. In this procedure the head of the femur is replaced by an all-metal prosthesis (see Figure 23-14). One of the advantages of partial joint replacement is that it conserves more bone than conventional total joint replacement. Conserving bone is important if additional surgery is needed in the future. The surgeon will have more natural bone to work with if a revision or new prosthesis is required.

FIGURE 23-14 X-ray image of the Birmingham Hip Resurfacing prosthesis of the left hip.

© Total Care Programming, Inc.

RHEUMATOID ARTHRITIS (RA) is the second most common form of arthritis. RA is a chronic, systemic, inflammatory disease that attacks the smaller joints, typically of the hands and feet, as well as the surrounding tissues of those joints. There may be flares or attacks of pain and inflammation followed by periods of remission. RA is three times more common in women than in men.

Causes. RA is believed to be an autoimmune disease, triggering joint inflammation.

Signs and Symptoms. In this disease, the body's immune system attacks the synovial membrane, causing edema (swelling) and congestion. Tissue becomes granular and thick, eventually destroying the joint capsule and bone. Scar tissue forms, bones atrophy, and visible deformities become apparent due to the bone malalignment and immobility. Patients also have moderate to severe pain in the affected joints.

Treatment. Treatment includes anti-inflammatory drugs, exercise, heat or cold treatments, and cortisone injections. Researchers are working with genetic techniques to block the immune system reaction. Low-impact aerobic exercise may be helpful, and some patients find warm water exercises beneficial, too.

BURSITIS is inflammation of a bursa, which is a fluid-filled sac that cushions tendons. It occurs most commonly in the elbow, knee, shoulder, and hip.

Causes. Overuse of and trauma to joints are the most common causes of this condition. Bacterial infections can also cause bursitis.

Signs and Symptoms. These include joint pain and swelling, as well as tenderness in the structures surrounding the joint.

Treatment. The most common treatments are bed rest, pain medications, steroid injections, aspiration of excess fluid from the bursa, and antibiotics.

EWING SARCOMA FAMILY OF TUMORS (ESFT) is a group of tumors that affect different tissue types. However, the tumors primarily affect bone.

Causes. Causes of ESFT are not clear, but it mostly affects Caucasians between the ages of 10 and 20. The tumors are usually located in the lower extremities but may also occur in the pelvis, chest wall, upper extremities, spine, and skull.

Signs and Symptoms. Fever, pain in the tumor location, fractures, and bruises in the tumor location are the primary symptoms.

Treatment. Treatment options include surgery, chemotherapy, radiation therapy, a bone marrow transplant, and stem cell transplant.

FRACTURES are cracks, breaks, or splintering of a bone. Fractures are categorized in several ways (Figure 23-15). Complete fractures go across the entire bone; incomplete fractures go through only part of the bone. Comminuted fractures are those in which the bone has broken into several fragments. In a greenstick fracture, the bone is bent, but only one side is fractured. Greenstick fractures occur most often in children because their bones are still soft and pliable. A fracture is closed if it does not cause a break in the skin. In open fractures, the bone breaks through the skin. A **dislocation** is the displacement of a bone end from the joint.

Causes. Fractures and dislocations are most often caused by falls, automobile accidents, and sports injuries. Fractures may also occur in people with bone disorders such as tumors, osteoporosis, and Paget's disease.

Signs and Symptoms. After an accident or a fall, the patient may have intense pain, localized swelling, bruising, bleeding, a limb or joint that is deformed or out of place, numbness, and loss of use of the limb.

Treatment. Fractures and dislocations must be realigned (put back in place) and immobilized. This is usually accomplished by casting or splinting but may require surgical placement of plates, screws, or pins. For more information about emergency treatment of fractures, refer to the *Emergency Preparedness* chapter.

GOUT, also known as *gouty arthritis*, is a type of arthritis that usually occurs more frequently with age.

Causes. Gout is caused by deposits of uric acid crystals in the joints. People with gout cannot properly break down uric acid and remove it from their bloodstream.

Signs and Symptoms. Symptoms include sudden or chronic joint pain, commonly in the great toe, joint swelling and stiffness, and fever.

Treatment. The most common treatments are pain medications and changes to the patient's diet. Patients should eliminate from their diet certain foods that cause the formation of uric acid (meats, fish, beer, and wine). There are medications available that increase uric acid elimination by the kidneys (uricosuric agents) or decrease uric acid production (xanthine oxidase inhibitors).

FIGURE 23-15 Various types of fractures.

KYPHOSIS is an abnormal curvature of the spine, most often at the thoracic (chest) level. This condition is often referred to as humpback.

Causes. Adolescent kyphosis may result from growth retardation or improper development of the epiphyses as a result of rapid growth. Poor posture may exacerbate or worsen this condition. The adult form of kyphosis is frequently the result of aging and degenerative disc disease of the intervertebral discs and vertebral fracture from underlying osteoporosis.

Signs and Symptoms. In adolescent kyphosis, there may be no symptoms other than visible back curvature. There may be mild pain, tiredness, tenderness, or stiffness of the thoracic spine. In adult kyphosis, the upper back is rounded and there may be pain, back weakness, and fatigue.

Treatment. Childhood kyphosis can be treated with exercise, a firm mattress, and a back brace if needed until growth is completed to keep the spine in alignment. Spinal fusion or grafting may be needed in rare cases of neurological damage or disabling pain. Harrington rods may also be used to keep the vertebrae aligned.

LORDOSIS is an exaggerated inward (convex) curvature of the lumbar spine. Sometimes this condition is called swayback.

Cause. Wearing high heels is a frequent cause. The positioning of the feet with the elevated heel height causes an inward positioning of the back as a counter-balancing measure.

Signs and Symptoms. The main sign is visual inward curvature of the lower back. There may be mild pain with this exaggerated curvature.

Treatment. Avoiding excessive heel height is the best prevention. Once the condition begins, exercise and appropriate footwear will at least keep the condition stable.

OSTEOGENESIS IMPERFECTA (OI) is more commonly called *brittle-bone disease*. People with this disease have decreased amounts of collagen in their bones, which leads to very fragile bones. There are eight types of this disease:

- Type I—the mildest form of OI, which occurs more often than any of the other types
- Type II—the most severe form of OI, normally fatal within a few weeks of birth
- Type III—also a severe type of OI; however, infants usually live longer than those with Type II
- Type IV—a moderate form of OI that is usually diagnosed later in childhood
- Type V—similar to Type IV except that large callouses form around bone fractures. This type accounts for only 5% of OI cases
- Type VI—an extremely rare, moderate form of OI characterized by a defect in mineralization of the bone
- Type VII—a moderate form caused by inheritance of a recessive gene mutation. Similar to Type IV. Moderately abnormal bone growth occurs in this type of OI.
- Type VIII—similar to OI Types II and III, and growth deficiency is severe; however, sclera are white in Type VIII

Cause. The disorder is hereditary.

Signs and Symptoms. These include fractures (all types); blue sclera (types I, II, III, and IV); dental problems (types III and IV); hearing loss (type I); a triangular face (type III); abnormal spinal curves (types I, III, IV, V, and VI); very small stature (types II, III, IV, VII, and VIII); a small chest (types II and III); fractures at birth (types II and III); loose joints (type IV); muscle weakness (types I, III, and IV); and respiratory difficulties (types I, II, III, and VIII).

Treatment. Because this disease has many symptoms, the list of treatments is extensive and includes fracture repair, surgery to strengthen bones by inserting metal rods into them, dental procedures, physical therapy, braces to prevent bone deformities, wheelchairs and other supportive aids, medications, and counseling. Other surgeries may be required to treat lung and heart problems that sometimes occur with this disease.

OSTEOPOROSIS is a condition in which bones become thin (more porous) over time. It is a very common disorder in the United States and affects women more than men and Caucasians more than any other race. This condition occurs because of hypocalcemia in which bone is broken down to release calcium and is not replaced in sufficient amounts; thus, bone density decreases.

Causes. These include hormone deficiencies (estrogen in women and testosterone in men), a sedentary lifestyle, a lack of calcium and vitamin D in the diet, bone cancers, corticosteroid excess (usually as a result of endocrine diseases), smoking, excess alcohol consumption, and steroid use.

Signs and Symptoms. There are usually no symptoms in the early stages of this disease. Patients at high risk, especially

those with a family history of osteoporosis, should request bone densitometry studies to catch the disease before symptoms begin. Patients in later stages of the disease may experience fractures (usually of the spine, wrists, or hips), back and neck pain, a loss of height over time, and an abnormal curving of the spine (kyphosis).

Treatment. The most common treatments include medications to prevent bone loss and relieve bone pain; hormone replacement therapy; lifestyle changes to prevent bone loss (including regular exercise and diets or supplements that include calcium, phosphorus, and vitamin D); moderation in use of alcohol; and stopping smoking.

OSTEOSARCOMA is a type of bone cancer, usually affecting the leg bones, that originates from osteoblasts, the cells that make bony tissue. It occurs most often in children, teens, and young adults and more often in males than females.

Causes. The etiology of this type of cancer is unclear.

Signs and Symptoms. Primary symptoms include pain in affected bones (usually the legs), swelling around affected bones, and an increase in pain with movement of the affected bones.

Treatment. Treatments include surgery, chemotherapy, and radiation therapy. Amputation of the affected limb, followed by a prosthesis fitting, may be needed in some cases to prevent metastasis.

PAGET'S DISEASE causes bones to enlarge and become deformed and weak. It usually affects people over the age of 40.

Causes. This disease may be caused by a virus or various hereditary factors.

Signs and Symptoms. Bone pain, deformed bones, and fractures are common symptoms. Patients may experience headaches and hearing loss if the disease affects skull bones.

Treatment. Treatments include surgery to remodel bones, hip replacements, medications to prevent bone weakening, and physical therapy.

SCOLIOSIS is an abnormal, S-shaped, lateral curvature of the thoracic or lumbar spine.

Causes. This disorder can develop prenatally when vertebrae do not fuse together. It can also result from diseases that cause weakness of the muscles that hold vertebrae together. Other causes of scoliosis are unknown, but they may be genetic.

Signs and Symptoms. A patient with scoliosis usually has a spine that looks bent to one side, with one shoulder or hip appearing to be higher than the other. Patients often experience back pain.

Treatment. Treatment includes different types of back braces, surgery to correct spinal curves, and physical therapy to strengthen the muscles of the back and abdomen.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
23.1 Describe the structure of bone tissue.	Bones consist of the following substances: osteons (the Haversian system), bone matrix between osteocytes (bone cells), collagen fibers and proteins, lamellae, and canaliculi. Long bones include the femur and humerus; short bones include the carpals and tarsals; flat bones include the ribs and the frontal bone; irregular bones include the vertebrae and bones of the pelvic girdle. The diaphysis is the shaft of the long bone. The epiphysis is an end of a long bone. Articular cartilage covers the end of the long bones. The endosteum lines the medullary cavity. The periosteum is the membrane surrounding the diaphysis.
23.2 Explain the functions of bones.	Bone functions include giving shape to body parts, protecting soft structures of the body, and assisting in movement. The red bone marrow is responsible for hematopoiesis. Bones also store calcium.
23.3 Compare intramembranous and endochondral ossification.	Bones grow through two types of ossification: intramembranous ossification and endochondral ossification. The cartilage plate between the diaphysis and the epiphysis allows for growth of the long bone.
23.4 Describe the skeletal structures and one location of each structure.	Skeletal structures include the following: condyles, crests, epicondyles, foramina, fossae, heads, processes, sutures, trochanters, tubercles, and tuberosities.
23.5 Locate the bones of the skull.	The major bones of the skull are the frontal, parietal, temporal, and occipital bones. The fontanelles are the membranous structures that connect the incompletely developed cranial bones. Within the skull are the mastoid processes, sphenoid, ethmoid, and ear ossicles. The facial bones include the mandible, maxillae, zygomatics, nasal and palatine bones, and vomer. Locations are shown in Figures 23-6 and 23-7.
23.6 Locate the bones of the spinal column.	The spinal column includes cervical, thoracic, and lumbar vertebrae; the sacrum; and the coccyx. Locations are shown in Figure 23-8.
23.7 Locate the bones of the rib cage.	There are 12 pairs of ribs, a sternum, and the xiphoid process. Locations are shown in Figure 23-8.
23.8 Locate the bones of the shoulders, arms, and hands.	Each upper extremity includes the clavicle, scapula, humerus, radius, ulna, carpals, metacarpals, and phalanges. Locations are shown in Figure 23-10.
23.9 Locate the bones of the hips, legs, and feet.	The bones of the hip, leg, and foot include the coxal bones, the femur, patella, tibia, fibula, metatarsals, tarsals, and phalanges. Locations are shown in Figures 23-11 and 23-12.
23.10 Describe the three major types of joints and give examples of each.	The three joint types are fibrous joints (for example, sutures of the skull), cartilaginous joints (for example, the joints between vertebrae), and synovial joints (for example, the elbow). A synovial joint consists of hyaline-covered bones held together by a fibrous joint capsule, which is lined by a synovial membrane that secretes synovial fluid. Ligaments hold the bones of these joints together.

LEARNING OUTCOMES

23.11 Describe the common diseases and disorders of the skeletal system.

KEY POINTS

There are many common diseases and disorders of the bones and the skeletal system with varied signs, symptoms, and treatments. Examples include arthritis, bursitis, EFT, fractures, gout, kyphosis, lordosis, and scoliosis, as well as osteoporosis and osteosarcoma.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall John Miller from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. Explain to John what bursitis is and what causes it.
2. What treatment might the family nurse practitioner prescribe for John's bursitis?
3. Why do you think John's family nurse practitioner suspects bursitis and not a fracture?
4. John's family nurse practitioner thinks that John may have bruised the sesamoid bone in front of his knee joint. What is the medical term for this bone?
5. The X-ray findings state that AP and lateral views of the knee and elbow showed no fractures. Describe the terms *AP* and *lateral*.

EXAM PREPARATION QUESTIONS

1. (LO 23.1) The tiny canals of cancellous bone that allow for the spread of nutrients are called
 - a. Lamellae
 - b. Lacunae
 - c. Osteons
 - d. Canaliculi
 - e. Osteoblasts
2. (LO 23.3) Which substance is necessary for bone to absorb calcium?
 - a. Vitamin C
 - b. Phosphorus
 - c. Vitamin D
 - d. Protein
 - e. Carbohydrates
3. (LO 23.4) Articulation is another name for a
 - a. Fossa
 - b. Joint
 - c. Foramen
 - d. Suture
 - e. Tubercle
4. (LO 23.5) Neck muscles attach to the skull via the _____ process.
 - a. Mastoid
 - b. Xiphoid
 - c. Styloid
 - d. Zygomatic
 - e. Coracoid
5. (LO 23.9) The acetabulum is the
 - a. Hip bone
 - b. Knee joint
 - c. Hip socket
 - d. Shoulder bone
 - e. Shoulder socket
6. (LO 23.11) A lateral curvature of the spine is known as
 - a. Lordosis
 - b. Kyphosis
 - c. Osteoporosis
 - d. Scoliosis
 - e. Sarcoma
7. (LO 23.11) The medical term for brittle-bone disease is
 - a. Ewing sarcoma family of tumors
 - b. Osteogenesis imperfecta
 - c. Rheumatoid arthritis
 - d. Osteoporosis
 - e. Paget's disease
8. (LO 23.1) Which of the following is the shaft of a long bone?
 - a. Spine
 - b. Epiphysis
 - c. Crest
 - d. Periosteum
 - e. Diaphysis

9. (LO 23.1) The bones of the rib cage are

- a. Long bones
- b. Flat bones
- c. Irregular bones
- d. Short bones
- e. Sesamoid bones

10. (LO 23.4) Which of the following is an interlocking line of union between bones?

- a. Suture
- b. Condyle
- c. Process
- d. Articulation
- e. Fossa

M E D I C A L T E R M I N O L O G Y P R A C T I C E

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **mast/oid** = mast means “breast” + oid means “resembling”

MASTOID means “resembling a breast.” (A mastoid process resembles a breast.)

The Muscular System

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Ken Washington	12/1/19XX	Sulfa
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	891-12-743	AFO brace ordered

Ken F. Washington, a 61-year-old male patient, has arrived for a follow-up visit from a recent hospitalization for a stroke. Until this hospitalization, he had no major health issues. However, he now has weakness in his left arm and his speech is difficult to understand. He has left-leg weakness with foot drop, a condition characterized by an inability to raise the front part of the foot. The foot drop is causing

© McGraw-Hill Education

him to trip when he walks more than a few steps. The physician has ordered a physical therapy evaluation and treatment as needed. The patient has been placed on an exercise regimen for his left-arm weakness. A special ankle foot orthosis (AFO) brace has been ordered to help Ken with his foot drop.

Keep Ken in mind as you study this chapter.

There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 24, you will be able to:

- 24.1** Describe the functions of muscle.
- 24.2** Compare the three types of muscle tissue, including their locations and characteristics.
- 24.3** Explain how muscle tissue generates energy.
- 24.4** Describe the structure of a skeletal muscle.
- 24.5** Differentiate between the terms *origin* and *insertion*.
- 24.6** Identify the major skeletal muscles of the body, giving the action of each.
- 24.7** Summarize the changes that occur to the muscular system as a person ages.
- 24.8** Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the muscular system.

KEY TERMS

acetylcholine	myofibrils
acetylcholinesterase	origin
agonist	prime mover
antagonist	sarcolemma
aponeurosis	sarcoplasm
creatine phosphate	sarcoplasmic reticulum
fascicle	sphincter
insertion	striations
lactic acid	synergist
multi-unit smooth muscle	visceral smooth muscle

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.6** Compare structure and function of the human body across the life span
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms, and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- a. Define and use entire basic structure of medical words and be able to accurately identify in the correct context, i.e. root, prefix, suffix, combinations, spelling, and definitions
- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty

► Introduction

Your bones and joints do not produce movement all by themselves. Instead, your muscles—by alternating between contraction and relaxation—cause your bones and supported structures to move. The human body has more than 600 individual muscles. Although each muscle is a distinct structure, muscles act in groups to perform particular movements. In this chapter, you will explore the differences among three muscle tissue types, the structure of skeletal muscles, muscle actions, and the names of skeletal muscles.

► Functions of Muscle

LO 24.1

Muscle tissue is unique because it has the ability to contract. This contraction allows muscles to perform various functions. In addition to allowing the human body to move, muscles provide stability, control body openings and passages, and warm the body.

Movement

Skeletal muscles are attached to bones by tendons. Because skeletal muscles cross joints, when these muscles contract, the bones they attach to move. This allows for various body motions, like walking or waving your hand. Facial muscles are attached to the skin of the face; when they contract, different facial expressions are produced, such as smiling or frowning. Smooth muscle is found in the walls of various organs, like the stomach, intestines, and uterus. The contraction of smooth muscle in these organs produces the movement of their contents, such as the movement of food material through the intestine or the birth of a child being pushed from the mother's uterus. Cardiac muscle of the heart produces the atrial and ventricular contractions that pump blood into the blood vessels.

Go to CONNECT to see an animation exercise about *Muscle Contraction*.

Stability

You rarely think about it, but muscles are holding your bones tightly together so that your joints remain stable. There are also very small muscles holding your vertebrae together to stabilize your spinal column.

Heat Production

When muscles contract, heat is released, which helps the body maintain a normal temperature. This is why moving your body—say, jogging in place for a few seconds—can make you warmer if you are cold.

Control of Body Openings and Passages

In addition to providing important structural support for your bones and joints, muscles also form valve-like structures called **sphincters** around various body openings and passages. These sphincters control the movement of substances into and out of these passages. For example, a urethral sphincter prevents urination until you relax it to permit urination.

► Muscle Cells and Tissue

LO 24.2

There are three types of muscle tissue: skeletal, smooth, and cardiac. Muscle tissue is made of muscle cells. Muscle cells, or *myocytes*, are called muscle fibers because of their long lengths. The cell membrane of a muscle fiber

Muscle Group	Major Location	Major Function	Striated (Yes/No)	Mode of Control	Rate of Contraction	Intercalated Discs
Skeletal muscle	Attached to bones and the skin of the face	Produces body movements and facial expressions	Yes	Voluntary	Fast to contract and relax	No
Smooth muscle	Walls of hollow organs, blood vessels, and iris	Moves contents through organs; vasoconstriction	No	Involuntary	Slow to contract and relax	No
Cardiac muscle	Wall of the heart	Pumps blood through heart	Yes	Involuntary	Groups of muscle fibers contract as a unit	Yes

is called a **sarcolemma**. The cytoplasm of this cell type is called **sarcoplasm**, and the endoplasmic reticulum is called **sarcoplasmic reticulum**. Most of the sarcoplasm is filled with long structures called **myofibrils**. It is the arrangement of the actin and myosin filaments in myofibrils that produces the **striations**, or stripes, observed in skeletal and cardiac muscle cells. Muscle fibers are controlled by motor neurons that release chemical substances called *neurotransmitters*, such as acetylcholine, dopamine, and epinephrine, onto the fibers. See Figure 24-1 for an illustration of the structure of a skeletal muscle. Study Table 24-1 to review the locations and features of the three types of muscle tissue.

Skeletal Muscle

Skeletal muscle fibers respond only to the neurotransmitter **acetylcholine**, which causes skeletal muscle to contract. Once contraction has occurred, skeletal muscles release an enzyme called **acetylcholinesterase**, which breaks down acetylcholine. This allows the muscle to relax. Figure 24-2a shows a photomicrograph of skeletal muscle. These muscles are responsible for body movement, posture, and heat generation through shivering.

Smooth Muscle

There are two types of smooth muscle: multi-unit and visceral. **Multi-unit smooth muscle** is found in the iris of the

FIGURE 24-1 Structure of a skeletal muscle.

eye and the walls of blood vessels. This muscle type contracts in response to neurotransmitters and hormones. **Visceral smooth muscle** contains sheets of muscle cells that closely contact each other. It is found in the walls of hollow organs like the stomach, intestines, bladder, and uterus. Muscle fibers in visceral smooth muscle respond to neurotransmitters, but they also stimulate each other to contract, so the muscle fibers tend to contract and relax together. This type of muscle produces an action called peristalsis. *Peristalsis* is a rhythmic contraction that pushes substances through tubes of the body. For example, peristalsis in the lower two-thirds of the esophagus moves the *bolus* of food through the stomach; peristaltic muscle movements in the fallopian tubes propel the ovum (egg) through the tubes toward the uterus.

Two neurotransmitters are involved in smooth muscle contraction—acetylcholine and norepinephrine. Depending on the smooth muscle type, these neurotransmitters cause or inhibit contractions. Figure 24-2b is a photomicrograph of smooth muscle.

Cardiac Muscle

Groups of cardiac muscle are connected to each other through *intercalated discs*—discs with tunnels that physically connect the cardiac muscle cells. These discs allow the fibers in each group to contract and relax together—a design that allows the heart to work as a pump. First, the atria (holding chambers) contract and relax together; then the ventricles (pumping chambers) contract to send blood to the lungs and body, after which they relax and the cycle starts again. Cardiac muscle is also self-exciting, which means that it does not need nerve stimulation to contract. Nerves only speed up or slow down the contraction of the heart. Like smooth muscle, cardiac muscle responds to two neurotransmitters—acetylcholine and norepinephrine. Acetylcholine slows the heart rate, and norepinephrine speeds it up. Figure 24-2c is a photomicrograph of cardiac muscle.

► Production of Energy for Muscle LO 24.3

Because a lot of adenosine triphosphate (ATP)—a type of chemical energy—is needed for sustained or repeated muscle contractions, a muscle cell must have multiple ways to store or make this substance. Muscle cells make this energy in three ways:

- **Creatine phosphate** production. Creatine phosphate production is a rapid way for a muscle to produce energy. When ATP is used during muscle contraction, it loses a phosphate and, therefore, energy. Imagine a desk toy that has five ball bearings suspended by strings. You create potential energy by lifting one of the ball bearings away from the others. When you release the ball bearing—breaking the bond between your fingers and the ball—the potential energy is released and the ball bearing hits the others, causing them to swing back and forth for several minutes. As with the ball bearing, energy stored in the phosphate bond is released when the bond is broken. Creatine phosphate “donates” a phosphate group, restoring energy potential.
- **Aerobic respiration**—an energy-forming biochemical process that requires oxygen—uses the body’s store of glucose to

(a)

(b)

(c)

FIGURE 24-2 Photomicrographs of (a) skeletal, (b) smooth, and (c) cardiac muscle.

© McGraw-Hill Education/AI Telser, photographer

make ATP. A cell breaks down glucose into pyruvic acid using oxygen (hence the term *aerobic*). The pyruvic acid is further converted into acetyl coenzyme A, which begins a series of reactions known as the *Krebs cycle*, or citric acid cycle. The oxygen needed for this method is stored in the muscle pigment called *myoglobin*, which also gives muscle its pinkish color.

- **Lactic acid** production occurs when a cell is low in oxygen and must convert pyruvic acid to lactic acid. This conversion produces a small amount of ATP for the cell, but because lactic acid is a waste product, it must then be released from the cell.

Oxygen Debt

Oxygen debt occurs when skeletal muscle is used strenuously for several minutes. When pyruvic acid is converted to lactic acid for energy production, the lactic acid builds up and causes muscle fatigue and soreness. The lactic acid is taken to the liver via the bloodstream to be converted back into glucose, which requires more energy. The amount of oxygen the liver cells need to make enough ATP for this conversion results in the oxygen debt. This process explains why your body still burns energy even after you are done exercising.

Muscle Fatigue

Muscle fatigue is a condition in which a muscle has lost its ability to contract. It usually develops because of an accumulation of lactic acid. It can also occur if the blood supply to a muscle is interrupted or if a motor neuron loses its ability to release acetylcholine onto muscle fibers. Cramps—painful, involuntary contractions of muscles—can accompany muscle fatigue. For this reason, if you have just finished an intense workout, it is important to replenish your electrolytes by drinking fluids and eating foods that are good sources of sodium, potassium, and calcium.

Structure of Skeletal Muscles LO 24.4

Skeletal muscles are the major organs that make up the muscular system. A skeletal muscle consists of connective tissue, skeletal muscle tissue, blood vessels, and nerves. When you see marbling in a steak, you are actually viewing connective tissue. The red portion of the steak is the muscle tissue.

The following connective tissue coverings are associated with skeletal muscles (see Figure 24-1):

- **Fascia.** Connective tissue located just below the skin that helps support and hold together muscles, bones, nerves, and blood vessels.
- **Tendon.** Tough, cord-like structure made of fibrous connective tissue that connects muscles to bones.
- **Aponeurosis.** Tough, sheet-like structure made of fibrous connective tissue. It typically attaches muscles to other muscles.
- **Epimysium.** A thin covering that is just deep to the fascia of a muscle. It surrounds the entire muscle.
- **Perimysium.** A sheath of connective tissue surrounding a group of 10 to 100 muscle fibers. This grouping of muscle fibers is called a **fascicle**.
- **Endomysium.** The connective tissue that surrounds individual muscle cells.

Attachments and Actions of Skeletal Muscles LO 24.5

In order for skeletal muscle to produce movement, it must cross a joint and have at least two attachments to bone—one to the bone proximal to the joint and the second distal to the joint. Typically, one of the bones is more movable than the other when the muscle contracts. These attachments are known as the *origin* and *insertion*. An **origin** is an attachment site for the less movable bone during muscle contraction. An **insertion** is an attachment site for the more movable bone during muscle contraction. For example, the biceps brachii (the muscle on the anterior upper arm) attaches to two places on the scapula and to one site on the radius. When the biceps brachii contracts, the radius moves and the arm bends at the elbow. So the origin of the biceps brachii is where it attaches to the scapula. The insertion site of the biceps brachii is its attachment site on the radius (see Figure 24-3).

Most of the time, body movement is not produced by only one muscle, but by a group of muscles. However, one muscle is responsible for most of the movement; this muscle is called the **prime mover** or **agonist**. Other muscles help the prime mover by stabilizing joints; these muscles are called **synergists**. An **antagonist** is a muscle that produces a movement opposite to the prime mover. When the prime mover contracts, the antagonist must relax in order to produce a smooth body movement. For example, when you bend your arm at the elbow, the prime mover (agonist) is the biceps brachii. The synergist muscles are the brachialis and brachioradialis. The antagonist is the triceps brachii because its action is to extend the arm at the elbow. While the prime mover and synergists contract, the agonist relaxes; when the antagonist contracts, the prime mover and synergists relax.

FIGURE 24-3 Origins and insertion of biceps brachii.

The body movements produced by skeletal muscles include the following:

- *Flexion*—bending a body part or decreasing the angle of a joint
- *Extension*—straightening a body part or increasing the angle of a joint
- *Hyperextension*—extending a body part past the normal anatomical position
- *Dorsiflexion*—pointing the toes up
- *Plantar flexion*—pointing the toes down
- *Abduction*—moving a body part away from the midline of the body
- *Adduction*—moving a body part toward the midline of the body
- *Rotation*—twisting a body part—for example, turning your head from side to side
- *Circumduction*—moving a body part in a circle—for example, moving your arm in a circular motion
- *Pronation*—turning the palm of the hand down or lying face down
- *Supination*—turning the palm of the hand up or lying face up
- *Inversion*—turning the sole of the foot medially
- *Eversion*—turning the sole of the foot laterally
- *Retraction*—moving a body part posteriorly
- *Protraction*—moving a body part anteriorly

- *Elevation*—lifting a body part—for example, elevating your shoulders as in a shrugging gesture
- *Depression*—lowering a body part—for example, lowering your shoulders

See Figures 24-4, 24-5, and 24-6 for illustrations of these types of movements. As a medical assistant, it is important to understand these movements so that you can assist with judging and measuring your patients' ability to perform range-of-motion (ROM) exercises when assessing injuries and illnesses.

Major Skeletal Muscles

LO 24.6

The name of a skeletal muscle often describes it in some way. Usually, the name indicates the location, size, action, shape, or number of attachments of the muscle. For example, the pectoralis major is named for its large size (major) and its location (pectoral, or chest, region). The sternocleidomastoid is named for its attachment sites—*sterno* (sternum), *cleido* (clavicle), and *mastoid* (the mastoid process of the temporal bone, located behind the ear). As you study muscles, you will find it easier to remember them if you think about what the name describes. Figures 24-7 and 24-8 show the anterior and posterior views of superficial skeletal muscles.

Muscles of the Head

The muscles of the head include those that move the head, provide facial expression, and move the jaw. Muscles that

FIGURE 24-4 Adduction, abduction, dorsiflexion, plantar flexion, hyperextension, extension, and flexion.

FIGURE 24-5 Rotation, circumduction, supination, and pronation.

FIGURE 24-6 Eversion, inversion, protraction, retraction, elevation, and depression.

move the head include the following, and hints to assist you with remembering the locations for some of these muscles are provided in parentheses:

- Sternocleidomastoid. This muscle pulls the head to one side and pulls the head to the chest. (sterno = sternum, cleido = clavicle, mastoid = mastoid)

- Splenius capitis. This muscle rotates the head and allows it to bend to the side. (capit = head)

Muscles of facial expression include the following:

- Frontalis. This muscle raises the eyebrows. (frontal = pertaining to the front)

FIGURE 24-7 Anterior view of superficial skeletal muscles.

FIGURE 24-8 Posterior view of superficial skeletal muscles.

- Orbicularis oris. This muscle allows the lips to pucker. (oris = oro or mouth)
- Orbicularis oculi. This muscle allows the eyes to close. (oculi = eye)
- Zygomaticus. This muscle pulls the corners of the mouth up. (zygomat = cheekbone)
- Platysma. This muscle pulls the corners of the mouth down.

The muscles of the jaw allow for mastication (chewing) and include the following:

- Masseter and temporalis. These muscles close the jaw. (masseter as in mastication or chewing, temporo = temple)

- Internal and external pterygoids. These muscles help position the jaw.
- Sternohyomastoid. This muscle opens the jaw. (hyo = hyoid bone)

Arm Muscles

Muscles that move the arm include muscles of the arm and forearm (see Figures 24-7, 24-8, and 24-9). These muscles include

- Pectoralis major. This muscle pulls the arm across the chest; it also rotates and adducts the arms. (pectoro = chest)

(a)

(b)

FIGURE 24-9 Muscles of the (a) anterior hand and (b) posterior forearm.

- **Latissimus dorsi.** This muscle acts to extend, adduct, and rotate the arm inwardly. (latissimus = butterfly, dorsi = back)
- **Deltoid.** This muscle acts to abduct and extend the arm at the shoulder.
- **Subscapularis.** This muscle rotates the arm medially. (sub = below, scapulo = shoulder blade)
- **Infraspinatus.** This muscle rotates the arm laterally. (infra = below, spinat = spine)

Muscles that move the forearm include the following:

- **Biceps brachii.** This muscle flexes the arm at the elbow and rotates the hand laterally. (bi = two, ceps = insertion, brachii = arm)
- **Brachialis.** This muscle flexes the arm at the elbow. (brachii = arm)
- **Brachioradialis.** This muscle flexes the forearm at the elbow. (brachii = arm, radio = radius)
- **Triceps brachii.** This muscle extends the arm at the elbow. (tri = three, ceps = insertion, brachii = arm)
- **Supinator.** This muscle rotates the forearm laterally (supination). (supine = palm up)
- **Pronator teres.** This muscle rotates the forearm medially (pronation). (prone = palm down)

Muscles of the Wrist, Hand, and Fingers

Muscles that move the wrist, hand, and fingers can be seen in Figures 24-7, 24-8, and 24-9. These muscles include the following:

- **Flexor carpi radialis and flexor carpi ulnaris.** These muscles flex and abduct the wrist. (radio = radius, ulna = ulna)
- **Palmaris longus.** This muscle flexes the wrist.
- **Flexor digitorum profundus.** This muscle flexes the distal joints of the fingers but not the thumb. (digits = fingers)
- **Extensor carpi radialis longus and brevis.** These muscles extend the wrist and abduct the hand. (carpo = wrist, radio = radius, long = long, brev = brief or short)
- **Extensor carpi ulnaris.** This muscle extends the wrist. (carpo = wrist, ulna = ulna)
- **Extensor digitorum.** This muscle extends the fingers but not the thumb. (digit = finger)

Respiratory Muscles

The muscles of respiration—breathing—include the following:

- **Diaphragm.** This muscle separates the thoracic cavity from the abdominal cavity; its contraction causes inspiration—breathing in.
- **External and internal intercostals.** The contractions of these muscles expand and then lower the ribs during breathing. See Figure 24-10 on the next page for an illustration of the internal intercostal muscle. (inter = between, costo = rib)

Abdominal Muscles

The muscles of the abdominal wall include the following:

- **External and internal obliques.** These muscles compress the abdominal wall. (oblique = diagonal)
- **Transverse abdominis.** This muscle also compresses the abdominal wall. (transverse = across)
- **Rectus abdominis.** This muscle acts to flex the vertebral column and compress the abdominal wall. (rectus = erect)

See Figures 24-7, 24-8, and 24-10 for illustrations of these muscles.

Muscles of the Pectoral Girdle

The muscles that move the pectoral girdle (shoulder) include the following:

- **Trapezius.** This muscle raises the arms and pulls the shoulders downward. (trapezius = trapezoid)
- **Pectoralis minor.** This muscle pulls the scapula downward and raises the ribs. (pectoro = chest, minor = smaller)

See Figures 24-7, 24-8, and 24-10 for illustrations of these muscles.

Leg Muscles

The leg muscles include muscles of the thigh and lower leg (see Figures 24-7 and 24-8). Muscles that move the thigh include the following:

- **Iliopsoas major.** This muscle flexes the thigh.
- **Gluteus maximus.** This muscle extends the thigh.
- **Gluteus medius and minimus.** These muscles abduct the thighs and rotate them medially.
- **Adductor longus and magnus.** These muscles adduct the thighs and rotate them laterally. (adduct = toward the midline)
- **Biceps femoris, semitendinosus, and semimembranosus.** These three muscles are known as the *hamstring group*. They act to flex the leg at the knee and extend the leg at the thigh.
- **Rectus femoris, vastus lateralis, vastus medialis, and vastus intermedius.** These four muscles are known as the *quadriceps group*; they act to extend the leg at the knee.
- **Sartorius.** This muscle flexes the leg at the knee and thigh. It also abducts the thigh, rotating the thigh laterally but rotating the lower leg medially; it carries out the act of sitting cross-legged.

Muscles of the Ankle, Foot, and Toes

Muscles that move the ankle, foot, and toes include the following:

- **Tibialis anterior.** This muscle inverts the foot and points the foot up (dorsiflexion).
- **Extensor digitorum longus.** This muscle extends the toes and points the foot up.

FIGURE 24-10 Muscles of the anterior chest and abdominal wall.

CAUTION: HANDLE WITH CARE

Muscle Strains and Sprains

Strains are injuries that excessively stretch muscles or tendons. Sprains are more serious injuries that consist of tears to tendons, ligaments, and/or the cartilage of joints. You can teach patients to prevent these types of injuries by doing the following:

- **Warm up.** Warming up muscles for just a few minutes before an intense activity raises muscle temperature. This increase in temperature prevents injuries by making muscle tissue more pliable.
- **Stretch.** Stretching improves muscle performance and should always be done after the warm up or after exercising. A person should never stretch further than he can hold for 10 seconds.
- **Cool down.** Slowing down the exercise before completely stopping prevents dizziness and fainting. If a person suddenly stops exercising, blood can pool in the legs and is prevented from reaching the brain. Cooling down also helps to remove lactic acid from muscles.

If sprains or strains do occur, immediate RICE treatment is recommended:

- **R** is for rest. Resting minimizes bleeding, further injury, and swelling. Sometimes a splint, sling, or crutches may be needed.
- **I** is for ice. Ice minimizes swelling and pain. A bag filled with crushed ice conforms better to a body part than one filled with ice cubes. A bag full of frozen peas or other small vegetables can also be used. The ice should be applied for 10 minutes and then removed for 10 minutes. This should be kept up for about an hour and repeated several times during a 48-hour period.
- **C** is for compression, which minimizes swelling. A bandage should be loosely wrapped around the injured area and the bag of ice. Compression should be applied and removed along with the ice.
- **E** is for elevation. The injured muscle should be elevated, which minimizes swelling, and elevation should be continued as long as swelling is present.

If the patient does not think his symptoms have improved in several days to a week, a physician should be contacted to rule out a more serious injury, such as a torn ligament or muscle, or even a bone fracture.

- **Gastrocnemius.** This muscle flexes the foot and flexes the leg at the knee. It is more commonly referred to as the calf muscle.
- **Soleus.** This muscle also flexes the foot.
- **Flexor digitorum longus.** This muscle flexes the foot and toes.

See Figures 24-7 and 24-8 for illustrations of these muscles.

► Aging and the Musculoskeletal System

LO 24.7

Although the aging of the skeletal system causes more obvious difficulties for patients with diseases and conditions like arthritis, fractures, and osteoporosis, muscular decline often goes hand-in-hand with these changes. Aging causes a decline in the speed

and strength of muscle contractions, even though the actual endurance of muscle fibers changes very little. Elderly patients often have increasing difficulty with dexterity and gripping ability. Mobility may decrease related to the combined decline of the musculoskeletal system. The patient's diet and exercise history, as well as family history, also has a direct impact on the patient's mobility and activity level as he or she ages.

Assistive devices like railings, tub and shower seats, and gripping devices can assist patients who are experiencing difficulties. Exercise routines, particularly pool exercises like swimming and physical therapy, are often helpful in maintaining strength and mobility. Guarding against sprains and strains during exercise routines is essential. See the *Caution: Handle with Care* Muscle Sprains and Strains for more information.

PATHOPHYSIOLOGY

LO 24.8

Common Diseases and Disorders of the Muscular System

BOTULISM is usually thought of as a disease that affects the gastrointestinal tract, but it can also affect various muscle groups. This disease most commonly affects infants. Although a person can survive this disease, its effects may be long-lasting.

Causes. This is a rare but serious disorder caused by the bacterium *Clostridium botulinum*, which normally lives in soil and water. If this bacterium gets on food, it produces a toxin that can lead to a type of food poisoning. The foods most likely to contain *Clostridium botulinum* are canned vegetables, cured pork, raw fish, honey, and corn syrup. A person can also acquire this bacterium through improperly cleaned open wounds.

Signs and Symptoms. This disease causes many symptoms, including dysphagia (difficulty swallowing), paralysis, muscle weakness, nausea and vomiting, abdominal cramps, double vision, dyspnea (difficulty breathing), poor feeding and suckling in infants, the inability to urinate, the absence of reflexes, and constipation. The signs and symptoms usually appear 8 to 40 hours after the toxin is ingested. The diagnosis is usually made by either a blood test to identify the toxin or an analysis of the suspected food. See Figure 24-11.

Treatment. Treatment includes emergency hospitalization, intubation—inserting a tube into the upper airway to open airways, mechanical ventilation if respiratory muscles are impaired, intravenous fluids or nasogastric (through nose to stomach) feeding if swallowing is impaired, and the administration of an antitoxin.

Prevention Tips. You can instruct patients to prevent botulism by observing the following guidelines:

- Never give honey or corn syrup to infants.
- Sterilize home-canned food containers properly (240°F for 35 minutes).
- Do not use foods from bent or bulging cans.
- Never eat foods that smell as if they may have spoiled.
- Cook and store foods properly.

FIGURE 24-11 An infant with paralysis caused by botulism. CDC

FIBROMYALGIA is a fairly common condition that results in chronic pain, primarily in joints, muscles, and tendons. It most ordinarily affects women between the ages of 20 and 50.

Causes. The causes of this disorder are poorly understood. Fibromyalgia may be caused or exacerbated by sleep disturbance, emotional distress, decreased blood flow to muscles, a virus, or any combination of these factors.

Signs and Symptoms. Symptoms include fatigue, tenderness in different areas of the body, sleep disturbances, and chronic facial pain. The diagnosis is usually made by ruling out other possible diseases. It is not normally diagnosed unless a person has muscle and joint pain for at least 3 months in certain body areas.

Treatment. Treatment is varied and includes antidepressants, anti-inflammatory and nerve pain medications, physical therapy, lifestyle changes to reduce stress, counseling to improve coping

skills, reduction or elimination of caffeine to improve sleeping, and dietary supplements to improve nutrition.

MUSCULAR DYSTROPHY (MD) is a group of inherited disorders characterized by muscle weakness and a loss of muscle tissue. There are at least seven types of muscular dystrophy, and they are distinguished from each other by types of symptoms, the age at when symptoms appear, and the cause.

Causes. The causes of this disorder are primarily hereditary. Genetic fetal testing is available.

Signs and Symptoms. The signs and symptoms vary widely and depend on the type of muscular dystrophy. The symptoms of Duchenne muscular dystrophy—the most common and widely known type—progress steadily and are eventually fatal. Other types cause mild symptoms, and patients usually have normal life expectancies. Specific signs and symptoms include muscle weakness in various muscle groups, depending on the type of dystrophy; difficulty walking; drooling; a delayed development of motor skills; frequent falls; intellectual disability in some types; a curved spine; the formation of a claw hand or clubfoot; a loss of muscle mass; the accumulation of fat or fibrous connective tissue in muscles; and arrhythmias (irregular heart rhythms) in some types. The progression of the muscular weakness may also include eventual paralysis of the affected muscle groups. The diagnosis is primarily made through a muscle biopsy. Other tests include deoxyribonucleic acid (DNA) testing; an electromyography (EMG) test, which tests muscle weakness; or an electrocardiogram (ECG), which tests cardiac function.

Treatment. Treatment includes physical therapy to maintain muscle function, the use of braces and wheelchairs, various medications based on the type of MD, and spinal surgery.

MYASTHENIA GRAVIS is a condition in which affected people experience muscle weakness. In this autoimmune condition, a person produces antibodies that prevent muscles from receiving neurotransmitters from neurons. It most commonly affects young women and older men, especially if they have other autoimmune disorders.

Causes. This disease is usually considered an autoimmune disorder.

Signs and Symptoms. The signs and symptoms usually get better with rest and worsen with activity. They include double vision; muscle weakness; dysphagia (difficulty swallowing); difficulty talking, chewing, lifting, or walking; fatigue; drooling; and difficulty breathing. The diagnosis may be difficult, but a single-fiber EMG test is often useful. This test measures the response of a muscle fiber to nervous stimulation. Other tests include acetylcholine receptor antibody tests and the edrophonium test. In a positive edrophonium test, muscle activity increases after medication is given that blocks the breakdown of acetylcholine.

Treatment. Treatments include lifestyle changes to avoid excessive stress, adequate rest, the use of an eye patch to treat double vision, medications to improve communication between nerves and muscles, medications to suppress the immune system, plasmapheresis to remove harmful antibodies from blood, and removal of the thymus.

RHABDOMYOLYSIS is a condition in which the kidneys have been damaged in relation to serious muscle injuries.

Causes. Kidneys become damaged because of toxins released from muscle cells. When muscles are damaged, excessive amounts of the pigment myoglobin are released, which is then broken down into harmful chemicals. Muscles are most often damaged through trauma; excessive use (for example, marathon running); overdoses of cocaine, heroin, and other drugs; alcoholism; and a blockage of the blood supply to the muscles.

Signs and Symptoms. Symptoms include dark urine, muscle tenderness, muscle weakness, muscle stiffness, seizures, joint pain, and fatigue. Diagnosis includes urinalysis for the presence of myoglobin, creatine phosphokinase (CPK), and creatinine; blood is also tested for the presence of myoglobin, CPK, or high levels of potassium. CPK is an enzyme released into the blood when muscles are damaged. Creatinine is a protein released by the breakdown of muscle tissue.

Treatment. Treatment includes hydration to rapidly eliminate toxins from the kidneys, diuretics to help flush toxins from the body, medications to flush excess potassium from the body, and therapy for kidney failure.

TENDONITIS is described as the painful inflammation of a tendon as well as of the tendon-muscle attachment to a bone. The most common locations for tendonitis are the shoulder, hip, heel, and hamstrings. Tendonitis may also be associated with bursitis, the inflammation of the bursa located in synovial joints like the shoulder, elbow, and knee.

Causes. Tendonitis usually occurs after a sports-related activity that results in injury to the tendon-muscle or tendon-to-bone attachment. Other musculoskeletal disorders may also cause or exacerbate this condition.

Signs and Symptoms. These include pain at the joint or muscle attachment that results in limited range of motion (ROM) of the affected area.

Treatment. For the initial injury, using ice for the first 12 to 24 hours will minimize inflammation. After this initial time period, applying heat will help with joint and muscle pain. If calcium deposits are found in the tendon, which can be confirmed by X-ray, heat will aggravate the condition, whereas continued use of ice packs will help to relieve the discomfort. Resting the affected area and taking oral analgesics will also help control pain and reduce inflammation.

TETANUS is commonly called lockjaw. This disease has a high mortality rate, especially in infants. Immediate treatment is necessary to prevent death or long-lasting effects. However, tetanus is completely preventable through regular vaccinations.

Causes. A toxin produced by the bacterium *Clostridium tetani*, which lives naturally in soil and water, causes this disease. People most commonly acquire this bacterium through open wounds caused by objects contaminated with soil.

Signs and Symptoms. Symptoms usually appear between 5 and 10 days after infection. Muscle spasms in the jaw, neck, and facial muscles are usually the first signs. Other signs and symptoms include worsening of the muscle spasms (which

spread to other body locations and may cause bone fractures), dyspnea (breathing difficulties), irritability, fever, profuse sweating, and drooling. See Figure 24-12. The diagnosis is usually based on the type of wound and the characteristic signs and symptoms of the disease. Tetanus antibody tests can also be used in diagnosis, but cultures of the wound site often produce false-negative findings.

Treatment. Administering antitoxin and antibiotics is a key treatment. Others include wound cleaning, muscle relaxants, sedation, and bed rest. The insertion of an endotracheal tube and mechanical ventilation may be needed for patients with severe breathing difficulties.

TORTICOLLIS is also known as wry neck. This disease is a cervical deformity in which the head bends toward the affected side while the chin rotates to the opposite side.

Causes. Torticollis may be acquired or congenital. It is caused by spasm or shortening of the sternocleidomastoid muscle. Breech or other difficult birth is often the cause of the congenital form as a result of the previously noted malpositioning, or from injury or scar tissue from ruptured muscle fibers before or during the birth process. The acquired form is the result of underlying disease, cervical spine injury, or chronic muscle spasms.

Signs and Symptoms. There is obvious malpositioning of the head and neck in an affected individual.

Treatment. For the congenital form, passive exercises to stretch the muscles as well as corrected head positioning during sleep (to maintain the straightening accomplished through the exercises) may be helpful. The treatment for acquired torticollis should consist of treating the underlying disease if possible. Otherwise, heat, cervical traction, a neck brace, exercise, massage, and psychotherapy to help the patient deal with the psychological and emotional effects related to the deformity are all treatment options.

FIGURE 24-12 A patient with advanced tetanus. CDC

TRICHINOSIS is an infection caused by parasites (worms).

Causes. This disease is caused by worms that are usually ingested by eating undercooked meat. Once ingested, the worms can leave the digestive tract and infect skeletal muscles, the heart, the lungs, and the brain. This disease is preventable by not eating wild animal meat. Proper cooking will also prevent trichinosis. There is no cure for this disease once the worms leave the digestive tract and infect other tissues.

Signs and Symptoms. Common symptoms include abdominal pain, diarrhea, muscle pain, fever, and pneumonia. In more serious cases, arrhythmias, heart failure, and encephalitis (swelling of the brain) can result. The diagnosis is usually based on the symptoms, a blood test to determine if there is an increase in eosinophils (white blood cells) in the blood, or a muscle biopsy that reveals the presence of the worms.

Treatment. Patients with this disease are treated with medications to kill worms in the digestive tract and with anti-inflammatory drugs to reduce muscle pain and swelling.

SUMMARY OF LEARNING OUTCOMES	
LEARNING OUTCOMES	KEY POINTS
24.1 Describe the functions of muscle.	The functions of muscles include movement, stability, control of body openings and passages, and the production of heat. Valve-like muscular structures called sphincters control the passage of substances into and out of organs like the stomach and bladder.
24.2 Compare the three types of muscle tissue, including their locations and characteristics.	The three types of muscle tissue are striated, voluntary skeletal muscle; smooth, involuntary visceral muscle; and specialized striated and involuntary cardiac muscle.
24.3 Explain how muscle tissue generates energy.	There are three ways muscles create energy. Creatine phosphate is a rapid method for muscles to create energy; aerobic respiration uses stored glucose to produce ATP in the Krebs cycle; and lactic acid production occurs when a cell is low in oxygen and converts pyruvic acid to lactic acid.

LEARNING OUTCOMES	KEY POINTS
24.4 Describe the structure of a skeletal muscle.	Skeletal muscle is composed of connective tissue, skeletal muscle tissue, blood vessels, and nerves. The coverings of skeletal muscles include fascia, tendon, aponeurosis, epimysium, perimysium, and endomysium.
24.5 Differentiate between the terms <i>origin</i> and <i>insertion</i> .	The origin of a muscle is the attachment site of the muscle to the less movable bone during muscle contraction. The insertion of a muscle is the attachment site for the muscle to the more movable bone during muscle contraction.
24.6 Identify the major skeletal muscles of the body, giving the action of each.	The major muscles of the head are the sternocleidomastoid, splenius capitis, frontalis, orbicularis oris and oculi, zygomaticus, platysma, masseter, and temporalis. The upper extremity muscles include the pectoralis major, latissimus dorsi, deltoid, subscapularis, infraspinatus, biceps brachii, brachialis, brachioradialis, triceps brachii, supinator, pronator teres, flexor carpi radialis and ulnaris, palmaris longus, flexor digitorum profundus, extensor carpi radialis longus and brevis, extensor carpi ulnaris, and extensor digitorum. The major respiratory muscles are the diaphragm and the external and internal intercostals. The abdominal muscles include the external and internal obliques, transverse abdominis, and rectus abdominis. The pectoral girdle muscles include the trapezius and pectoralis minor. The muscles of the lower extremity include the iliopsoas major; gluteus maximus, medius, and minimus; adductor longus and magnus; biceps femoris; semitendinosus and semimembranosus; rectus femoris; vastus lateralis, medialis, and intermedius; sartorius; tibialis anterior; extensor digitorum longus; gastrocnemius; soleus; and flexor digitorum longus.
24.7 Summarize the changes that occur to the muscular system as a person ages.	The common diseases of aging include arthritis, fractures, osteoporosis, and muscular decline. Aging causes a decline in strength and speed of muscle contractions. Dexterity and gripping abilities lessen, and mobility often decreases related to skeletal and muscular decline.
24.8 Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the muscular system.	There are many common diseases and disorders of the muscular system with varied signs, symptoms, and treatments. Some of these are botulism, fibromyalgia, muscular dystrophy, myasthenia gravis, rhabdomyolysis, tendonitis, tetanus, torticollis, and trichinosis.

CASE STUDY CRITICAL THINKING

Recall Ken Washington from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. Relate the benefits of exercise to the musculoskeletal system.
2. Identify the arm muscles Ken will need to strengthen.
3. The physical therapist wants Ken to strengthen the extensor digitorum longus muscle. Where is this muscle, and why does the therapist think this will help Ken's foot drop?

EXAM PREPARATION QUESTIONS

- (LO 24.2) Groups of cardiac muscle are connected by
 - Striations
 - Multi-units
 - Intercalated discs
 - Fascia
 - Myofibrils
- (LO 24.2) Skeletal muscle responds to which of the following neurotransmitters?
 - Epinephrine
 - Acetylcholine
 - Norepinephrine
 - Dopamine
 - Glucagon
- (LO 24.5) Increasing the angle of a joint produces which of the following body movements?
 - Extension
 - Plantar flexion
 - Flexion
 - Hyperextension
 - Elevation
- (LO 24.6) Which muscle acts to abduct and extend the arm at the shoulder?
 - Biceps brachii
 - Gluteus maximus
 - Triceps brachii
 - Deltoid
 - Brachioradialis
- (LO 24.6) Which muscle separates the thoracic and abdominal cavities and assists in respiration?
 - Internal/external obliques
 - Internal/external intercostals
 - Diaphragm
 - Pectoralis major
 - Serratus anterior
- (LO 24.6) Which of the following muscles assists with mastication?
 - Masseter
 - Frontalis
 - Platysma
 - Zygomaticus
 - Orbicularis oculi
- (LO 24.8) The medical term for a condition known as wry neck is
 - Tetanus
 - Fibromyalgia
 - Rhabdomyolysis
 - Tendonitis
 - Torticollis
- (LO 24.8) Trichinosis is caused by a(n)
 - Autoimmune disorder
 - Parasitic worm
 - Cervical deformity
 - Soil bacterium
 - Genetic mutation
- (LO 24.5) The attachment site for the more movable bone during muscle contraction is the
 - Origin
 - Agonist
 - Synergist
 - Insertion
 - Antagonist
- (LO 24.5) Pointing the toes downward is known as
 - Plantar flexion
 - Abduction
 - Inversion
 - Dorsiflexion
 - Pronation

MEDICAL TERMINOLOGY PRACTICE

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **myo / globin** = myo means “muscle” + globin means “protein”
MYOGLOBIN means “muscle protein.”

- | | | |
|------------------|-------------------|--------------------|
| 1. abduction | 5. eversion | 9. tendonitis |
| 2. adduction | 6. fibromyalgia | 10. myocytes |
| 3. circumduction | 7. hyperextension | 11. triceps |
| 4. dorsiflexion | 8. inversion | 12. rhabdomyolysis |

The Cardiovascular System

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	John Miller	12/5/19XX	Bee stings
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	082-09-981	Current Medications: Glyburide 2.5 mg daily, Captopril 25 mg bid, HCTZ 25 mg daily

John Miller, a 65-year-old patient, was referred to the cardiologist's office for an evaluation. The patient has a history of hypertension and had a myocardial infarction (heart attack) 4 years ago. More recently, he was diagnosed with mild congestive heart failure (CHF). Three weeks ago, on the advice of his primary care physician, he started a light exercise program for weight loss. Following exercise he has had a radiating chest pain (angina pectoris) that stopped after rest.

© McGraw-Hill Education

The condition has worsened in the last week. The cardiologist ordered a stress echocardiogram (a test that visualizes the heart during increasing stress). The stress echocardiogram results suggested that the chest pain may be due to coronary artery disease (CAD). The patient was scheduled for a cardiac catheterization the next morning. It was noted in the patient's

chart that he smokes two packs of cigarettes per day.

Keep John in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 25, you will be able to:

- 25.1** Describe the structures of the heart and the function of each.
- 25.2** Explain the cardiac cycle, including the cardiac conduction system.
- 25.3** Differentiate among the different types of blood vessels and their functions.
- 25.4** Compare the various types of circulation.
- 25.5** Explain blood pressure and tell how it is controlled.
- 25.6** Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the cardiovascular system.

KEY TERMS

- | | |
|---------------------------------|---------------------------|
| atrioventricular node (AV node) | myocardium |
| bundle of His | pericardium |
| cardiac output | pulmonary circulation |
| chordae tendineae | Purkinje fibers |
| coronary circulation | sinoatrial node (SA node) |
| diastolic pressure | stenosis |
| embolus | systemic circulation |
| endocardium | systolic pressure |
| epicardium | vasoconstriction |
| hepatic portal system | vasodilation |
| | viscosity |

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms, and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each system

3. Medical Terminology

- a. Define and use entire basic structure of medical words and be able to accurately identify in the correct context, i.e. root, prefix, suffix, combinations, spelling, and definitions
- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

► Introduction

The cardiovascular system consists of the heart and blood vessels. It pumps blood to the lungs to pick up oxygen and to the digestive system to pick up nutrients. It then delivers the oxygen and nutrients to all of the body cells. At the same time, it picks up waste products from the body cells and transports them to the lungs, kidneys, and other organs for removal from the body.

► The Heart

LO 25.1

The heart is a cone-shaped organ about the size of a loose fist. It is located within the mediastinum (central part of the chest) and extends from the level of the second rib to about the level of the sixth rib. Although many people think the heart is in the left side of the chest, it is located only slightly left of the midline of the body. The heart is bordered laterally by the lungs, posteriorly by the vertebral column, and anteriorly by the sternum. Inferiorly, the heart rests on the diaphragm.

Cardiac Membranes

The heart is enclosed by a membrane called the **pericardium**, or pericardial sac (see Figure 25-1). The pericardium has two parts. The outer part, called the *fibrous pericardium*, consists of a tough, fibrous material that helps protect the heart and anchor it in the chest. The inner part of the pericardium, which is called the *serous pericardium*, has two layers: the *parietal pericardium* and the *visceral pericardium*. The visceral pericardium is actually the outermost layer of the heart. The area

between these two layers of the pericardium is known as the pericardial cavity. It contains pericardial fluid, which reduces the friction between the membranes when the heart contracts and relaxes.

The Heart Wall

The wall of the heart (see Figure 25-2) is composed of the following three layers:

- **Epicardium.** This outermost layer is the visceral pericardium. It contains fat, which helps to cushion the heart.
- **Myocardium.** This middle layer is the thickest layer of the wall and is made primarily of cardiac muscle.
- **Endocardium.** This innermost layer is thin and very smooth. This layer contains part of the cardiac electrical conduction system, which is discussed later in this chapter.

Heart Chambers and Valves

The heart contains four hollow chambers, two on the left and two on the right (see Figure 25-3). The upper chambers of the heart are called *atria* (the singular form is *atrium*). They have thin walls and receive blood returning to the heart from the lungs and the body. The bottom chambers of the heart are the *ventricles*. The ventricles pump blood into the arteries, which send the blood to the lungs and the body. The wall that separates the left and right sides of the heart is the septum.

For the heart to function properly, the blood must move through it in only one direction. The four valves within the heart that keep blood flowing in one direction are the tricuspid and the bicuspid (mitral) valves, which are located

FIGURE 25-1 Location and membranes of the heart.

between the atria and ventricles, and the pulmonary semilunar and aortic semilunar valves, which are located between the ventricles and their arteries.

Tricuspid Valve The *tricuspid valve* has three cusps and is located between the right atrium and the right ventricle (see Figure 25-4). It prevents blood from flowing back into the right atrium when the right ventricle contracts. This valve is also called the *right atrioventricular (AV) valve*. The cusps of this valve are anchored by cord-like structures called **chordae tendineae** to bumps of cardiac muscle called *papillary muscles*. These muscles contract when the ventricles contract, closing the valve.

Bicuspid Valve The *bicuspid valve* has two cusps and is located between the left atrium and the left ventricle. It prevents blood from flowing back into the left atrium when the left ventricle contracts. This valve is also known as the *mitral valve* and the *left AV valve*. Like the tricuspid valve, the bicuspid valve also has chordae tendineae attached to papillary muscles.

Pulmonary Semilunar Valve The *pulmonary semilunar valve* is located between the right ventricle and the trunk of the pulmonary arteries. It prevents blood from flowing back into the right ventricle. Because its cusps are shaped like a half moon, this valve is called a *semilunar valve*.

FIGURE 25-2 Layers of the wall of the heart.

FIGURE 25-3 The chambers and valves of the heart are visible in this coronal section.

FIGURE 25-4 Valves viewed from a cross section of the heart.

Aortic Semilunar Valve The *aortic semilunar valve* is between the left ventricle and the aorta. It prevents blood from flowing back into the left ventricle and is also a semilunar valve.

► Cardiac Cycle

LO 25.2

One heartbeat makes up one cardiac cycle. During the course of one cardiac cycle, all four heart chambers contract and then relax. The atria contract first, then the ventricles. Here are the actions that occur:

- Right atrium contracts → tricuspid valve opens → blood flows into the right ventricle.
- Left atrium contracts → bicuspid valve opens → blood flows into the left ventricle.
- Right ventricle contracts → tricuspid valve closes, pulmonary semilunar valve opens → blood is pushed into the trunk of the pulmonary artery.
- Left ventricle contracts → bicuspid valve closes, aortic semilunar valve opens → blood is pushed into the aorta.

The following factors influence the cardiac cycle:

- Exercise. Strenuous exercise increases the heart rate because skeletal muscles need more oxygen.
- Parasympathetic nerves. The parasympathetic nerve to the heart is the vagus nerve, and it generally keeps the heart rate relatively low.
- Sympathetic nerves. The sympathetic nerves increase the heart rate during times of stress. Parasympathetic and sympathetic nerves are discussed in more detail in *The Nervous System* chapter.
- Cardiac control center. This center is located in the medulla oblongata, which is part of the brainstem. When blood pressure rises, this control center sends impulses to decrease the heart rate. When blood pressure falls, it sends impulses to increase the heart rate.
- Body temperature. An increase in body temperature usually increases the heart rate. This explains the high heart rate when a person runs a fever.

- **Potassium ions.** A low concentration of potassium ions in the blood decreases the heart rate, but a high concentration causes a dysrhythmia (abnormal heart rate).
- **Calcium ions.** A low concentration of calcium ions in the blood depresses heart actions, but a high concentration causes heart contractions called *tetanic contractions*, which are longer than normal heart contractions.

Heart Sounds

During one cardiac cycle, you can hear two heart sounds. The sounds, commonly called *lubb* and *dubb*, are generated when valves in the heart snap shut. Lubb is the first heart sound and occurs when the ventricles contract and the tricuspid and bicuspid valves snap shut. Dubb is the second heart sound and occurs when the atria contract and the pulmonary and aortic semilunar valves snap shut.

Physicians listen to heart sounds to diagnose certain conditions. For example, if an AV valve (tricuspid or bicuspid) is damaged, it will not close completely. This allows blood to leak back into the atria when the ventricles contract and produces an abnormal heart sound called a *murmur*. Murmurs may indicate serious heart conditions, although many heart murmurs are harmless.

Cardiac Conduction System

The cardiac conduction system consists of a group of structures that send electrical impulses through the heart. When

cardiac muscle receives an electrical impulse, it contracts (see Figure 25-5). The components of the cardiac conduction system are the sinoatrial node, atrioventricular node, bundle of His, and Purkinje fibers.

- **Sinoatrial node (SA node).** This node is located in the wall of the right atrium and generates an impulse that flows to the atrioventricular node. The SA node is also known as the natural pacemaker of the heart because it generates the heart's rhythmic contractions.
- **Atrioventricular node (AV node).** This node is located between the atria, just above the ventricles. After the impulse reaches the AV node, the atria contract and the impulse is sent to the bundle of His.
- **Bundle of His.** This structure, also known as the *atrioventricular*, or *AV*, *bundle*, is located between the ventricles and splits into two branches, forming the left and right *bundle branches*, before sending the electrical impulse to the Purkinje fibers.
- **Purkinje fibers.** These fibers are located in the walls of the ventricles. As the impulse flows through the Purkinje fibers, it causes the ventricles to contract.

Physicians use a test called an electrocardiogram (ECG or EKG) to tell if the cardiac conduction system is working properly. In a normal ECG, the waves shown in Figure 25-6 are produced. The first wave (P wave) indicates that an electrical impulse was sent through the atria, causing them to contract (depolarization). The Q, R, and S waves occur together and make up the QRS complex. This complex indicates that an electrical impulse was sent through the ventricles, causing them to contract (depolarization). Finally, the T wave indicates electrical changes that occur in the ventricles as they

FIGURE 25-5 In the cardiac conduction system, impulses begin at the sinoatrial (SA) node and travel through the heart in the order shown here.

relax (repolarization). You will learn more about the electrical conduction system of the heart and ECGs, including how to perform them, in the chapter *Electrocardiography and Pulmonary Function Testing*.

► Blood Vessels

LO 25.3

Blood circulation takes place in blood vessels that form a closed pathway to carry blood from the heart to cells and back again. These vessels include arteries, arterioles, veins, venules, and capillaries.

TABLE 25-1 Major Arteries of the Body

Artery	Anatomical Location or Organ Supplied
Lingual	Tongue
Facial	Face
Occipital	Back of scalp and neck
Maxillary	Teeth, jaw, and eyelids
Ophthalmic	Eye
Axillary	Armpit area
Brachial	Upper arm
Ulnar	Forearm and hand
Radial	Forearm and hand
Intercostals	Rib area
Lumbar	Posterior abdominal wall
External iliac	Anterior abdominal wall
Common iliac	Legs, gluteal area, and pelvic organs
Femoral	Thigh
Popliteal	Posterior knee
Tibial	Lower leg and foot

Arteries and Arterioles

Arteries carry blood away from the heart and are the strongest of the blood vessels. They have a thick layer of smooth muscle that can withstand the high pressure the heart exerts on them (see Figure 25-7). This pressure is necessary to carry the blood throughout the body. Small branches of arteries are called *arterioles*.

The largest artery in the body is the aorta, which receives its blood directly from the left ventricle. The aorta branches into the coronary arteries and many other major arteries that supply blood to various parts of the body. Major arteries are summarized in Table 25-1 and illustrated in Figure 25-8. Many arteries are paired, meaning there is a left and a right artery of the same name.

FIGURE 25-7 Arteries have much thicker walls than other blood vessels. (left) Cross section of an artery. (right) Cross section of a vein.

© Microscape/SPL/Science Source

FIGURE 25-8 Major arteries of the body (a. stands for *artery*).

Most arteries carry oxygenated blood. The exceptions to this are the pulmonary arteries, which carry deoxygenated blood from the heart to the lungs.

Capillaries

Capillaries are the smallest type of blood vessel. They branch off of arterioles and have walls that are only about one cell layer thick. These thin walls make the exchange of oxygen, carbon dioxide, and nutrients possible between the blood and the body cells (see Figure 25-9). In fact, capillaries are the only type of blood vessels that allow substances to move into and out of the blood. Tissues that require a lot of oxygen, such as muscle and nervous tissues, have a lot of capillaries.

The substances that move through the capillary walls include oxygen, carbon dioxide, nutrients, water, and metabolic wastes. These substances move through the walls through one of three processes: diffusion, filtration, or osmosis. These processes are described in the *Organization of the Body* chapter.

Veins and Venules

Veins are blood vessels that carry blood toward the heart. Unlike arteries, they are not under high pressure, so they do not need thick, muscular walls. Their walls are thinner than those of arteries. Because the blood in veins is not under pressure, veins have valves that prevent backflow and keep the blood moving toward the heart (see Figure 25-10).

EDUCATING THE PATIENT

Chest Pain

Chest pain, or angina, is a common reason for people to go to the emergency room or an urgent care center. Explain to patients that there are many causes of chest pain, both cardiac and noncardiac. Cardiac causes include myocardial infarction (MI, or heart attack), pericarditis, and coronary spasms. See the Pathophysiology section of this chapter for more detailed

descriptions of these causes. Noncardiac causes include heartburn, panic attacks, lung conditions, broken ribs, inflammation of the gallbladder or pancreas, and even just sore muscles. However, tell patients that all chest pain should be taken seriously, because some conditions, both cardiac and noncardiac, can be life-threatening if not treated.

Skeletal muscle contractions help move the blood through veins. When the muscles contract, they squeeze the veins and blood is pushed through them, much the way toothpaste is pushed out of a tube. The sympathetic nervous system also

influences the flow of blood through veins. If blood pressure becomes abnormally low, the sympathetic nervous system causes vein walls to constrict, which forces blood through the veins.

Venules are very small veins formed when capillaries merge together (see Figure 25-11). The venules then merge to form the veins.

Most veins carry deoxygenated blood. The exceptions to this are the pulmonary veins, which carry oxygenated blood from the lungs to the left ventricle of the heart. Large veins often have the same names as the arteries they run next to, but there are exceptions. For example, the veins next to the carotid arteries are the jugular veins.

Large veins empty blood into the superior vena cava and the inferior vena cava (plural: *venae cavae*), which are the largest veins in the body. The superior vena cava generally collects blood from veins above the heart, and the inferior vena cava collects blood from veins below the heart. The major veins are summarized in Table 25-2 and are illustrated in Figure 25-12.

The veins of the intestines carry blood from the digestive tract to the liver. The liver then processes nutrients in the blood and returns it to general circulation through the hepatic veins. The veins involved in this process are known as the **hepatic portal system**.

FIGURE 25-9 Structure of a capillary wall.

FIGURE 25-10 Venous valve: (a) valve opens when blood is flowing toward the heart and (b) valve closes to prevent blood from flowing away from the heart.

FIGURE 25-11 This light micrograph of a capillary network shows the capillaries merging to become venules.

FIGURE 25-12 Major veins of the body (v. stands for vein).

► Circulation

LO 25.4

Blood circulates through the body through three main circuits. The *pulmonary circuit* provides oxygen, the *systemic circuit* distributes the oxygen throughout the body, and the *coronary circuit* distributes the oxygen to the heart muscle.

Pulmonary Circulation

The pulmonary circuit, or **pulmonary circulation**, is the route blood takes from the heart to the lungs and back to the heart again (see Figure 25-13). The purpose of this circuit is

to remove waste gases such as carbon dioxide and replenish the blood with oxygen. When blood returns to the heart from the body cells, it is low in oxygen (deoxygenated) and rich in carbon dioxide. As described earlier in this chapter, the deoxygenated blood enters the right atrium, which delivers it to the right ventricle. The right ventricle pumps the blood through the left and right pulmonary arteries to the lungs.

In the lungs, blood picks up oxygen and gets rid of carbon dioxide. Blood rich in oxygen and low in carbon dioxide then returns to the heart through the four pulmonary veins. The pulmonary veins empty the oxygenated blood into the left atrium.

TABLE 25-2 Major Veins of the Body

Vein	Anatomical Location or Organ Drained
Jugular	Head and neck
Brachiocephalic	Head and neck
Axillary	Armpit area
Brachial	Upper arm
Ulnar	Lower arm and hand
Radial	Lower arm and hand
Intercostal	Rib area
Azygos	Thorax and abdomen
Iliac	Pelvic organs, legs, and gluteal areas
Femoral	Thighs
Popliteal	Knees
Saphenous	Legs
Hepatic	Liver to the inferior vena cava
Hepatic Portal System	
Gastric	Stomach to the liver
Splenic	Spleen, pancreas, and stomach to the liver
Mesenteric	Intestines to the liver
Hepatic portal	Gastric, splenic, and mesenteric veins to the liver

Systemic Circulation

The systemic circuit, or **systemic circulation**, is the route blood takes from the heart through the body and back to the heart. The purpose of this circuit is to deliver oxygen and nutrients to the body cells. It also picks up carbon dioxide and waste products from the body cells (see Figure 25-13).

Blood that returns from the lungs and enters the left atrium is oxygen rich (oxygenated) and has a low level of carbon dioxide. It flows from the left atrium to the left ventricle, which contracts to pump the oxygenated blood into the aorta, which branches off to various arteries to deliver the blood throughout the body.

The arteries branch into the smaller arterioles, and the arterioles branch into capillaries. In the capillaries, oxygen and nutrients picked up from the digestive system move from the blood into the body cells. Carbon dioxide and metabolic wastes move from the body cells into the blood. The blood then moves through the venules and veins and is collected into the vena cava, which delivers the blood back to the right atrium of the heart, and the whole process starts over again with pulmonary circulation.

Coronary Circulation

Coronary circulation is the part of systemic circulation that supplies oxygen and nutrients to the heart and removes carbon dioxide and other wastes. The coronary arteries branch directly off the aorta immediately after the blood leaves the left atrium (see Figure 25-14). Like all other arteries, the coronary arteries branch into smaller and smaller vessels, ending in capillaries, where oxygen and nutrients move into the heart

cells and carbon dioxide and wastes move into the blood. The blood then travels through the venules and the cardiac veins, which merge to form a large vein called the *coronary sinus*. Unlike other veins, however, the coronary sinus does not empty into the vena cava. It empties directly into the right atrium.

Blockage of one or more of the coronary arteries may cause chest pain, or angina, and may lead to myocardial infarction (MI, or heart attack) if not corrected. See the *Educating the Patient* feature and the Pathophysiology section of this chapter for more information about these disorders.

► Blood Pressure

LO 25.5

Blood pressure is the force that blood exerts on the inner walls of blood vessels. Blood pressure is highest in arteries and lowest in veins. In the clinical setting, *blood pressure* refers to the pressure in arteries.

Arterial blood pressure rises and falls as the ventricles of the heart contract and relax. It is highest when the ventricles contract. This highest point of pressure is called the **systolic pressure** or systole. When the ventricles relax, blood pressure in arteries is at its lowest. This pressure is called the **diastolic pressure** or diastole. Blood pressure is usually reported as the systolic pressure over the diastolic pressure. For example, in the blood pressure reading 120/80, 120 denotes the systolic pressure and 80 refers to the diastolic pressure.

You can feel the surge of blood through arteries when you take a pulse. The pulse is created as the artery expands when pressure increases and then subsequently relaxes as blood pressure decreases. Common places to feel a pulse are the carotid and radial arteries.

Many factors affect blood pressure, including cardiac output, blood volume, vasoconstriction, vasodilation, and blood viscosity. **Cardiac output** is the total amount of blood the heart pumps in 1 minute. As cardiac output increases, it causes an increase in blood pressure. When cardiac output decreases, blood pressure decreases accordingly.

When a person loses a large volume of blood, his blood pressure significantly decreases. If the blood pressure falls too low, the muscular walls of the arteries can constrict to increase blood pressure. This process is known as **vasoconstriction**. If a person's blood pressure is too high, the blood vessels dilate, decreasing the blood pressure. This process is known as **vasodilation**.

The **viscosity**, or thickness, of blood also plays a part in blood pressure. Under certain circumstances, such as dehydration, the blood becomes more viscous, or thicker. The thicker blood requires more energy to move and results in higher blood pressure.

Blood pressure is controlled to a large extent by the amount of blood pumped out of the heart. The amount of blood entering the heart should be equal to the amount of blood pumped out of the heart. The heart has a way to ensure that this happens. When blood enters the left ventricle, the wall of the ventricle is stretched. The more the wall is stretched, the harder it will contract and the more blood it will pump out. This is referred to as *Starling's law of the heart*. If only a small amount

FIGURE 25-13 Pathway of blood through the heart and lungs and on to other body parts. The right side of the heart delivers blood to the lungs (pulmonary circulation), and the left side delivers blood to all other body parts (systemic circulation).

FIGURE 25-14 Coronary circulation. (a) The coronary arteries and their branches supply blood to the heart muscle. (b) The cardiac (coronary) veins collect the deoxygenated blood and deposit it into the coronary sinus, which empties into the right atrium.

of blood enters the left ventricle, it will not be stretched very much and therefore will not contract very forcefully. In this case, not much blood is pumped out of the heart.

Baroreceptors also help regulate blood pressure. Baroreceptors measure blood pressure and are located in the aorta and carotid arteries. If pressure increases in these blood

vessels, this information is sent to the cardiac center in the medulla oblongata. The cardiac center then knows to decrease the heart rate, which lowers blood pressure. If pressure gets too low in the aorta, baroreceptors pick up this information and relay it to the cardiac center. The cardiac center then increases the heart rate to raise blood pressure.

PATHOPHYSIOLOGY

LO 25.6

Common Diseases and Disorders of the Cardiovascular System

HYPERTENSION, or high blood pressure, is a consistent resting blood pressure of 140/90 mm Hg or higher. It is known as the “silent killer,” because it increases a person’s risk of heart attack, stroke, heart failure, and kidney failure, sometimes without presenting symptoms that could warn the person of medical risk. The American Heart Association estimates that 73 million American adults have hypertension, with African Americans having a higher incidence than Caucasians.

Causes. Known causes and risk factors for hypertension include narrowing of the arteries, kidney disease, endocrine disorders, pregnancy, drug use (especially cocaine and amphetamines), sleep apnea, obesity, smoking, a high-sodium diet, excessive alcohol consumption, stress, diabetes, and various medications such as oral contraceptives and cold medicines. However, many of the causes of hypertension are unknown.

Signs and Symptoms. Hypertension often causes no symptoms at all. When symptoms are present, they include excessive sweating, muscle cramps, fatigue, frequent urination, headaches, dizziness, and an irregular heart rate.

Treatment. Hypertension cannot be cured, but it can be controlled. The first method of treatment is to treat the underlying causes, if they are known. For example, the patient may be placed on a low-sodium/low-cholesterol diet and may be encouraged to make lifestyle changes such as getting regular exercise, managing stress, and stopping smoking. The physician may also prescribe medications to slow the heart rate and/or dilate the blood vessels and diuretics to reduce blood volume.

Patient compliance is the key to successful management of hypertension. Because hypertension often has no symptoms, but the prescribed medications may have noticeable side effects, patients may stop taking the medications because they feel better when they do not take it. Be sure patients understand that taking the medication(s) is crucial to their treatment and long-term health. If they experience unacceptable side effects, they should tell the physician, because many options are available, and the physician may be able to prescribe a different medication that has fewer or less noticeable side effects.

DYSRHYTHMIAS are abnormal heart rhythms. The heart may beat too fast (tachycardia), too slowly (bradycardia), or irregularly. The most common type of dysrhythmia is atrial fibrillation, which is a sporadic, rapid beating of the atria that may or may not affect the ventricles. The most serious type of dysrhythmia is ventricular fibrillation, in which disorganized electrical activity in the heart causes the ventricles to quiver ineffectively instead of beating. Most sudden cardiac deaths are caused by ventricular fibrillation.

Causes. Most dysrhythmias result from abnormal flow of electrical impulses through the heart. Abnormal impulse conduction has many potential causes, including electric shock, certain medications, some herbal supplements, hypertension, previous heart attack, decreased blood flow to the heart, coronary artery disease, heart valve disorders, weakening of the heart muscle (cardiomyopathy), some genetic diseases, diabetes mellitus, sleep apnea, electrolyte (potassium, sodium, and calcium) imbalances, excess alcohol consumption, and drugs such as cocaine and amphetamines.

Signs and Symptoms. Dysrhythmias may cause signs and symptoms including shortness of breath, dizziness or fainting, an unusually fast or slow heart rate, a fluttering feeling in the chest, and chest pain.

Treatment. The first goal of treatment is to correct the underlying cause of the dysrhythmia. Other treatment options include

- Vagal maneuvers to slow the heart rate. These include holding the breath, straining (bearing down as if for a bowel movement), and putting the face in cool water.
- Medications such as beta blockers and anti-dysrhythmics.
- Pacemakers.
- Radiofrequency catheter ablation. This procedure destroys a small amount of heart tissue to change the flow of the electrical impulses through the heart.
- Maze procedure; this operation forms scars in the atria to correct the flow of electrical impulses through the heart.
- Implantation of an implantable cardioverter defibrillator (ICD) to regulate the heart rhythm.
- Surgery to correct heart defects such as narrow coronary arteries.
- Electric shock (defibrillation) to reset heart rhythms.
- Cardiopulmonary resuscitation if there is no evidence of blood flow.

ANGINA is chest pain that occurs when the heart does not receive enough oxygen to carry out its job of pumping blood

Go to CONNECT to see an animation exercise about Hypertension.

throughout the body. It is not immediately life threatening, but if the reason for the angina is not found and corrected, the angina may become unstable (difficult to treat and less responsive to medications). This type of angina is a warning of serious or life-threatening conditions.

Causes. Angina is caused by a narrowing of the coronary arteries. Arteries may become too narrow due to coronary spasms or as a result of coronary artery disease (atherosclerosis), in which fatty deposits accumulate in the arteries.

Signs and Symptoms. The pain of angina is usually described as a tight feeling in the chest. It is often brought about by stress or physical activity. When the stress or activity stops, the pain usually goes away.

Treatment. A doctor should monitor patients with angina regularly. Most patients with angina carry sublingual nitroglycerin with them to dilate the coronary blood vessels and relieve the pain. Treatment must also address the underlying cause of the angina to prevent more serious conditions such as a heart attack or stroke. The physician may order several tests to determine the cause of angina, such as an electrocardiogram (ECG), a stress test, blood tests, chest X-rays, cardiac catheterization, or an echocardiogram.

CORONARY ARTERY DISEASE (CAD), also called **ATHEROSCLEROSIS**, is an accumulation of fatty deposits in the arteries as a result of too much glucose in the blood. The deposits cause the arteries to become narrow, reducing the amount of blood that can flow through them. CAD affects more Americans than any other type of heart disease. The American Heart Association estimates that one in three American adults has one or more types of coronary artery disease.

Causes. This condition is usually caused by a buildup of fat, cholesterol, and calcium in the arteries. The risk factors for developing CAD include high levels of LDL (low-density lipoprotein) cholesterol in the blood, a diet high in fat and cholesterol, smoking, high blood pressure, obesity, a lack of exercise, and diabetes mellitus.

Signs and Symptoms. There are often no signs or symptoms until a heart attack occurs. The most common symptoms include angina, shortness of breath, tightness in the chest, fatigue, and swelling in the legs of feet (edema). As with most cardiac conditions, the first line of defense against CAD is prevention. CAD may be prevented or reduced by controlling high blood pressure and high cholesterol, not smoking, eating healthy foods, engaging in regular exercise, and treating any existing conditions such as diabetes or atherosclerosis.

Treatment. Existing CAD is treated using lipid-lowering agents such as Mevacor® or Lipitor®, aspirin therapy, and medications to slow a rapid heart rate. The patient can help by adopting a low-fat diet, exercising moderately, and not smoking. Severe CAD may require surgery such as coronary angioplasty or coronary artery bypass grafting (CABG) to repair, widen, or detour around narrowed coronary arteries.

A MYOCARDIAL INFARCTION (MI), commonly called a *heart attack*, is nonreversible damage to the heart caused by a lack of oxygen. Historically, MIs have been fatal, and they often still are, but with new treatments, more and more people survive them. However, the body cannot replace the damaged cardiac cells, so a heart attack can result in permanent damage to the heart.

Causes. The causes and contributing factors include blockage of coronary arteries as a result of atherosclerosis (CAD) and a blood clot that blocks the flow of blood through an artery. Drugs such as cocaine can cause coronary arteries to spasm, which may also cause an MI.

Signs and Symptoms. Common symptoms include recurring, squeezing chest pain or angina; pain in the shoulder, arm, back, teeth, or jaw; chronic pain in the upper abdomen; shortness of breath, especially on exertion; sweating (diaphoresis); dizziness or fainting; and nausea or vomiting.

Treatment. The first treatment, if possible, is chewing an aspirin at the onset of symptoms. In an unconscious patient who has no pulse and is not breathing, cardiopulmonary resuscitation (CPR) should be administered. Other immediate treatment options include the use of a defibrillator and thrombolytic medications to destroy the blood clots that block a coronary artery. It should be noted that thrombolytic drugs are effective only if begun within 3 hours of the first symptom, so time is crucial. Surgery (angioplasty or CABG) may be necessary to replace or repair blocked coronary arteries. Long-term treatment includes anticoagulant medications such as heparin and warfarin to thin the blood, and medications such as atenolol to slow the heart rate.

AN ANEURYSM is a ballooned, weakened arterial wall. The most common locations of aneurysms are the aorta and arteries in the brain, legs, intestines, and spleen. An aortic aneurysm is a bulge in the wall of the aorta. Most aortic aneurysms occur in the abdominal aorta (abdominal aortic aneurysm), but some occur in the thoracic aorta (see Figure 25-15). Most aortic aneurysms do not rupture; however, when they do, the resulting hemorrhage is a life-threatening emergency.

Causes. Most causes are unknown. One identified risk for developing an aneurysm is atherosclerosis, which is usually associated with a high-cholesterol diet. Smoking and obesity also increase the risk of atherosclerosis. Congenital conditions may cause an aneurysm—some individuals are born with weak aortic walls. A traumatic injury to the chest also may be a risk factor. The risk of developing an aneurysm can be reduced by not smoking, by losing excess weight, and by eating a low-fat, low-cholesterol diet. Periodic screening is an option for patients with a family history of aortic aneurysms.

FIGURE 25-15 Abdominal aneurysms can occur without symptoms, but if they rupture they are frequently life threatening.

Signs and Symptoms. There are usually no signs or symptoms of an aneurysm, although hypertension may be present. When symptoms do exist, the most common are a pulsation in the abdomen and back pain. A sudden pain in the abdomen or back, dizziness, a fast pulse, or a loss of consciousness can be a sign that an aneurysm has ruptured.

Treatment. The primary treatment is surgery to repair the aneurysm.

ENDOCARDITIS is an inflammation of the innermost lining of the heart, including the heart valves.

Causes. Bacterial infections are the most common cause of endocarditis. Patients are more susceptible to this condition if they have abnormal heart valves.

Signs and Symptoms. Common signs and symptoms include weakness, fever, excessive sweating, general body aches, difficulty breathing, and blood in the urine.

Treatment. The treatment for this condition is intravenous antibiotics followed by oral antibiotics for up to 6 weeks.

MYOCARDITIS is an inflammation of the muscular layer of the heart. It is relatively uncommon but very serious because it leads to weakening of the heart wall.

Causes. The most common cause of myocarditis is a viral infection, but it also may be caused by exposure to certain chemicals, allergens, and bacteria.

Signs and Symptoms. Signs and symptoms include fever as well as chest pains that feel like a heart attack. Difficulty breathing, decreased urine output, fatigue, and fainting also may accompany myocarditis.

Treatment. Treatment normally includes steroids to reduce inflammation, bed rest, and a low-sodium diet.

PERICARDITIS is inflammation of the pericardium, which is the group of membranes that surround the heart.

Causes. This condition is most commonly caused by complications of viral or bacterial infections. However, heart attacks and chest injuries also can lead to pericarditis.

Signs and Symptoms. Symptoms include sharp, stabbing chest pains, especially during deep breaths. Fever, fatigue, and difficulty breathing while lying down are also common symptoms.

Treatment. Diuretics are used to remove excess fluids around the heart. If bacteria caused the pericarditis, antibiotics are used as well. In chronic cases, surgery may be required to remove part of the membranes surrounding the heart. Because pericarditis can be very painful, treatment also generally includes painkillers.

CONGESTIVE HEART FAILURE (CHF) is a slowly developing condition in which the heart weakens over time. Eventually, the heart is no longer able to pump enough blood to meet the body's needs.

Causes. There are many risk factors for this condition, including smoking, being overweight, a diet high in cholesterol, a lack of exercise, atherosclerosis, history of MI, high blood pressure, a damaged heart valve, excessive alcohol consumption, and diabetes mellitus. Congenital heart defects (those present at birth) and drugs that weaken the heart (especially cocaine, heroin, and some antineoplastic drugs for cancer) also may contribute to the development of this disorder. Patients may reduce the risk factors for CHF by controlling high blood pressure and high cholesterol, not smoking, maintaining a healthy diet, engaging in regular exercise, and treating any existing atherosclerosis or diabetes.

Signs and Symptoms. Signs and symptoms include shortness of breath; constant wheezing; prominent neck veins; fluid retention that causes swelling in the legs, feet, or abdomen; nausea; dizziness; and an irregular or rapid heartbeat. (See Figure 25-16.)

Treatment. Common treatment options include medications to slow a rapid heartbeat, diuretics to decrease edema and fluid accumulation in the lungs, and medications to reduce blood pressure. In more serious cases, surgery to repair defective heart valves or other heart defects, implantation of a cardiac pacemaker, or a heart transplant may be needed.

MITRAL VALVE PROLAPSE (MVP) is a condition in which the mitral valve falls into the left atrium during systole. This prevents the valve from sealing properly. In severe cases, blood may flow back into the atrium. Although most cases are mild, MVP can become worse over time. It also increases the risk of heart valve infections and endocarditis.

FIGURE 25-16 When the heart muscle is damaged and weak, a patient will suffer symptoms of heart failure.

Causes. The cause of MVP is unknown in most cases. However, it may be hereditary, and it has been linked to autonomic nervous system disorders.

Signs and Symptoms. In mild cases, symptoms may not develop. In more severe cases, palpitations, shortness of breath, and chest pain may occur.

Treatment. No treatment is needed for mild cases. Medications are used to treat symptoms and to help prevent complications such as infection. In very severe cases, surgery may be required to repair the valve.

STENOSIS is an abnormal narrowing of a body passage. In the heart, **AORTIC STENOSIS** is a narrowing of the aortic valve, and **MITRAL STENOSIS** is a narrowing of the mitral valve. Stenosis causes these valves to fail to open fully. As a result, blood flow from the heart decreases and pressure inside the left ventricle increases. In severe cases, stenosis may cause heart dysrhythmias or congestive heart failure.

Causes. Aortic or mitral stenosis can be congenital or may occur later in life. Noncongenital cases are common in patients who have had rheumatic fever.

Signs and Symptoms. Common signs and symptoms include shortness of breath, angina, palpitations, dizziness, weakness, and fatigue.

Treatment. Mild stenosis may not need treatment. If the stenosis is severe enough to cause dysrhythmias or CHF, medications are used to control these disorders. If the patient has had rheumatic fever, antibiotics may also be prescribed. In some cases, surgery or valvuloplasty may be performed.

MURMURS are simply abnormal heart sounds. Normally, heart sounds are clear, strong, and smooth as valves close completely and blood flows over the lining of the heart with no resistance. Not all murmurs indicate a heart disorder. Murmurs are graded from 1 to 6; 1 is barely audible and the least serious.

Causes. Not all the causes of heart murmurs are known. In children, the failure of the foramen ovale or ductus arteriosus to close completely after birth can cause murmurs. Other causes include stress and defective heart valves that do not close completely.

Signs and Symptoms. The signs and symptoms vary considerably depending on the cause and severity of the heart murmur. Severe symptoms include weakness, pallor, edema (fluid retention), and other signs commonly associated with heart failure.

Treatment. In many cases, no treatment is required. Surgery to correct valvular defects or other heart defects may be needed in more serious cases.

THROMBOPHLEBITIS is a condition in which a blood clot blocks or partially blocks blood flow in a vein, causing inflammation, swelling, and pain. It most commonly occurs in the leg veins. The danger of thrombophlebitis is that the blood clot may break loose, becoming an **embolus** that moves through the circulatory system. The embolus can cause major problems, depending on where it lodges in the body. If it blocks a blood vessel in the lungs, it becomes a pulmonary embolism (obstruction in the lungs). If it blocks a coronary artery, it may cause a myocardial infarction (heart attack). If it blocks an artery in the brain, it may cause a cerebrovascular accident (stroke).

Causes. The causes and risk factors include prolonged inactivity, oral contraceptives, postmenopausal hormone replacement therapy (HRT), certain types of cancer, paralysis in the arms or legs, the presence of a venous catheter, a family history of thrombophlebitis, varicose veins, and trauma to veins.

Signs and Symptoms. The most common symptoms are tenderness and pain in the affected area; redness, swelling, and tenseness of the affected areas; fever; and a positive Homan's sign (pain behind the knee that is caused by a blood clot, when the foot is forceably dorsiflexed).

Treatment. This disorder is most often treated by applying heat to the affected area, wearing support stockings, and elevating the legs. Anti-inflammatory medications and anticoagulants may be prescribed. In some cases, surgery may be performed to remove the clot.

VARICOSE VEINS are twisted, dilated veins usually seen in the legs. They affect women more often than men. When varicose veins occur in the rectum, they are called *hemorrhoids*.

Causes. Varicose veins may be caused by prolonged sitting or standing, damage to valves in the veins, a loss of elasticity in the veins, obesity, pregnancy, oral contraceptives, or hormone replacement therapy. Family history also seems to play a part in the development of varicose veins. In some cases, varicose veins may be prevented or at least minimized through exercise and elevation of the legs.

Signs and Symptoms. Signs and symptoms include discomfort in the legs, discolorations around the ankles, clusters of veins, and enlarged, dark veins seen through skin.

Treatment. The treatment of varicose veins includes the following:

- Sclerotherapy, a procedure that prevents blood from flowing through varicose veins
- Laser surgery to prevent blood from flowing through affected veins
- Vein stripping, which involves removing affected veins
- Insertion of a catheter into the affected veins in order to destroy them
- Endoscopic vein surgery to close off affected veins

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
25.1 Describe the structures of the heart and the function of each.	The structures of the heart include the pericardium, epicardium, myocardium, and endocardium. The chambers of the heart consist of the atria (upper chambers) and the ventricles (lower chambers). The four valves within the heart are the tricuspid, the bicuspid, the pulmonary semilunar, and the aortic semilunar valves.
25.2 Explain the cardiac cycle, including the cardiac conduction system.	One cardiac cycle consists of one complete heartbeat. The atria contract and relax together, and the ventricles contract and relax together. As each chamber contracts, associated valves open and close to control the flow of blood through the heart. Contractions are initiated by the cardiac conduction system, which consists of the sinoatrial node, the atrioventricular node, the bundle of His, bundle branches, and Purkinje fibers.
25.3 Differentiate among the different types of blood vessels their functions.	Types of blood vessels include arteries and arterioles, which take blood from the heart to the body; veins and venules, which carry blood back from the body to the heart; and capillaries, which act as the connectors between the arterioles and venules. The largest artery in the body is the aorta. Other major arteries include lingual, facial, occipital, maxillary, ophthalmic, axillary, brachial, ulnar, radial, intercostals, lumbar, external iliac, common iliac, femoral, popliteal, and tibial. The largest veins in the body are the superior and inferior venae cavae. Other major veins are jugular, brachiocephalic, axillary, brachial, ulnar, radial, intercostals, azygos, iliac, femoral, popliteal, saphenous, hepatic, gastric, splenic, mesenteric, and hepatic portal.
25.4 Compare the various types of circulation.	Pulmonary circulation is the path the blood travels from the right side of the heart to the lungs and back to the left side of the heart. Its purpose is to oxygenate the blood and remove waste gases. Systemic circulation is the route blood takes from the left side of the heart, throughout the body, and back to the right side of the heart. Its purpose is to deliver oxygen and nutrients to body cells and to remove metabolic wastes from the cells. Coronary circulation delivers oxygenated blood to the coronary arteries and removes metabolic wastes from the heart muscle.

LEARNING OUTCOMES**25.5 Explain blood pressure and tell how it is controlled.****25.6 Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the cardiovascular system.****KEY POINTS**

Blood pressure is the force exerted on the inner wall of blood vessels by blood as it flows through vessels. It is highest in arteries and lowest in veins. Clinically, blood pressure is the force of blood within the arteries. Blood pressure is largely controlled by the amount of blood pumped out of the heart, but various other events also may raise and lower blood pressure.

Many different types of cardiac and blood diseases are described within this chapter. The signs, symptoms, and treatments are as varied as the diseases themselves. The last section of this chapter outlines the most common of these diseases, their signs and symptoms, and their treatments.

and is going to school for phlebotomy. When looking at her chart, you notice that she has lost 20 pounds in the last 3 months. When she was in for a checkup a week ago, Dr. Whalen ordered a series of blood tests, including helper T-cell tests and CBC with platelet count. She is in the office today to discuss the results of the tests.

Keep Cindy in mind as you study the chapter.

There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 26, you will be able to:

- 26.1** Describe the components of blood, giving the function of each component listed.
- 26.2** Explain how bleeding is controlled.
- 26.3** Differentiate among blood types A, B, AB, and O related to their compatibility.
- 26.4** Explain the difference between Rh-positive blood and Rh-negative blood.
- 26.5** Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the blood.

KEY TERMS

- | | |
|----------------|------------------|

| granulocyte | thrombus |

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.6** Compare structure and function of the human body across the life span
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms, and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each system

3. Medical Terminology

- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

► Introduction

Your blood is a type of connective tissue that is made up of multiple parts, including red and white blood cells, cell fragments called platelets, and plasma (the fluid part of the blood). The average-sized adult body contains approximately 4 to 6 liters of blood, or approximately 8% of the total body weight. Blood volume varies from person to person depending on the person's size, the amount of adipose tissue in the body, and the concentrations of certain ions in the blood. In general, partly because of their smaller size, females generally have less blood volume than males.

Blood performs many essential functions. It carries oxygen, nutrients, and hormones to cells throughout the body, and it carries carbon dioxide and other wastes away from the body cells. It also helps regulate body temperature.

► Components of Blood

LO 26.1

Red Blood Cells

Red blood cells (RBCs), also called **erythrocytes**, are biconcave-shaped cells, similar to a doughnut with a depression where the hole should be. RBCs are small enough to pass through capillaries (see Figure 26-1).

FIGURE 26-1 Red blood cells: (a) biconcave shape of red blood cells and (b) scanning electron micrograph of red blood cells.

© Creative Studios/Alamy RF

The percentage of red blood cells in a sample of blood is called the **hematocrit (Hct)**. A healthy person normally has a hematocrit level of about 45%. Almost 99% of the “formed elements,” or cells in blood, are red blood cells; white blood cells and platelets make up only about 1%. The rest of blood (approximately 55%) is plasma (see Figure 26-2).

Mature RBCs do not contain nuclei. They do, however, contain a pigment called **hemoglobin (Hgb)**. The function of hemoglobin is to carry oxygen from the lungs to the body tissues, and to carry carbon dioxide from the tissues to the lungs for release from the body. Hemoglobin that carries oxygen is called *oxyhemoglobin* and is bright red; hemoglobin that is not carrying oxygen is called *deoxyhemoglobin* and is a darker red. Often, because the deoxyhemoglobin is now carrying carbon dioxide, it is referred to as *carboxyhemoglobin*.

An RBC count consists of the number of red blood cells in 1 cubic millimeter (roughly 20 drops) of blood. A normal RBC count varies among laboratories, but a typical normal count is between 4.2 and 5.4 million RBC/cubic milliliter (mm^3) for adult males and between 3.6 million and 5.0 million RBC/ mm^3 for adult females. Because the function of an RBC is to transport oxygen throughout the body, a low count reflects a decreased ability to carry oxygen, causing a condition known as *anemia*. Likewise, if the RBC count is adequate but the amount of hemoglobin within the red blood cells is decreased, thus impairing the ability to carry adequate oxygen, anemia may also be diagnosed.

FIGURE 26-2 Centrifuged blood sample and peripheral blood smear slide seen through a microscope showing blood components.

During fetal development, RBCs are made in the yolk sac, the liver, and the spleen. However, once a baby is born, most blood cells are produced in red bone marrow by cells called *hemocytoblasts*. The average lifespan of an RBC is only about 120 days, so red bone marrow is constantly making new cells. The hormone **erythropoietin**, produced by the kidneys, stimulates the red bone marrow and is responsible for regulating the production of RBCs. The kidneys release erythropoietin when oxygen concentrations in the blood get low.

Iron is necessary to make hemoglobin. In addition to iron, vitamin B₁₂ and folic acid (vitamin B₉) are two dietary factors that affect RBC production. These vitamins are necessary for DNA synthesis, so red bone marrow, like all actively dividing tissue, is affected when DNA cannot be produced. As stated earlier, too few RBCs or too little hemoglobin can result in one of the many types of anemia, which will be discussed in more detail in the Pathophysiology: Common Diseases and Disorders of the Blood System section of this chapter.

As RBCs age, macrophages in the liver and spleen destroy them. When an RBC is destroyed, a pigment called *biliverdin* is released from the cell. The liver usually converts biliverdin into an orange-colored pigment called *bilirubin*. Bilirubin is used to make bile, which is needed for the digestion of fats. However, when there is too much bilirubin, it builds up in the bloodstream. This causes the individual’s skin and the sclera of the eyes to appear yellow-orange in color, a condition known as *jaundice* (or *icterus*).

White Blood Cells

White blood cells (WBCs), commonly called **leukocytes**, are divided into two categories: granulocytes and agranulocytes. **Granulocytes** have granules (small particles) in their cytoplasm and include neutrophils, eosinophils, and basophils. **Agranulocytes** do not have granules in their cytoplasm and include monocytes and lymphocytes. The types of WBCs and their characteristics are described in Table 26-1.

A WBC count is the number of WBCs in 1 cubic millimeter of blood. This count is normally between 5,000 and 10,000 cells. A WBC count above normal is called *leukocytosis*. This condition often results from bacterial infections. A WBC count below normal is called *leukopenia* and is caused by some viral infections and various other conditions.

A differential WBC count lists the percentages of the different types of leukocytes in a sample of blood. This is a useful test because certain diseases and conditions change the usual balance among the different types of WBCs. For example, neutrophil numbers increase at the beginning of a bacterial or viral infection, but monocyte numbers do not increase until about 2 weeks after a bacterial infection. Eosinophil numbers increase during viral or worm infections as well as with allergic reactions. In AIDS, lymphocyte numbers fall, particularly lymphocytes known as T lymphocytes or T cells. You will gain more in-depth knowledge about T cells in the chapter *The Lymphatic and Immune Systems*.

Some WBCs stay in the bloodstream to fight infections, whereas others leave the bloodstream by squeezing through blood vessel walls to reach other tissues. This squeezing of a

TABLE 26-1 Types of White Blood Cells

Cell Type	Description	Adult Normal Range % of Total WBC Count	Function
Granulocytes (Polymorphonuclear)			
 © Ed Reschke	Neutrophils have distinct nuclei with 3 or 4 lobes. They show neutral staining: tan, lavender, or pink.	60–70%	Aid in immune system defense; release pyrogens (chemicals produced by leukocytes to cause fever); phagocytize (engulf) bacteria; use lysosomal enzymes to destroy bacteria; level increases during infection and inflammation
 © Ed Reschke	Eosinophils have a bilobed nucleus and cytoplasmic granules that stain orange-red.	1–4%	Assist with inflammatory responses; secrete chemicals that destroy certain parasites; level increases with allergies and parasitic infection
 © Ed Reschke	Basophils have a bilobed nucleus and cytoplasmic granules that stain deep blue.	0–1%	Assist with inflammatory response by releasing histamine; release heparin (anticoagulant) and produce a vasodilator; count increases with chronic inflammation and during healing from infection
Agranulocytes (Mononuclear)			
 © Ed Reschke	Monocytes have large, kidney-shaped nuclei.	2–6%	Are the largest WBCs; become macrophages; phagocytize dying cells, microorganisms, and foreign substances; levels increase during chronic infections, such as tuberculosis (TB)
 © Ed Reschke	Lymphocytes have round nuclei and a minimum amount of cytoplasm. Lymphocytes may be B cells, T cells, or natural killer (NK) cells.	20–30%	B-cell lymphocytes assist the immune system by producing antibodies; T-cell lymphocytes assist the immune system through interactions with other leukocytes; NK cells quickly respond to stressed cells; lymphocyte levels increase during viral infections; see the chapter <i>The Lymphatic and Immune Systems</i>

cell through a blood vessel wall, which is called *diapedesis*, is shown in Figure 26-3.

Blood Platelets

Platelets are fragments of cells that are found in the bloodstream (refer back to Figure 26-2). Platelets are also called **thrombocytes** (thrombo = clot; cyte = cell) and are important in the blood-clotting process. Platelets come from cells called *megakaryocytes* found in red bone marrow. A normal platelet count is between 150,000 and 450,000 platelets per microliter of blood.

Blood Plasma

Plasma is the liquid portion of blood. It is mostly water but also contains a mixture of proteins, nutrients, gases, electrolytes, and waste products. The three major types of proteins in plasma are

- **Albumins**—the smallest plasma proteins; they pull water into the bloodstream to help maintain blood pressure.
- **Globulins**—transport lipids and some fat-soluble vitamins in plasma; some globulins become antibodies.
- **Fibrinogen**—an important protein for the blood-clotting process.

The term **serum** refers to the fluid that is left when all clotting factors are removed from plasma. You will learn more about serum in the *Processing and Testing Blood Specimens* chapter.

Nutrients in plasma are absorbed from the gastrointestinal tract and include amino acids, glucose, nucleotides, and lipids. Because lipids are not water soluble and because plasma is mostly water, lipids must combine with molecules called *lipoproteins* to be transported. The different types of lipoproteins are chylomicrons, very low-density lipoproteins (VLDL), low-density lipoproteins (LDL), and high-density lipoproteins (HDL). You will learn more about lipids and their effect on the body in the *Nutrition and Health* chapter.

The gases dissolved in plasma include oxygen, carbon dioxide, and nitrogen. Many electrolytes are also dissolved in plasma. They include sodium, potassium, calcium, magnesium, chloride, bicarbonate, phosphate, and sulfate. Molecules that contain nitrogen but are not proteins include amino acids, urea, and uric acid. Urea and uric acid are waste products produced by cells. Amino acids are the “building blocks” that combine to form proteins.

FIGURE 26-3 Diapedesis of white blood cells into surrounding tissue.

Bleeding Control

LO 26.2

Hemostasis refers to the control of bleeding. The medical term *hemostasis* breaks down into *hemo*, meaning “blood,” and *stasis*, meaning “stopping.” Following an injury, four major events are involved in stopping the flow of blood at the injured site:

1. Blood vessel spasm
2. Platelet plug formation
3. Blood clotting
4. Fibrinolysis, or dissolving of the clot and return of the vessel to normal function

If the blood vessel is small and the injury is limited, a blood vessel spasm alone may stop the bleeding. At the time of injury, the involved blood vessel constricts (narrows in diameter), and this decreases the amount of blood flowing through the vessel, which stops or controls the bleeding. If bleeding continues in spite of the blood vessel spasms, platelets are called into action. The torn, inner lining of the blood vessels releases chemical signals, which stimulate platelets to gather at the injury site. These platelets clump together to form a platelet plug, which further decreases the flow of blood from the injured site. This process occurs within seconds after an injury and is known as primary hemostasis.

A blood clot eventually replaces the platelet plug. The formation of a blood clot is called blood **coagulation**. In this process, the plasma protein fibrinogen is converted to fibrin. Once fibrin forms, it sticks to the damaged area of the blood vessel, creating a mesh that entraps blood cells and platelets (Figure 26-4). The resulting mass—the blood clot—stops the bleeding entirely. The clot stimulates the growth of fibroblasts and smooth muscle cells within the vessel wall. This begins the repair process, which includes the final step in hemostasis, *fibrinolysis*, ultimately resulting in the dissolution of the clot. The vessel finally returns to normal. See Figure 26-5.

When a blood vessel is injured, it is normal for a blood clot to form. However, sometimes blood clots form on the side

FIGURE 26-4 Scanning electron micrograph of a blood clot. Yellow fibrin threads are covering red blood cells.

© Science Photo Library/Alamy RF

FIGURE 26-5 Events in hemostasis.

of a blood vessel with no known injury; this abnormal blood clot is called a **thrombus**. A thrombus is dangerous because a portion of it can break off and start moving through the bloodstream. The moving portion of the thrombus is called an **embolus**. An embolus is dangerous because, as discussed in the chapter *The Cardiovascular System*, it can eventually block a small artery in the lungs, heart, or brain, causing pulmonary embolism, myocardial infarction, or CVA (stroke), respectively. All of these are serious and possibly fatal conditions if not treated, or if treatment cannot be initiated quickly enough to stop the condition from progressing.

▶ ABO Blood Types

LO 26.3

When a patient needs a blood transfusion, the blood used in the transfusion must be compatible with the patient's blood type. If it is not, antigens on the patient's RBCs will bind to antibodies in the donor's plasma. This causes the RBCs to clump, resulting in severe anemia. This clumping process is called **agglutination** (see Figure 26-6).

The most widely used system to determine blood typing and compatibility is the ABO blood group system. This system places blood into one of four groups, or types, based on the antigens present on the red blood cells.

- Type A—blood that has antigen A on the surface of its RBCs and antibody B in its plasma
- Type B—blood that has antigen B on the surface of its RBCs and antibody A in its plasma
- Type AB—blood that has both antigen A and antigen B on the surface of its RBCs but has neither antibody A nor antibody B in its plasma
- Type O—blood that has neither antigen A nor antigen B on the surface of its RBCs but has both antibody A and antibody B in its plasma

TABLE 26-2 ABO Blood Type Overview

Blood Type	Antigen Present	Antibody Present	Blood Type That Can Be Received
A	A	B	A and O
B	B	A	B and O
AB	A and B	None	All blood types
O	None	A and B	O only

The reaction between these antigens and antibodies is very specific. Antibody A binds only to antigen A, and antibody B binds only to antigen B. If a person with type A blood is given type B blood, then the antibody B in the recipient's blood will bind with the RBCs of the donor blood because those cells have antigen B on their surfaces. As a result, agglutination occurs, and the donated RBCs are destroyed. This is why a person with type A blood should not be given type B blood (and vice versa).

People with type AB blood are called *universal recipients* because most of them can receive all ABO blood types. They can receive these blood types because they lack antibody A and antibody B in their plasma, so there is no reaction with antigens A and B of the donor blood.

People with type O blood are called *universal donors* because their blood can be given to most people, regardless of the recipient's blood type. Type O blood will not agglutinate when given to other people because it does not have the antigens to bind to antibody A or antibody B. Table 26-2 summarizes the ABO blood groups. Also see Figure 26-7 for a pictorial representation of each blood type.

▶ The Rh Factor

LO 26.4

The *Rh antigen* is a protein first discovered on RBCs of the rhesus monkey, hence the name Rh. People who are Rh-positive have RBCs that contain the Rh antigen. People who are Rh-negative have RBCs that do not contain the Rh antigen. If a person who is Rh-negative is given Rh-positive blood, then the Rh-negative person's blood will make antibodies that bind to the Rh antigens. If the Rh-negative person

Type A blood

Type B blood

Type AB blood

Type O blood

FIGURE 26-7 Blood Types A, B, AB, and O.

is given Rh-positive blood a second time, the antibodies will bind to the donor cells and agglutination will occur.

Clinically, it is very important for a female to know her Rh type if she is pregnant or wishes to become pregnant. If an

Rh-negative female mates with an Rh-positive male, there is a 50% chance her fetus will be Rh-positive. When the blood of an Rh-positive fetus mixes with the blood of a mother who is Rh-negative, the mother develops antibodies against the

FIGURE 26-8 Development of antibodies in an Rh-negative woman in reaction to the blood of her Rh-positive fetus.

fetus's RBCs. Typically, the first Rh-positive fetus (infant) does not suffer any effects from these antibodies because it takes so long for the mother's body to generate them. However, if the mother conceives a second Rh-positive fetus, her antibodies will attack this fetus's blood right away. The second fetus then develops a condition called *erythroblastosis*

fetalis, and the baby is born severely anemic, often needing multiple blood transfusions at birth and often several times as a neonate (see Figure 26-8). Erythroblastosis fetalis is prevented by giving an Rh-negative woman the drug RhoGAM. RhoGAM prevents an Rh-negative mother from making antibodies against the Rh antigen.

PATHOPHYSIOLOGY

LO 26.5

Common Diseases and Disorders of the Blood System

ANEMIA is a condition in which a person does not have enough RBCs or hemoglobin in the blood to carry an adequate amount of oxygen to the body's cells. It is the most common blood disorder in the United States and can be a sign of a more serious disorder. It generally affects more women than men. Many types of anemia can be prevented through a healthy diet high in iron, vitamin B₁₂, and folic acid. Other types of anemia require medical attention for more serious, underlying conditions.

Causes. The many causes of this condition include the following:

- Iron deficiency. This is the most common cause of anemia. Iron is needed to make hemoglobin, which is the pigment that carries most oxygen in the blood. Pregnant women and women with heavy menstrual cycles are most susceptible to this type of anemia.
- Chronic blood loss. Slow blood loss can occur in conditions such as ulcers, colon polyps, or colon cancer.
- Vitamin deficiency. Vitamin B₁₂ and folic acid are needed to make enough RBCs.

- Inability to absorb vitamin B₁₂. This condition is called *pernicious anemia*. Some intestinal disorders prevent the absorption of vitamin B₁₂.
- Side effect of medication. Some oral contraceptives, seizure medications, and anti-neoplastic drugs used to treat cancer can cause anemia.
- Chronic illness. Chronic diseases like AIDS, cancer, rheumatoid arthritis, leukemia, and kidney failure can cause anemia.
- Bone marrow disorder. When the bone marrow fails to produce enough blood cells, aplastic anemia results. This is a life-threatening type of anemia. Toxins, chemotherapy, and radiation therapy can all destroy bone marrow.
- Destruction of RBCs. Some blood diseases, like sickle cell disease, cause RBCs to be destroyed faster than they can be made. These types of anemia are called *hemolytic anemias*.

Signs and Symptoms. Signs and symptoms of all forms of anemia include tiredness, weakness, pallor (paleness), tachycardia, numb or cold hands and feet, dizziness, headache, and jaundice.

Treatment. Treatment often begins with addressing the underlying causes, like an ulcer or colon polyps. Other treatment options include administering various medications, discontinuing the use of medications that can cause anemia, and blood transfusions or bone marrow transplants if defective or diseased bone marrow is the cause. For pernicious anemia, injections of vitamin B₁₂ may be necessary.

SICKLE CELL ANEMIA is a condition in which abnormal hemoglobin causes RBCs to change to a sickle (crescent) shape. These sickle-shaped RBCs get stuck in capillaries. Sickle cell anemia affects about 1 in every 500 African Americans and 1 in every 1,400 Latino Americans born in the United States.

Causes. The primary cause is hereditary. As an autosomal recessive disorder, a person with this disease must inherit a sickle cell gene from both parents. If only one sickle cell gene is inherited, the person is said to have sickle cell trait and may have only mild symptoms of the disease. However, the person with sickle cell trait may pass on the trait or the disease to his or her children. This condition may be prevented through genetic screening of the parents.

Signs and Symptoms. The many signs and symptoms include anemia, periodic episodes of pain called *crises*, chest pain, numbness in the hands or legs, fainting, fatigue, swollen hands and feet, jaundice, frequent infections, sores on the skin, delayed growth, stroke, seizures, and breathing difficulties. Retinal damage, which causes visual problems, and spleen, liver, or kidney and lung damage also may be seen.

Treatment. There is no cure for sickle cell disease. The goal of treatment is to control the effects of the disease. Treatment includes antibiotics to treat infections, blood transfusions, pain medications, bone marrow transplants, supplemental oxygen, and medications to promote the development of normal hemoglobin.

THALASSEMIA is an inherited form of anemia caused by a defective hemoglobin chain, resulting in microcytic (small), hypochromic (pale), short-lived RBCs.

Causes. The primary cause is hereditary. Patients of Mediterranean descent are most likely to carry the defective gene that causes this disease. Like sickle cell disease, thalassemia comes in two forms. *Thalassemia major* occurs when both parents send the defective gene to the child. If the child receives the gene from only one parent, *thalassemia minor* occurs. The child may have only mild symptoms but is a carrier who may pass the defective gene on to his or her children.

Signs and Symptoms. Thalassemia major is evident in infancy with anemia, fever, failure to thrive, and splenomegaly (enlarged spleen). It is confirmed by the characteristic changes in RBCs noted on microscopic examination. As the child matures, splenomegaly may interfere with breathing. In addition, skin becomes freckled or bronzed from the iron deposits created by the rapidly destroyed RBCs. Headache, nausea, and anorexia are common signs and symptoms.

Treatment. There is no cure for thalassemia. Frequent transfusions are necessary to treat the anemia caused by the destruction of the defective RBCs. A splenectomy may be recommended. Symptoms are otherwise treated as needed, including pain medication for the acute episodes known as crises, which are similar to those of sickle cell patients. Patients and their families may require counseling to help them deal with the day-to-day reality of living with this disease.

LEUKEMIA is a condition in which the bone marrow produces a large number of abnormal WBCs that prevent normal WBCs from carrying out their defensive functions. This disorder is sometimes referred to as cancer of the WBCs. There are several different kinds of leukemia: acute lymphocytic (lymphatic) leukemia, acute myelogenous leukemia, chronic lymphocytic (lymphatic) leukemia, and chronic myelogenous leukemia.

Causes. Causes include mutations (changes) in WBCs, chemotherapy for the treatment of other cancers, genetic factors (for example, the inheritance of abnormal genes), and exposure to environmental and chemical agents that cause changes in the WBCs.

Signs and Symptoms. The many signs and symptoms include fatigue, dyspnea on exertion (DOE), an enlarged liver (hepatomegaly) or spleen (splenomegaly), swollen (nontender) lymph nodes, abnormal bruising, cuts that heal slowly, frequent infections, nosebleeds, bleeding gums, chronic fever, unexplained weight loss, and excessive sweating.

Treatment. Treatment options include chemotherapy, radiation therapy, medications to strengthen the immune system, antibodies to destroy mutated WBCs, bone marrow transplant, and stem cell transplant.

POLYCYTHEMIA VERA is a disease of the bone marrow that results in an abnormally high number of blood cells, especially red blood cells, causing the blood to thicken. It occurs more often in men than in women, and it usually occurs after the age of 40.

Causes. A genetic mutation causes polycythemia. However, the cause of the mutation is not known.

Signs and Symptoms. The signs and symptoms of polycythemia include difficulty breathing and shortness of breath, dizziness, excessive bleeding, enlarged spleen, and headache. Itching and a reddened skin color, especially in the face, may also be seen.

Treatment. Treatment involves reducing the thickness of the blood. Up to a pint of blood may be removed each week

until the blood count becomes normal. Frequent blood counts are performed to monitor the blood, and further bloodletting, known as *therapeutic phlebotomy*, is performed when needed. Chemotherapy may also be used in some cases to reduce production of red blood cells, and aspirin may be prescribed to help prevent clots.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
26.1 Describe the components of blood, giving the function of each component listed.	The formed elements in blood include red blood cells responsible for oxygen and carbon dioxide transport; white blood cells responsible for working with the immune system by fighting infection; and platelets, which assist in blood clotting. The liquid component of blood is called <i>plasma</i> ; when all clotting factors and formed elements are spun out of plasma, the remaining liquid is called <i>serum</i> .
26.2 Explain how bleeding is controlled.	Hemostasis is the control of bleeding. Four basic processes occur during hemostasis: blood vessel spasm, platelet plug formation, blood coagulation, and fibrinolysis. Coagulation is the formation of a blood clot. It involves fibrinogen converting to fibrin, which sticks to the damaged area of the blood vessel, creating a mesh that traps blood cells and platelets.
26.3 Differentiate among blood types A, B, AB, and O related to their compatibility.	The four ABO blood types are A, B, AB, and O, based on the type of antigen present on the RBCs. Types A, B, and O have antibodies in the plasma that react to other antigens, so each of these types must receive only the same blood type during a transfusion. Type AB is considered the universal receiver because it has no antibodies in the plasma and is therefore compatible with all blood types. Type O has no antigens, so it is considered the universal donor. However, because it has antibodies to both antigen A and antigen B, people with type O blood can receive only type O blood.
26.4 Explain the difference between Rh-positive blood and Rh-negative blood.	The Rh factor (named for the rhesus monkey) is an antigen that may be attached to any blood type. Its importance arises during transfusions (Rh-negative blood cannot receive Rh-positive blood) and during pregnancy if the mother is Rh-negative but the fetus received the Rh-positive antigen from the father. The first fetus will not be much affected; unless treated, however, any subsequent Rh-positive fetus will suffer effects of erythroblastosis fetalis because the mother's blood developed antibodies against the Rh-positive factor during the initial pregnancy.
26.5 Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the blood.	The blood can be affected by many common diseases and disorders with varied signs, symptoms, and treatments. Some of these include anemia, leukemia, sickle cell anemia, polycythemia vera, and thalassemia.

CASE STUDY CRITICAL THINKING

© Red Chopsticks/Getty Images RF

Recall Cindy Chen from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. What information about Cindy's blood can be gained by the CBC and platelet count?
2. A helper T cell is a type of white blood cell (WBC). Why would information about Cindy's WBCs, particularly T cells, be of interest to her physician, considering her HIV status?

EXAM PREPARATION QUESTIONS

1. (LO 26.1) Which of the following is the hormone responsible for regulating the production of RBCs?
 - a. Hemoglobin
 - b. Erythropoietin
 - c. Biliverdin
 - d. Oxyhemoglobin
 - e. Hematocrit
2. (LO 26.1) Which blood cell type does not contain a nucleus?
 - a. RBCs
 - b. Eosinophils
 - c. Agranulocytes
 - d. Basophils
 - e. Neutrophils
3. (LO 26.2) Which term refers to control of bleeding?
 - a. Hemoglobin
 - b. Hematocrit
 - c. Platelets
 - d. Agglutination
 - e. Hemostasis
4. (LO 26.2) The other term for blood coagulation is
 - a. Plug
 - b. Fibrin
 - c. Clotting
 - d. Granulation
 - e. Agglutination
5. (LO 26.3) Which blood type is the universal donor?
 - a. Blood type A
 - b. Blood type B
 - c. Blood type AB
 - d. Blood type O
 - e. Rh-negative
6. (LO 26.3) Which process could indicate a transfusion reaction because of a blood typing mismatch?
 - a. Coagulation
 - b. Clotting
 - c. Hemorrhage
 - d. Bleeding
 - e. Agglutination
7. (LO 26.4) Which combination could be a problem for an unborn fetus?
 - a. Rh-negative mom/Rh-positive dad/first pregnancy
 - b. Rh-positive mom/Rh-negative dad/first pregnancy
 - c. Rh-negative mom/Rh-positive dad/second pregnancy
 - d. Rh-positive mom/Rh-negative dad/second pregnancy
 - e. Rh-negative mom/Rh-negative dad/second pregnancy
8. (LO 26.4) RhoGAM is used to prevent
 - a. Iron deficiency anemia
 - b. Erythroblastosis fetalis
 - c. Leukemia
 - d. Transfusion reactions
 - e. Hemophilia
9. (LO 26.5) Which of the following is *not* a cause of anemia?
 - a. Vitamin B₁₂ deficiency
 - b. Blood loss
 - c. RBC destruction
 - d. Bone marrow destruction
 - e. Low WBC count
10. (LO 26.5) Which blood disorder is hereditary?
 - a. Sickle cell anemia
 - b. Thalassemia
 - c. Leukemia
 - d. Sickle cell anemia and thalassemia
 - e. Thalassemia and leukemia

M E D I C A L T E R M I N O L O G Y P R A C T I C E

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **hemo / rrhage** = hemo means “blood” + rhagge means “excessive flow”

HEMORRHAGE means “excessive flow of blood.”

- | | | |
|------------------|-----------------------------|---------------|
| 1. erythrocytes | 5. anemia | 9. leukemia |
| 2. leukocytes | 6. thrombocytes | 10. hemolytic |
| 3. granulocytes | 7. hemostasis | 11. hematoma |
| 4. agranulocytes | 8. erythroblastosis fetalis | 12. venogram |

The Lymphatic and Immune Systems

27

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Cindy Chen	7/15/19XX	NKA
PATIENT INFORMATION	Attending	MRN	Other Information
	Alexis N. Whalen, MD	324-86-542	T-cell count 396 cells/mm ³ Retest in 3 months

Cindy Chen is a 28-year-old Asian female complaining of inability to sleep and nervousness. She tested positive for HIV in 2014 and is asymptomatic and on antiviral drugs. She currently lives with her aunt and is going to school

to become a phlebotomist. When looking at her chart, you notice she has lost 20 pounds since her last visit. Dr. Whalen has ordered a series of blood tests, including helper T-cell tests and CBC with platelet count.

Keep Cindy in mind as you study the chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 27, you will be able to:

- 27.1** Describe the pathways and organs of the lymphatic system.
- 27.2** Compare the nonspecific and specific body defense mechanisms.
- 27.3** Explain how antibodies fight infection.
- 27.4** Describe the four different types of acquired immunities.
- 27.5** Describe the causes, signs and symptoms, and treatments of major immune disorders.

KEY TERMS

- | | |
|----------------------------|--|
| anaphylaxis | lymph |
| antibodies | lymph node |
| antibody-mediated response | lymphocytes |
| antigens | lymphokines |
| autoimmune disease | macrophages |
| cell-mediated response | major histocompatibility complex (MHC) |
| complements | monokines |
| cytokines | natural killer (NK) cells |
| hapten | phagocytosis |
| immunoglobulins | spleen |
| innate immunity | thymus |
| interstitial fluid | tonsils |

- I.C.4** List major organs in each body system
- I.C.6** Compare structure and function of the human body across the life span
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms, and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

► Introduction

Your immune system works as a personal coat of armor, responsible for protecting your body against bacteria, viruses, fungi, toxins, parasites, and cancer. This important system, present in every human being, works with the organs of the lymphatic system—the thymus, spleen, and lymph nodes—to clear the body of various disease-causing agents.

► The Lymphatic System

LO 27.1

The lymphatic system is a network of connecting vessels that collects the interstitial (or tissue) fluid found between cells. These lymphatic vessels then return this fluid, now called **lymph**, to the bloodstream. See Figure 27-1. The lymphatic system also picks up lipids and fat-soluble vitamins (A, D, E, and K) from the digestive tract and transports them to the bloodstream. The third function of the lymphatic system is to protect the body against disease-causing agents.

Interstitial (Tissue) Fluid and Lymph

Fluid constantly leaks out of blood capillaries into the spaces between cells. This fluid is high in nutrients, oxygen, and small proteins. Most of this fluid is picked up by body cells. However, some of the fluid persists between cells. Increased tissue hydrostatic pressure moves **interstitial (tissue) fluid** into the lymphatic vessels. This fluid is destined to become lymph.

Lymphatic Vessels and Lymph Circulation

The lymphatic vessels transport lymph and excess fluid away from the interstitial spaces toward the heart. Smaller lymphatic capillaries join to form larger lymphatic vessels.

Lymphatic Capillaries The lymphatic capillaries are similar in structure to blood capillaries except that lymphatic capillaries are larger in diameter and facilitate drainage of interstitial fluids—fluids between the cells—from the tissues. This is facilitated by the thin, very permeable lymphatic capillary walls, which are lined by a single layer of squamous epithelial cells called endothelium. The epithelial cells of the lymphatic capillary wall overlap, creating flap-like valves that allow fluid to enter the capillary but do not allow fluid to exit under normal conditions. However, under some conditions, lymph can leak out of the vessels, causing *edema*, or fluid buildup, in the interstitial spaces. Lymphatic capillaries converge to form lymphatic trunks, which in turn merge to form lymphatic ducts. This is similar to the structure of the venous system, but lymphatic vessels have thinner walls and more valves than do veins. The lymphatic pathway is illustrated in Figure 27-2.

Lymphatic Trunks and Ducts Lymphatic trunks are typically named after the region in which they are found. For example, the *jugular trunks* (left and right) drain the head and neck region. The *lumbar trunk* drains the lymph from the lower extremities, the *subclavian trunk* drains the upper limbs, and the *bronchomediastinal trunk* drains lymph from the thorax. The trunks eventually empty into the two lymphatic ducts. The *right lymphatic duct* receives lymph from the upper right side of the body. It empties its contents into the right internal jugular and right subclavian veins. These veins return the lymph to the right atrium by way of the superior vena cava. The other duct is the *thoracic duct*, which is the largest lymphatic vessel in the body. It drains lymph from all parts of the body that are not drained by the right lymphatic duct. The thoracic duct begins at the level of the second

FIGURE 27-1 Schematic flow of lymph from the lymphatic capillaries to the bloodstream.

lumbar vertebra. The thoracic duct passes through the diaphragm beside the aorta. The thoracic duct empties into the junction of the left internal jugular and left subclavian veins (see Figure 27-3).

Lymph is moved along by two pumps and flows in only one direction—toward the heart. The *skeletal muscle pump* utilizes skeletal muscle contractions to move the lymph toward the heart. The other pump is the *respiratory pump*, which utilizes pressure changes in the thorax to assist circulation. Along its way to the venous blood, lymph will pass through more than 600 *lymph nodes* throughout the body.

Lymphoid Organs and Tissues

Lymphoid organs and tissues are widespread throughout the body and consist of lymph nodes, the thymus, and the spleen.

FIGURE 27-2 Lymphatic pathway.

FIGURE 27-3 Areas drained by the right lymphatic duct (shaded) and thoracic duct (not shaded).

Lymph Nodes Lymph nodes are very small, glandular structures that usually cannot be felt, or palpated, very easily (Figure 27-4). They are located along the paths of larger lymphatic vessels and are spread throughout the body. A major exception is that no lymph nodes are found in the nervous system. There is a greater concentration of nodes in certain places in the body such as the cervical (neck), axillary (armpit), inguinal (groin), supratrochlear (medial side of the elbow), pelvic, thoracic, and aortic (thorax) nodes. The indented side of a lymph node is called the hilum. Nerves and blood vessels enter the node through the hilum. The lymphatic vessels that carry lymph to the node and are located opposite the hilum are called afferent (meaning “toward”) lymphatic vessels. About four or five afferent vessels are associated with each node. The lymphatic vessels that carry lymph out of a node are called efferent (meaning “away from”) vessels.

A lymph node usually has only one or two efferent vessels. Because more lymph enters the node than can exit at one time, lymph tends to concentrate in the node and pressure builds up that assists in the filtration process. Lymph nodes are also surrounded by a fibrous capsule of connective tissue. The lymph node is divided into an inner portion called the medulla and an outer portion called the cortex.

Two important cell types are found inside the nodes—macrophages and lymphocytes. Together these form the *lymph nodules*, the functional units of the lymph node. Lymph nodules are found in the cortex of the lymph node. **Macrophages** digest unwanted pathogens in the lymph and the **lymphocytes** are part of the immune response against the pathogen. Lymph nodes are also responsible for the generation of some lymphocytes.

When someone has a viral or bacterial infection, he or she may have *lymphadenitis*, an inflammation of the lymph nodes. Any disease of the lymph nodes is called *lymphadenopathy*. The terms *lymphadenitis* and *lymphadenopathy* are

often used interchangeably by healthcare professionals, but it is important to remember that the suffix *-itis* refers to inflammation and the suffix *-pathy* refers to disease. Other causes of lymphadenopathy are autoimmune disease and malignancy.

Thymus The **thymus** is a soft, bilobed organ located behind the sternum, just below the thyroid gland and above the heart in the mediastinum (a space between the right and left lungs) (See Figure 27-5). The thymus is large in the infant and reaches its maximum size of 1 to 2 ounces when the child is about 2 years of age. After adolescence the thymus starts to atrophy (waste away) or *involute* (turn in on itself). In older adults, the thymus is tiny, almost nonexistent. Starvation or acute disease can sometimes accelerate this process. The outer portion of the thymus is called the cortex. This is where T lymphocytes (T cells) that have been produced in the bone marrow proliferate. They then move to a more central portion of the gland called the medulla, where they mature. The thymus also produces the hormone *thymosin*, which stimulates the production of mature lymphocytes.

Spleen The **spleen** is the largest lymphoid organ. It is located in the upper-left quadrant of the abdominal cavity, just below the diaphragm and behind the stomach. It is protected by the rib cage and normally is not palpable. The spleen is divided into lobules with two types of tissues: white pulp and red pulp. The white pulp is concentrated with lymphocytes similar to those seen in lymph nodes. Red pulp has an abundance of red blood cells, lymphocytes, and macrophages. The spleen filters blood in much the same way that lymph nodes filter lymph. The spleen also removes senescent (old), worn-out red blood cells from the bloodstream. If the spleen is injured or becomes enlarged due to disease, a condition known as *splenomegaly*, the spleen is often removed (a *splenectomy*) to prevent rupture of the spleen if trauma were to occur. When a splenectomy is performed, the patient’s liver takes over most of its functions. Table 27-1 summarizes the characteristics of the major organs of the lymphatic system.

Lymph Nodules Lymph nodules are masses of lymphoid tissue not surrounded by a capsule. These are often referred to as *mucosa-associated lymphoid tissue (MALT)* because they are distributed in the connective tissue of mucosa. The **tonsils** are three sets of lymphoid tissue. These three sets include

- Pharyngeal tonsils, or adenoids, located at the junction of the mouth and oropharynx.
- Palatine tonsils, located at the junction of the nasal cavity and nasopharynx.
- Lingual tonsils, located at the base of the tongue.

The appendix, or *vermiform appendix*, is usually located in the lower-right quadrant at the junction of the large and small intestines. It was once thought that the appendix had no function. We now know it is part of the immune system. There are also lymph nodules in the small intestine.

FIGURE 27-4 Section of a lymph node.

TABLE 27-1 Major Organs of the Lymphatic System

Organ	Location	Functions
Thymus	In the mediastinum posterior to the upper portion of the body of the sternum	Houses lymphocytes; differentiates thymocytes into T lymphocytes
Spleen	In the upper-left portion of the abdominal cavity inferior to the diaphragm, posterior and lateral to the stomach	Blood reservoir; houses macrophages that remove foreign particles, damaged red blood cells, and cellular debris from the blood; contains lymphocytes
Lymph nodes	In groups or chains along the paths of the larger lymphatic vessels	Filter foreign particles and debris from lymph; produce and house lymphocytes that destroy foreign particles in lymph; house macrophages that engulf and destroy foreign particles and cellular debris carried in lymph

Defenses Against Disease

LO 27.2

An infection is the presence of a pathogen—a disease-causing agent such as a bacterium, virus, toxin, fungus, or protozoan—in or on the body. The body has mechanisms called nonspecific defenses, or **innate immunity**, to protect itself from pathogens in general. The body also has mechanisms to protect itself against specific pathogens; these mechanisms, called immunities, are considered specific defenses.

Nonspecific Defenses

The nonspecific mechanisms that protect the body against pathogens include species resistance, mechanical and chemical barriers, and phagocytosis. Fever and inflammation are also effective in protecting the body from invading organisms. These defenses are described in this section and summarized in Table 27-2.

Species Resistance Species resistance means that a species typically gets only diseases unique to that species. For example, humans do not get diseases that affect plants. Humans also do not get most diseases that affect animals.

FIGURE 27-5 The bilobed thymus is located between the lungs and superior to the heart; the spleen is inferior to the diaphragm and posterior and lateral to the stomach.

TABLE 27-2 Nonspecific Defenses

Species resistance	A species is resistant to certain diseases to which other species are susceptible.
Mechanical barriers	Unbroken skin and mucous membranes prevent the entrance of some infectious agents; fluids wash away microorganisms before they can firmly attach to tissues.
Chemical barriers	Enzymes in various body fluids kill pathogens; pH extremes and high salt concentration also harm pathogens; interferons induce production of other proteins that block reproduction of viruses, stimulate phagocytosis, and enhance the activity of cells to resist infection and the growth of tumors; defensins damage bacterial cell walls and membranes; collectins attach to microbes; complement stimulates inflammation, attracts phagocytes, and enhances phagocytosis.
Phagocytosis	Neutrophils, monocytes, and macrophages engulf and destroy foreign particles and cells.
Fever	Elevated body temperature inhibits microbial growth and increases phagocytic activity.
Inflammation	Inflammation is a tissue response to injury that helps prevent the spread of infectious agents into nearby tissues.
Natural killer cells	Natural killer cells are a distinct type of lymphocyte that secretes perforins that lyse virus-infected cells and cancer cells.

Mechanical Barriers The covering of the body (skin) and the linings of the tubes of the body (mucous membranes) provide mechanical barriers against pathogens. Intact skin is impermeable or resistant to most pathogens. Intact mucous membranes, although generally impermeable, do permit the entry of a few pathogens.

Chemical Barriers Chemicals and enzymes in body fluids provide chemical barriers that destroy pathogens. For example, acids in the stomach destroy pathogens that are swallowed. Lysozymes in tears destroy pathogens on the surface of the eye. Salt in sweat kills bacteria, and interferon in blood blocks viruses from infecting cells.

Phagocytosis Phagocytes are cells that surround and destroy pathogens and unwanted debris in the body. Neutrophils and monocytes are the most active phagocytes in blood. They can also leave the bloodstream to attack pathogens in other tissues. When a monocyte leaves the bloodstream, it becomes a macrophage, which is simply a larger phagocytic cell. The process of destroying pathogens by this method is called **phagocytosis**.

Fever An elevated body temperature is a fever. It causes the liver and spleen to take iron out of the bloodstream. Many pathogens need iron to survive in a body, so when their iron sources are gone, they die. Fever also activates phagocytic cells in the body to attack pathogens.

Inflammation When an area of the body becomes injured or infected with a pathogen, inflammation can result. In inflammation, blood vessels in the injured area dilate and become leaky. Because blood vessels dilate, more blood enters the area, bringing phagocytic white blood cells (WBC) to the area to attack the pathogen. The blood also brings proteins to replace injured tissues and clotting factors to stop any bleeding. The clotting factors also “wall off” the area so that pathogens cannot spread. Because blood vessels become leaky, more fluid accumulates in the injured area, which leads to edema. The excess fluid often irritates pain receptors. The four cardinal signs of inflammation are redness, heat, swelling, and pain.

Natural Killer Cells Natural killer (NK) cells are another type of lymphocyte. They primarily target cancer cells but also protect the body against many types of pathogens. Like cytotoxic T cells, NK cells kill harmful cells on contact. They secrete chemicals that produce holes in the membranes of harmful cells, which cause the cells to burst. Unlike B cells and T cells, NK cells do not have to recognize a specific antigen to start destroying pathogens. B cells and T cells are discussed later in the chapter.

Specific Defenses

Specific defenses are called immunities. They protect the body against specific pathogens. For example, a person who has chickenpox develops a specific defense that prevents him or her from getting chickenpox again. However, this specific defense does not protect the person from any other disease. For example, a person who has measles will not get the measles again but if she is exposed to the mumps virus and has not been vaccinated, she can get the mumps.

Antigens are simply defined as foreign substances in the body. Pathogens have many antigens on their surfaces. The immune system is programmed to recognize antigens in the body. Foreign substances in the body that are too small to start an immune response by themselves are called **haptens**. Haptens often attach to proteins in the blood, where they are then able to trigger an immune response. Penicillin is an example of a hapten.

Antibodies and complements are the major proteins involved in specific defenses. **Antibodies** are proteins the body produces in response to specific antigens, and **complements** are proteins in serum that work with antibodies to eliminate or destroy antigens.

Lymphocytes and macrophages are the major WBCs involved in specific defenses. The cells of the lymphatic system produce proteins known as **cytokines**, which assist in immune response regulation. Cytokines are special messenger proteins that send signals to other parts of the immune system

so that the immune response is coordinated. These messengers can act as on/off switches for certain immune cells or they can attract immune cells to a specific area of need, such as a wound, that needs immune cells to heal. Lymphocytes and macrophages produce cytokines known as **monokines**. Monokines assist in regulation of the immune response by increasing B-cell production and stimulating red bone marrow to produce more WBCs.

B Cells and T Cells Two major types of lymphocytes are B cells and T cells. Although both B cells and T cells circulate in the blood, most of the lymphocytes in blood are T cells. B cells and T cells are also found in lymph nodes, the spleen, the thymus, the lining of digestive organs, and bone marrow.

Both T cells and B cells recognize antigens in the body; however, they respond to antigens in different ways. T cells bind to antigens on cells and attack them directly. This type of response is called a **cell-mediated response**. T cells also respond to antigens by secreting cytokines called **lymphokines**, which increase T-cell production and directly kill cells that have antigens.

B cells, on the other hand, do not attack antigens directly. They respond to antigens by becoming plasma cells. The plasma cells then make antibodies against the specific antigen. The antibodies attach to antigens in the humors (fluids) of the body; this response is called a humoral, or **antibody-mediated, response**. B cells become activated when a specific antigen binds to receptors on their surfaces. Each group of B cells recognizes only one type of antigen. Once activated, B cells divide to make plasma cells and memory B cells. Plasma cells make antibodies, which travel through the fluids of the body and bind to the antigens that activated the B cells. Memory B cells trigger a faster and stronger immune response the next time the person is exposed to the same antigen because they already know to respond to the antigen—just as you know what to expect the second time you play a computer game and can thus play faster and better. (See Figures 27-6 and 27-7.)

As seen in Figure 27-6, before a T cell can respond to an antigen, it must be activated. T-cell activation begins when a macrophage ingests and digests a pathogen that has antigens on it. The macrophage then takes some of the antigens from the pathogen and puts them on its cell membrane next to a large protein complex called a **major histocompatibility complex (MHC)**. Every human being has a unique MHC (similar to an internal fingerprint), and it is present on every cell in the body. A T cell that has a receptor for the antigen recognizes and binds to the antigen and the MHC on the surface of the macrophage. The T cell is now activated and begins to divide to form other types of T cells and T memory cells. It is important to note that T cells cannot be activated without macrophages and MHC proteins. MHC is also involved in recognizing foreign cells versus host cells. This is important in keeping the immune system from attacking the body's own cells by mistake.

Some activated T cells form cytotoxic T cells that are important in protecting the body against viruses and cancer cells.

Other activated T cells become helper T cells that carry out many important roles in immunity. Helper T cells increase antibody formation, memory cell formation, B-cell formation, and phagocytosis. Some activated T cells become memory T cells that “remember” the pathogen that activated the original T cell. When a person is later exposed to the same pathogen, memory cells trigger an immune response that is more effective than the first immune response. The production of memory cells prevents a person from suffering from the same disease twice.

► Antibodies

LO 27.3

Antibodies are also called **immunoglobulins**. The following is a list of different types of immunoglobulins (Ig):

- IgA is an antibody found in secretions of the body like breast milk, sweat, tears, saliva, and mucus. It prevents pathogens from entering the body.
- IgD is an antibody found on the cell membranes of B cells. IgD has an important role in activating basophils, a type of white blood cell.
- IgE is an antibody found wherever IgA is located. It is involved in triggering allergic reactions.
- IgG is an antibody that primarily recognizes bacteria, viruses, and toxins. It can also activate complements.
- IgM is a large antibody that primarily binds to antigens on food, bacteria, or incompatible blood cells. It also activates complements.

When antibodies bind to antigens, they take one of the following actions:

- They allow phagocytes to recognize and destroy antigens.
- They make antigens clump together, causing them to be destroyed by macrophages. This is how incompatible blood cells are destroyed.
- They cover the toxic portions of antigens to make them harmless.
- They activate complements, which are proteins in serum that attack pathogens by forming holes in them. Complement proteins also attract macrophages to pathogens and can stimulate inflammation.

► Immune Responses and Acquired Immunities

LO 27.4

A primary immune response occurs the first time a person is exposed to an antigen. This response is slow and takes several weeks to occur. In this response, memory cells are made. A secondary immune response occurs the next time a person is exposed to the same antigen. This response is quick and usually prevents a person from developing a disease from the antigen. Memory cells carry out the secondary immune response.

A person is born with very few immunities but normally develops or acquires them as long as his immune system is healthy. The four types of immunities a person can acquire are (1) naturally acquired active immunity, (2) artificially acquired

FIGURE 27-6 T-cell and B-cell activation. (1) A macrophage displays an antigen on its cell membrane. (2) A helper T cell binds to the antigen on the macrophage and becomes activated. (3) An activated helper T cell releases cytokines to help an activated B cell proliferate. Notice that the B cell must also bind to an antigen to become activated.

active immunity, (3) naturally acquired passive immunity, and (4) artificially acquired passive immunity.

Naturally Acquired Active Immunity

A person develops this immunity by being naturally exposed to an antigen and subsequently making antibodies and memory cells against the antigen. Having an infectious disease caused by pathogens, leads to the development of this type of immunity, which is usually long-lasting.

Artificially Acquired Active Immunity

A person develops this immunity by being injected with a pathogen and subsequently making antibodies and memory cells against the pathogen. Immunizations and vaccines cause this type of immunity, which is also usually long-lasting.

Naturally Acquired Passive Immunity

A person receives this immunity from his mother. When a mother breast-feeds, she passes antibodies to her baby through breast milk. A mother also passes antibodies to her baby across the placenta, which is a short-lived immunity.

Artificially Acquired Passive Immunity

A person receives this immunity when she is injected with antibodies made by another person or an animal. For example, if a person is exposed to hepatitis A at a restaurant, she can be given antibodies from a person who has previously had the disease. The treatment must be administered in the first 2 weeks after exposure. This type of immunity is short-lived.

FIGURE 27-7 An activated B cell multiplies to become memory cells and plasma cells. Plasma cells secrete antibodies.

PATHOPHYSIOLOGY

LO 27.5

Common Diseases and Disorders of the Immune System

As science and medicine develop a better understanding of the immune system and its relationship to causing disease, multiple diseases and disorders involving many body systems are now thought to have an autoimmune component.

An **autoimmune disease** is one in which the body begins to attack its own antigens. This happens when the immune system is no longer able to recognize itself and mounts an immune response against its own body cells. Examples of autoimmune diseases include scleroderma (integumentary system), rheumatoid arthritis (skeletal system), multiple sclerosis (nervous system), glomerulonephritis (urinary system), Crohn's disease (digestive system), and insulin-dependent (Type 1) diabetes mellitus (endocrine system). Although the reason is unknown, autoimmune

disorders affect women almost 75% of the time, often during childbearing years.

A number of diseases and disorders can challenge the immune system. Among them, HIV infection, AIDS, cancer, and allergies are the most significant. HIV and AIDS are discussed in the *Microbiology and Disease* chapter. In this section, you will focus on specific immune system disorders. For other diseases with possible or probable autoimmune components, please refer to the appropriate body system in Appendix III.

CANCER is defined as the uncontrolled growth of abnormal cells. Healthy cells normally know when to stop reproducing, but cancer cells have lost this ability. Occasionally, normal cells create growths, but these are benign, which means they are not cancerous. Cancer cells, however, often form growths called malignant tumors, which may become fatal. In many cases,

these cancerous cells or tumors damage normal cells of tissues and organs, causing organ systems to fail.

At least 200 different types of cancers are known. In the United States, the three most common cancer types in men are prostate, lung, and colon cancer. The three most common types in women are breast, lung, and colon cancer. Lung cancer kills more people in the United States than any other type of cancer.

Causes. The causes of cancer are mostly unknown, but certain risk factors have been identified, including a suppressed immune system, radiation, tobacco, and some viruses. Many other factors are suspected. One of the best ways to prevent cancer is to avoid smoking and other known risk factors. A factor known to cause the formation of cancer is called a carcinogen.

Diagnosis. Most cancers are diagnosed with a biopsy, which is a removal of tissues for examination. CT scans are also used to help diagnose most cancer types. Other diagnostic tests include blood counts, an analysis of blood chemistry, and X-rays.

Signs and Symptoms. The symptoms of different types of cancer vary, but the following symptoms are usually observed in most types: fever, chills, unintended weight loss, fatigue, and a general sense of not feeling well.

Treatment. The treatment of cancer differs depending on the type and stage of cancer. The stage of cancer refers to how large a tumor is and how far cancer cells have spread throughout the body. Table 27-3 provides a summary of cancer staging.

If tumors are localized and have not spread, the cancer can often be treated successfully by surgically removing the tumor. Other treatment options are chemotherapy, radiation therapy, newer immune therapies, and transplants, such as bone marrow transplant, which may be successful for curing certain types of cancer. Even if a cancer cannot be cured, its progression can sometimes be slowed, allowing the patient to live additional years.

ALLERGIES cause an allergic reaction, which is an immune response to a substance, like pollen, that is not normally

harmful to the body. An allergy can also be an excessive immune response. Substances that trigger allergic responses are called *allergens*. Allergic reactions involve IgE antibodies and mast cells. IgE antibodies increase and respond when exposed to an allergen (trigger). The IgE antibodies bind to these allergens and cause mast cells to release histamine and heparin. These chemicals trigger allergic reactions such as sneezing or wheezing, or worse.

To help prevent this reaction, a patient receiving allergy shots is injected with tiny amounts of the allergen. This causes the body to produce IgG antibodies that will prevent IgE antibodies from binding to the allergen. IgG antibodies do not trigger immune responses because they do not activate mast cells.

Most allergies do not cause life-threatening conditions, but some do. One life-threatening condition that can result is **anaphylaxis**, when blood vessels dilate so quickly that blood pressure drops too fast for organs to adjust. Without treatment, patients may go into anaphylactic shock and die.

Signs and Symptoms. The signs and symptoms of allergies vary depending on what part of the body is exposed to allergens. Inhaled allergens often cause a runny nose, sneezing, coughing, or wheezing. Ingested allergens may cause nausea, diarrhea, or vomiting. Skin allergens cause rashes. Allergens in the blood, like penicillin, are often the most life-threatening for people who are allergic to them because the allergens can affect many organ systems.

Treatment. Many allergies are effectively treated with over-the-counter medications called antihistamines. Prescription-strength antihistamines are also available. Various types of nasal sprays and decongestants can also reduce allergy symptoms. When a person experiences anaphylaxis, an injection of epinephrine is usually an effective treatment. Epinephrine causes vasoconstriction, which increases blood pressure.

Go to CONNECT to see an animation exercise about Immune Response: Hypersensitivity.

TABLE 27-3 Cancer Staging

Stage	Description
Stage 0	Very early cancer. Cancer cells are localized in a few cell layers.
Stage I	Cancer cells have spread to deeper cell layers, or some may have spread to surrounding tissues.
Stage II	Cancer cells have spread to surrounding tissues but are considered contained in the primary cancer site.
Stage III	Cancer cells have spread beyond the primary cancer site to nearby areas.
Stage IV	Cancer cells have spread to other organs of the body.
Recurrent	Cancer cells have reappeared after treatment.

ACQUIRED IMMUNODEFICIENCY SYNDROME (AIDS) is the development of severe signs and symptoms caused by the human immunodeficiency virus (HIV) as it destroys lymphocytes—particularly T lymphocytes—which leaves the immune system weakened and susceptible to many other diseases. Because a person may be infected with HIV for years before developing symptoms, it is important for all high-risk individuals to be tested.

Causes. AIDS is caused by the human immunodeficiency virus (HIV).

Signs and Symptoms. Symptoms of AIDS include T-cell counts below 200 (normal is more than 400); fever; diaphoresis; weakness; weight loss; frequent infections, including herpetic ulcers of the mouth, skin, and genitals; TB; yeast

infections of the mouth, esophagus, and vagina; meningitis; and encephalitis. Cytomegalovirus (CMV), a specific type of herpetic virus, may also affect the eyes and other internal organs. Kaposi's sarcoma is a skin cancer commonly seen in AIDS patients.

Treatment. Although there is no cure for AIDS, treatments are available in the United States that significantly delay the progression of the disease for many patients. These treatments include the use of various antiviral drugs, but many of these drugs have serious side effects. Antibiotics are also used to treat infections.

CHRONIC FATIGUE SYNDROME (CFS) is a condition in which a person feels severe tiredness that cannot be relieved by rest and is not related to other illness.

Causes. The causes are primarily unknown, although a unique virus known as the Epstein-Barr virus (EBV) is suspected as a possible cause. This condition may also be caused by an autoimmune response against the nervous system.

Signs and Symptoms. The most common symptom is severe fatigue. Other signs and symptoms include mild fever, sore throat, tender lymph nodes in the neck or armpit, general body aches, joint pain, sleep disturbances, and depression.

Treatment. Treatment includes antiviral drugs, medications to treat the depression associated with this condition, and pain medications.

LYMPHEDEMA is the blockage of the lymphatic vessels that drain excess fluids from various areas of the body.

Causes. This condition may be caused by parasitic infections, trauma to the vessels, tumors, radiation therapy, cellulitis (a skin infection), and surgeries such as mastectomies and biopsies in which lymphoid tissues have been removed.

Signs and Symptoms. The common symptom is tissue swelling that lasts longer than a few days or increases over time.

Treatment. Treatment options include compression stockings for swelling in the legs or arms, elevation of the affected limb, and surgery to remove abnormal lymphoid tissue. Physical therapy and massage therapy are also helpful in the early stages of lymphedema to spread the fluid into surrounding tissues for reabsorption.

MONONUCLEOSIS is also known as mono. Because it frequently affects teenagers and is a highly contagious viral infection spread through the saliva of the infected person, it has earned the nickname "the kissing disease." Mono is also spread through coughing and sneezing.

Causes. Mononucleosis can be caused by either the Epstein-Barr virus or cytomegalovirus (CMV).

Signs and Symptoms. Unexplained fever, extreme fatigue, and sore throat are common. Other symptoms include weakness; headache; and swollen, tender lymph nodes (lymphadenopathy).

Treatment. Rest, proper nutrition, gargling with warm salt water, and taking acetaminophen for fever usually result in

recovery from acute symptoms in a week or two, although complete recovery may take a month or longer.

SYSTEMIC LUPUS ERYTHEMATOSUS (SLE), commonly referred to as lupus, is an autoimmune disorder that affects a few or, sometimes, many organ systems of the body. In this condition, people produce antibodies that target their own cells and tissues. As with many autoimmune disorders, lupus affects women much more often than men.

Causes. This disorder may be caused by some drugs or by bacterial infections. Except for its autoimmune component, its actual cause is unknown.

Signs and Symptoms. The list of signs and symptoms is extensive and may include any or all of the following:

- Fatigue
- General body aches
- Fever
- Weight loss (anorexia)
- Hair loss
- Arthritis
- Numbness of the fingers and toes
- "Butterfly" rash on the face
- Sensitivity to sunlight (photophobia)
- Vision problems
- Nausea
- Nosebleeds (epistaxis)
- Headaches
- Mental disorders
- Seizures
- Abnormal blood clots
- Chest pains
- Inflammation of heart tissues (carditis)
- Anemia
- Shortness of breath
- Fluid accumulation around the lungs
- Renal failure
- Blood in the urine (hematuria)

Treatment. Treatment options include anti-inflammatory medications, including steroids, and protective clothing and creams to prevent damage from sunlight. Dialysis, immunosuppressive medications, and kidney transplants may be necessary for more serious cases.

CELIAC DISEASE is an immune reaction to eating gluten, making it a diagnosable autoimmune disorder. Gluten is a protein substance found in wheat, barley, and rye.

Causes. When a person with celiac disease eats more than 10 milligrams of gluten (about 1/8 of a teaspoon of flour), this triggers an autoimmune reaction that causes the individual's body to attack the small intestinal mucosa. In the long term, if left untreated, a person with celiac disease will lose the ability to absorb nutrients and will increase his or her risk of developing another autoimmune disorder and/or cancer of the small intestine.

Signs and Symptoms. The intestinal damage from eating gluten can cause weight loss, bloating, and sometimes diarrhea. If left untreated, eventually the brain, nervous system, bones, liver, and other organs can be deprived of vital nutrients. In children, malabsorption in the small intestine can affect growth and development. The intestinal irritation can cause stomach pain, especially after eating.

Treatment. A strict, lifelong gluten-free diet is the only treatment. This means not only eating gluten-free foods but also

being aware of gluten cross-contamination. For example, oats do not naturally contain gluten but can be contaminated during growth and manufacturing. The FDA regulations for labeling products as gluten free have tightened in the last 5 years. However, individuals with celiac disease should be aware that gluten can even be present in small quantities in more obscure additives, such as malt flavoring.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
27.1 Describe the pathways and organs of the lymphatic system.	The lymphatic system is composed of pathways known as lymphatic vessels. In addition to the lymphatic vessels, the organs of the lymphatic system include lymph nodes, located throughout the body; the thymus, in the mediastinum; and the spleen, located in the upper-left quadrant of the abdominal cavity.
27.2 Compare the nonspecific and specific body defense mechanisms.	Nonspecific body defenses include species resistance, mechanical and chemical barriers, phagocytosis, fever, and inflammation. Specific defenses are immunities, or defenses, against specific antigens created by B cells, T cells, and natural killer (NK) cells.
27.3 Explain how antibodies fight infection.	Antibodies work in the following ways: phagocytosis, antigen clumping, covering (inactivating) toxic portions of antigens, and activating complements. Antibodies are also known as immunoglobulins. IgA prevents pathogens from entering the body; IgD controls B-cell activity; IgE works with IgA in triggering allergic reactions; IgG recognizes bacteria, viruses, and toxins and activates complements; and IgM binds to antigens on food, bacteria, or incompatible blood cells. IgM also activates complements.
27.4 Describe the four different types of acquired immunities.	The four types of immune response are naturally acquired active immunity, such as when a person becomes ill and develops immunity; artificially acquired active immunity, as when an injection is given against a pathogen, preventing illness; naturally acquired passive immunity, which occurs when an infant has its mother's immunity for a short while after birth and through breast milk; and artificially acquired passive immunity, which occurs after injection of antibodies such as an antivenom.
27.5 Describe the causes, signs and symptoms, and treatments of major immune disorders.	There are many common diseases and disorders of the immune system with varied signs, symptoms, and treatments. Some of these include cancer, allergies, AIDS and HIV infection, and other autoimmune diseases, in which the body attacks its own antigens.

CASE STUDY CRITICAL THINKING

© Red Chopsticks/Getty Images RF

Recall Cindy Chen from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. Explain the function of the helper T cell within her immune system.
2. Why might Cindy be more susceptible to other diseases than the general population?
3. If Cindy is HIV positive, does that mean she has visible symptoms? Why or why not?
4. Is Cindy's T-cell count normal? (Her T-cell count is reported in Other Information.) What T-cell count would be considered a symptom of AIDS?

EXAM PREPARATION QUESTIONS

1. (LO 27.1) The fluid found between cells is called
 - a. Lymph
 - b. Interstitial fluid
 - c. Plasma
 - d. CSF
 - e. Cellular fluid
2. (LO 27.1) The thoracic duct collects lymph from which of the following areas of the body?
 - a. Right side of the head and neck
 - b. Right side of the chest
 - c. Right leg
 - d. Right arm
 - e. Left side of the head and neck
3. (LO 27.2) Innate immunity is the other name for which type of body protection?
 - a. Specific immunity
 - b. Artificial immunity
 - c. Humoral immunity
 - d. Nonspecific immunity
 - e. Temporal immunity
4. (LO 27.2) The types of white blood cells that are involved in specific defenses are lymphocytes and
 - a. Macrophages
 - b. Neutrophils
 - c. Eosinophils
 - d. Basophils
 - e. Leukophils
5. (LO 27.3) Which of the following cells do not attack antigens directly
 - a. Lymphokines
 - b. B cells
 - c. T cells
 - d. NK cells
 - e. Alpha cells
6. (LO 27.3) Which antibody is involved in triggering allergic reactions?
 - a. IgA
 - b. IgD
 - c. IgE
 - d. IgM
 - e. IgB
7. (LO 27.4) A patient has been exposed to hepatitis A at a local restaurant and is treated with antibodies from a patient who previously had hepatitis A. What type of acquired immunity does this provide?
 - a. Naturally acquired active immunity
 - b. Artificially acquired active immunity
 - c. Naturally acquired passive immunity
 - d. Artificially acquired passive immunity
 - e. Humorally acquired active immunity
8. (LO 27.5) Which of the following is a known carcinogen?
 - a. Family history
 - b. Weight gain
 - c. Sedentary lifestyle
 - d. Smoking
 - e. Black vegetables
9. (LO 27.5) Which of the following is a life-threatening condition that can be caused by allergies?
 - a. Anaphylaxis
 - b. AIDS
 - c. Lymphedema
 - d. Mononucleosis
 - e. HIV
10. (LO 27.5) An example of an autoimmune disease is
 - a. Chickenpox
 - b. Rheumatoid arthritis
 - c. Influenza
 - d. Atherosclerosis
 - e. Strep throat

| 3. cytotoxic | 7. lymphedema | 11. phagocytosis |
| 4. immunoglobulin | 8. lymphocyte | 12. thymectomy |

The Respiratory System

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Mohammad Nassar	5/17/20XX	Animal dander?
PATIENT INFORMATION	Attending	MRN	Other Information
	Elizabeth H. Williams, MD	423-90-687	Recently became sexually active

Mohammad Nassar is a 16-year-old male complaining of increased difficulty breathing over the last 2 days. From his chart, you see that Mohammad has a history of asthma and is on a maintenance dose of albuterol 4 mg extended-release tablets twice a day. Mohammad states that he spent the weekend with his girlfriend's family at their summer

© David Sacks/Getty Images

home, with the family's two dogs and a cat. He is thinking that exposure to the pets may be connected to the worsening of his asthma. Dr. Williams has ordered a peak expiratory flow test and has referred Mohammad for allergy testing.

Keep Mohammad in mind as you study the chapter. There will be questions at the end of the chapter based on

the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 28, you will be able to:

- 28.1** Describe the structure and function of each organ in the respiratory system.
- 28.2** Describe the events involved in the inspiration and expiration of air.
- 28.3** Explain how oxygen and carbon dioxide are transported in the blood.
- 28.4** Compare various respiratory volumes and tell how they are used to diagnose respiratory problems.
- 28.5** Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the respiratory system.

KEY TERMS

alveoli	nasopharynx
bronchi	oropharynx
bronchioles	paranasal sinuses
dyspnea	pharynx
epiglottis	pleura
expiration	respiratory capacity
glottis	respiratory volume
inspiration	surfactant
laryngopharynx	thoracocentesis
larynx	thoracostomy
nares	thorax
nasal conchae	trachea

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.6** Compare structure and function of the human body across the life span
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including:
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structures and functions
- b. Describe common diseases, symptoms and etiologies as they apply to each body system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- a. Define and use entire basic structure of medical words and be able to accurately identify in the correct context, i.e. root, prefix, suffix, combinations, spelling, and definitions
- b. Build and dissect medical terms from roots/ suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

► Introduction

The function of the respiratory system is to move air in and out of the lungs. This process may be called ventilation, respiration, or breathing. The respiration process works with the cardiovascular system to deliver oxygen (O_2) to body cells via the bloodstream. It also removes a waste product—carbon dioxide (CO_2)—from the blood. This exchange of oxygen and carbon dioxide in the lungs is called *external respiration*. This same exchange, when it occurs within the hemoglobin of the red blood cells (RBCs), is known as *internal respiration*.

► Organs of the Respiratory System

LO 28.1

The organs of the respiratory system are the nose, pharynx, larynx, trachea, bronchial tree (including the bronchi and bronchioles), and lungs (see Figure 28-1). The nose is made of bones and cartilage and the skin covering them. The openings of the nose are the nostrils, which in medicine are referred to as the **nares**. The hairs within the nares prevent large particles from entering the nose.

The Nasal Cavity and Paranasal Sinuses

The nasal cavity is simply the hollow space behind the nose. The nasal cavity is divided into left and right portions by the cartilaginous nasal septum. Most of the nasal cavity is

lined with a mucous membrane that warms and moistens air as it passes through the cavity. Three structures called **nasal conchae** extend from the lateral walls of the nasal cavity and support this mucous membrane by increasing the surface area of the nasal cavity. The three conchae are simply named by their position, as superior, middle, and inferior nasal conchae.

The nasal cavity is also lined with cells that possess *cilia*, which are microscopic, hair-like projections from the mucous membrane. As mucus traps dust and other particles in the nasal cavity, the cilia push the mucus toward the pharynx, where it is swallowed. The enzymes of the stomach then destroy these foreign particles and pathogens, thus helping to protect the respiratory system from disease.

The **paranasal sinuses** are air-filled spaces within the skull bones that open into the nasal cavity. The paranasal sinuses reduce the weight of the skull and equalize pressure between the inside of the skull and the outside environment. The sinuses also give your voice its tone. When your paranasal sinuses are “stopped up” with mucus, they cause the tone of your voice to change. The bones of the skull that contain the sinuses include the frontal, sphenoid, ethmoid, and maxillae bones. When sinus membranes become inflamed due to allergies or infection (sinusitis), they swell, which results in a sinus headache.

The Pharynx

The **pharynx** is a dual organ of the respiratory system as well as the digestive system. It consists of three separate sections:

FIGURE 28-1 (a) Organs of the respiratory system and (b) a bronchiole with alveolar sac, covered by capillary network, whole, and in cross section.

The **nasopharynx** is located at the junction of the nasal cavity and the pharynx; the **oropharynx** is the area at the junction of the oral cavity (mouth) and pharynx; and finally, the **laryngopharynx** is the area of the pharynx that contains the larynx, or “voice box.” During inspiration, air flows from the nasal or oral cavity into the pharynx. From the pharynx, air flows into the larynx.

The Larynx and Vocal Cords

The **larynx** sits superior to and is continuous with the trachea, or windpipe. It moves air into and out of the trachea

and produces the sounds of a person’s voice. The larynx consists mostly of cartilage and muscle tissue. There are three cartilages in the larynx (see Figure 28-2). The largest cartilage is called the *thyroid cartilage*, and it forms the anterior wall of the larynx. During the puberty of a male, testosterone causes the thyroid cartilage to enlarge to produce the “Adam’s apple.” A smaller cartilage called the *epiglottic cartilage* forms the framework of the **epiglottis**, the flap-like structure that closes off the larynx during swallowing so that food and liquids do not enter the respiratory system. The third cartilage of the larynx is called the *cricoid cartilage*.

FIGURE 28-2 (a) Anterior view of larynx, (b) posterior view of larynx, and (c) photograph of the vocal cords and glottis.

© CNRI/Phototake

It forms most of the posterior wall of the larynx and a small part of the anterior wall.

The vocal cords stretch between the thyroid cartilage and the cricoid cartilage. The opening between the vocal cords is called the **glottis** (see Figure 28-2c). The upper vocal cords are referred to as *false vocal cords* because they do not produce sound. The lower vocal cords are called *true vocal cords* because muscles stretch and relax them to produce different types of sounds. When the true vocal cords are stretched, the voice becomes higher in pitch. When they are relaxed, the voice becomes lower in pitch. Males tend to have thicker vocal cords, which is why their voices are generally deeper than female voices.

The Trachea, Bronchi, and Bronchioles

The **trachea** (windpipe) is a tubular organ made of rings of cartilage and smooth muscle. It extends from the larynx to the bronchi. The trachea is lined with cells that possess cilia that constantly move mucus up to the pharynx and the esophagus, where it is swallowed. Mucus traps bacteria, viruses, and other harmful substances a person inhales. The digestive juices of the stomach then destroy the harmful substances.

Smoking destroys cilia, so the only way a smoker can get mucus out of his trachea is to cough. Smokers often feel the urge to cough more frequently than nonsmokers in an effort to move mucus to the pharynx.

The distal end of the trachea branches and starts a series of tubes called the *bronchial tree*. The first branches off the trachea are called primary, or main stem, **bronchi**. The branches of the primary bronchi are called secondary bronchi. The secondary bronchi branch into tertiary bronchi. Tertiary bronchi then branch into **bronchioles**. At the ends of the bronchioles are air sacs called **alveoli** (see Figure 28-1b).

Alveoli are thin sacs made of only one layer of simple squamous epithelial cells and are surrounded by capillaries. They are considered the “working tissue” of the lung because it is in the alveoli that the exchange of oxygen and carbon dioxide takes place. Many physicians refer to the alveoli as the *pulmonary parenchyma* (*parenchyma* means “working tissue”). Through the process of diffusion, red blood cells in the capillaries release carbon dioxide into the alveoli. Conversely, the alveoli release oxygen into the blood through the thin walls of the capillaries. This exchange is known as *internal* or *cellular respiration*.

The Lungs

The lungs are two cone-shaped organs that contain connective tissue, the bronchial tree, nerves, lymphatic vessels, and many blood vessels. The right lung is larger than the left because the heart is also located in the left **thorax**, or chest area. The right lung is divided into three lobes, known as the right upper, middle, and lower lobes. The left lung is divided into the left upper and lower lobes. The double-walled

membrane that surrounds the lungs is called the **pleura**. The outer membrane is known as the parietal pleura, and the innermost membrane is the visceral pleura. The pleura produces a slippery, serous fluid called *pleural fluid* that helps decrease friction as the membranes move against each other during breathing.

The lungs themselves contain the bronchial tree and alveoli. Some alveolar cells secrete a fatty substance called **surfactant** that helps maintain the inflation of the alveoli so that they do not collapse in on themselves between inspirations. Premature infants often suffer from respiratory distress syndrome (RDS) (formerly known as hyaline membrane disease—see the Pathophysiology section) because their lungs do not yet create enough surfactant. This causes them to often have great difficulty maintaining adequate lung inflation.

► The Mechanisms of Breathing LO 28.2

Breathing, or pulmonary ventilation, consists of two events—**inspiration** and **expiration**. During inspiration, or inhalation, air, which is 21% oxygen, enters through the

naso- or oropharynx through the sinuses into the larynx, trachea, and bronchial tree, eventually reaching the alveoli of the lungs. Air flows into the airways during inspiration because the thoracic cavity enlarges. When the thoracic cavity enlarges, pressure decreases in the cavity. The atmospheric pressure outside the body is greater than the pressure inside the cavity, and air passively flows from an area of high pressure to an area of low pressure. The following events enlarge the thoracic cavity and therefore lead to inspiration (see Figure 28-3a):

- The diaphragm contracts. As it does so, it flattens, which increases the amount of space in the thoracic cavity.
- The intercostal muscles raise the ribs, further enlarging the thoracic cavity.

During expiration, or exhalation, air rich with carbon dioxide flows out of the airways. Air flows out because the thoracic cavity becomes smaller, which increases the pressure inside the cavity. When the pressure inside the cavity becomes greater than the atmospheric pressure, air flows out. The following events lead to expiration (see Figure 28-3b):

FIGURE 28-3 (a) Events of inspiration and (b) events of expiration.

- The diaphragm relaxes. As it does so, it domes up into the thoracic cavity, which decreases the space in the cavity.
- The intercostal muscles lower the ribs; this further decreases the size of the thoracic cavity.

Breathing is controlled by the respiratory center of the brain, which is located in the pons and medulla oblongata. The medulla oblongata controls both the rhythm and the depth of breathing. The pons controls the rate of breathing.

Other factors that affect breathing are the carbon dioxide levels in the blood and the pH of the blood. When carbon dioxide levels rise in the blood, the rate and depth of breathing increase. The rate and depth of breathing also increase when the blood pH drops. Fear and pain also increase the breathing rate. Breathing rapidly and deeply is called *hyperventilation*, which decreases the amount of carbon dioxide in the blood. However, it should be noted that in patients with chronic obstructive pulmonary disease (COPD), decreased oxygen levels stimulate respiratory rates. Therefore, giving a patient with COPD a high level of oxygen may actually decrease his or her breathing reflex.

The inflation reflex also helps to regulate the depth of breathing. Stretch receptors in pleural membranes are activated when the lungs are stretched past a certain point. This triggers a decrease in the depth of breathing to prevent over-inflation of the lungs.

Normal, everyday situations also alter our breathing patterns. Consider these common occurrences:

- Coughing. A deep inspiration occurs and the glottis is closed. As the air forces the glottis open, a rush of air is forced up to clear the lower respiratory passages.
- Sneezing. The same process occurs as in coughing except that air is moved to the nasal passages by lowering the uvula. This causes a clearing of the upper respiratory passages.
- Laughing. A deep breath is expelled in short bursts, expressing happiness.
- Crying. The same respiratory process occurs as in laughing, but the expression is one of sadness.
- Hiccups. Also spelled hiccoughs, these are spasmodic contractions of the diaphragm against a closed glottis. Interestingly, the purpose for this is not known.
- Yawning. A deep inspiration that increases the amount of air brought to the alveoli aids in blood oxygenation.

- Speaking. Air is forced through the larynx, vibrating the vocal cords. Words are formed by the tongue, lips, and teeth, allowing for verbal communication.

Also, consider the common patient complaint of snoring. See the feature *Educating the Patient* for more information.

► The Transport of Oxygen and Carbon Dioxide in the Blood

LO 28.3

Once oxygen gets into the bloodstream, most of it binds to the heme portion of hemoglobin in red blood cells. Hemoglobin bound to oxygen is called *oxyhemoglobin* and is bright red in color. Some oxygen stays dissolved in plasma and does not bind to hemoglobin, but this is generally a lesser amount than that which attaches to the RBCs. Carbon dioxide also binds to hemoglobin, but at the globin or protein portion of the hemoglobin, forming *carboxyhemoglobin*. However, unlike oxygen, much of the carbon dioxide enters the plasma for transport through the body, after being converted into carbonic acid by the RBCs. Carbonic acid can quickly be converted into the buffer bicarbonate as needed by the blood to maintain its narrow, constant pH level of 7.35–7.45 (see *The Cardiovascular System* chapter).

Carbon monoxide is a colorless, odorless gas. Poisonous to humans, it is particularly dangerous because it binds to the same heme area of hemoglobin as does oxygen. In fact, it binds more tightly to this molecule than oxygen. When hemoglobin is exposed to carbon monoxide, the carbon monoxide “overrules” oxygen, leading to carbon monoxide poisoning.

► Respiratory Volumes

LO 28.4

The amount of air that moves into and out of the lungs when a person breathes is called **respiratory volume**. A person's respiratory volume varies depending on the depth and intensity of the breaths the person is taking. **Respiratory capacity**, or the amount of air the lungs can hold, is another common measure of respiratory health. It can be calculated by adding certain respiratory volumes together. In fact, several different measurements related to respiratory volume and capacity are commonly used to assess a person's lungs (see Table 28-1). You will learn more about these respiratory volumes and the process of measuring them in the *Electrocardiography and Pulmonary Function Testing* chapter.

TABLE 28-1 Respiratory Air Volumes and Capacities

Name	Volume*	Description
Tidal volume (TV)	500 mL	Volume moved into or out of the lungs during a respiratory cycle
Inspiratory reserve volume (IRV)	3,000 mL	Volume that can be inhaled during forced breathing in addition to resting tidal volume
Expiratory reserve volume (ERV)	1,100 mL	Volume that can be exhaled during forced breathing in addition to resting tidal volume
Residual volume (RV)	1,200 mL	Volume that remains in the lungs at all times
Inspiratory capacity (IC)	3,500 mL	Maximum volume of air that can be inhaled following exhalation of resting tidal volume: $IC = TV + IRV$
Functional residual capacity (FRC)	2,300 mL	Volume of air that remains in the lungs following exhalation of resting tidal volume: $FRC = ERV + RV$
Vital capacity (VC)	4,600 mL	Maximum volume of air that can be exhaled after taking the deepest breath possible: $VC = TV + IRV + ERV$
Total lung capacity (TLC)	5,800 mL	Total volume of air that the lungs can hold: $TLC = VC + RV$
Forced vital capacity (FVC)	Varies depending on gender, age, and height	Amount of air exhaled with force after inhaling as deeply as possible
Peak expiratory flow (PEF)	Varies depending on gender, age, and height	Greatest rate of flow during forced exhalation

*Values are typical for a tall, young adult.

EDUCATING THE PATIENT

Snoring

Snoring occurs when the muscles of the palate, tongue, and throat relax. Airflow then causes these soft tissues to vibrate. These vibrating tissues produce the harsh sounds characteristic of snoring.

Snoring causes daytime sleepiness and is sometimes associated with a condition known as obstructive sleep apnea (OSA). In OSA, the relaxed throat tissues cause airways to collapse, which prevents a person from breathing. Snoring affects approximately 50% of men and 25% of women older than age 40. The common causes of snoring include the following:

- Enlargement of the tonsils or adenoids
- Being overweight
- Alcohol consumption
- Nasal congestion
- A deviated (crooked) nasal septum

The severity of snoring varies among people. The Mayo Clinic's Sleep Disorders Center uses the following scale to determine the severity of snoring:

- Grade 1: Snoring can be heard from close proximity to the face of the snoring person.
- Grade 2: Snoring can be heard from anywhere in the bedroom.

- Grade 3: Snoring can be heard just outside the bedroom with the door open.
- Grade 4: Snoring can be heard outside the bedroom with the door closed.

You can educate patients about making lifestyle modifications and using aids to help reduce their snoring:

- Lose weight.
- Change the sleeping position from the back to the side.
- Avoid the use of alcohol and medications that cause sleepiness.
- Use nasal strips to widen the nasal passageways.
- Use dental devices to keep airways open.

In addition, patients may benefit from a continuous positive airway pressure (CPAP) machine if obstructive sleep apnea (OSA) is diagnosed as the underlying cause of the snoring. A CPAP machine, uses a mask attached to a pump that forces air into their passageways while they sleep. If these therapies are not effective, patients may need surgery such as a uvulotomy to trim excess tissues in the throat, or laser surgery to remove a portion of the soft palate.

Common Diseases and Disorders of the Respiratory System

ALLERGIC RHINITIS is a hypersensitivity reaction to various airborne allergens.

Causes. There are many causes, which may be seasonal, such as hay fever, or continual, such as those caused by dust, molds, colognes, cigarette smoke, animal dander, and mites.

Signs and Symptoms. There are numerous signs and symptoms, which may include sneezing; itchy, watery eyes; red, swollen eyelids; congested nasal mucous membranes; and nasal discharge.

Treatment. Treatment commonly includes the use of over-the-counter (OTC) antihistamines and decongestants. Severe cases may be treated with prescription medication such as Allegra® and OTC medication such as Zyrtec®. Patients should also avoid known allergens. Air filters and air conditioners assist in keeping allergen counts down. Seeking the assistance of an allergist for desensitization injections may be an option for long-term management.

ASTHMA is a condition in which the tubes of the bronchial tree become obstructed as a result of inflammation.

Causes. The causes include allergens (pollen, pets, dust mites, etc.), cigarette smoke, pollutants, perfumes, cleaning agents, cold temperatures, and exercise (in susceptible individuals).

Signs and Symptoms. Symptoms include difficulty breathing, a tight feeling in the chest, wheezing, and coughing, all of which can cause a feeling of suffocation and increased anxiety.

Treatment. Treatment includes avoiding allergens, using steroidal and nonsteroidal inhalers such as Advair® and Flovent®, and taking oral medications such as Singulair® and other bronchodilators to reduce inflammation. See Figure 28-4. Patients should avoid smoky environments; those who smoke should stop. Strongly scented items such as perfumes, hair products, and cleaning agents should also be avoided.

ATELECTASIS is more commonly called collapsed lung. It may occur after abdominal or thoracic surgery or because of pleural effusion, which may consist of blood, fluid, air, or pus in the pleural cavity. The medical names for these conditions are hemothorax (blood in the pleural cavity), hydrothorax (fluid), pneumothorax (air), and pyothorax (pus).

Causes. These include underlying cystic fibrosis and COPD in which patients may have a chronic form of atelectasis. Cancer patients and those with inflammatory conditions such as

FIGURE 28-4 Individuals with asthma may use an inhaler with steroidal or nonsteroidal medication for treatment.
© Royalty-Free/Corbis

pleurisy (pleuritis) may also be subject to chronic atelectasis. Acute atelectasis may occur after any injury to the ribs or trauma to the thorax. Postsurgical patients are also susceptible.

Signs and Symptoms. These include **dyspnea** (difficulty breathing), cyanosis (a blue coloration of skin and mucous membranes), diaphoresis (excessive perspiration), anxiety, tachycardia, and intercostal muscle retraction. Depending on the cause of the atelectasis, there may also be chest pain.

Treatment. In acute cases, thoracentesis may be needed to drain the pleural cavity. For chronic atelectasis, treatment may include chest percussion, postural drainage, coughing, deep breathing exercises, and intermittent positive-pressure breathing (IPPB).

BRONCHITIS is inflammation of the bronchi and often follows a cold. Bronchitis that occurs frequently often indicates more serious underlying conditions, such as asthma or emphysema. Smokers are much more likely to develop bronchitis than are nonsmokers. Repeated episodes of bronchitis increase a person's chance of eventually developing lung cancer.

Causes. This condition can be caused by viruses and gastroesophageal reflux disease (GERD), a condition in which acids move from the stomach into the esophagus. Exposure to

cigarette smoke, pollutants, and household cleaner fumes can also contribute to the development of bronchitis.

Signs and Symptoms. The signs and symptoms include chills, fever, coughing up yellow-gray or green mucus, tightness in the chest, wheezing, and dyspnea.

Treatment. This condition can be treated with rest, fluids, nonprescription and prescription cough medicines, and the use of a humidifier. Antibiotics are usually prescribed only for smokers. Patients who also have asthma may need to use inhalers. They should also wear masks if they may be exposed to lung irritants.

CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD) is a group of lung disorders that limit airflow to the lungs and usually cause enlargement of the alveoli in the lungs. Emphysema and chronic bronchitis are the most common types of COPD.

Causes. The primary causes are smoking and air pollution.

Signs and Symptoms. Common signs and symptoms include dyspnea, hypoxia (inadequate oxygenation of the cells), fatigue, and frequent coughing.

Treatment. Treatment should first be focused on lifestyle changes, especially smoking cessation. Other treatment options include respiratory therapy and the use of inhalers. In more serious cases, a lung transplant may be necessary.

EMPHYSEMA is a chronic condition that damages the alveoli of the lungs. It is heavily associated with smoking, which causes stretching of the spaces between the alveoli and paralyzes the cilia of the respiratory system.

Causes. The most common causes are cigarette smoking and exposure to cigarette smoke; pollutants; and the dust from grains, cotton, wood, or coal.

Signs and Symptoms. Symptoms include shortness of breath that progresses over time, chronic cough, unintended weight loss, and fatigue. Pulmonary function tests and arterial blood gases become increasingly more abnormal as the disease progresses. In advanced cases, patients develop the characteristic barrel chest caused by the muscular changes in the chest as the patient struggles to breathe.

Treatment. Smoking cessation and prevention of exposure to cold environments and pollutants should be the first treatment measures. Vaccinations to prevent the flu and pneumonia as well as antibiotics to control the respiratory infections associated with emphysema may also be administered. In addition, patients can be treated with bronchodilators, supplemental oxygen, inhaled steroids, and respiratory therapy. The most serious cases may require either surgery to remove damaged lung tissue or a lung transplant, without which patients will develop respiratory and/or heart failure, resulting in death.

INFLUENZA is more commonly called the flu. Babies, the elderly, people with suppressed immune systems, and those with chronic respiratory illnesses, such as COPD, are at the highest risk of developing influenza. The flu normally lasts between 5 and 10 days.

Causes. This disease is caused by a number of different viruses that attack the respiratory system. It can be prevented or at the least the course shortened and symptoms lightened through a yearly flu vaccination. Note that each year there are multiple strains of influenza. Therefore, the vaccine available each year is for the known strains for that year. Explain this to patients so that they understand they need a flu shot each year for that year's specific strains of the virus.

Signs and Symptoms. Common symptoms include a runny nose (rhinorrhea), sore throat (pharyngitis), sneezing, fever or chills, dry cough, muscle pain, fatigue, anorexia (loss of appetite), and diarrhea.

Treatment. OTC analgesics and antipyretics can alleviate the aches and pains as well as the fever associated with the flu. Other treatment options include bed rest, fluids, and antiviral medications.

LARYNGITIS is an acute inflammation of the larynx. Chronic laryngitis is associated with lung cancer.

Causes. The causes of this condition are varied and include the following: viruses; bacteria; polyp formation in the larynx; excessive talking, shouting, or singing; allergies; smoking; frequent heartburn; the frequent use of alcohol; damage to nerves that supply the larynx; and a stroke (cerebrovascular accident, or CVA) that paralyzes vocal cord muscles.

Signs and Symptoms. Signs and symptoms include a hoarse voice (dysphonia), a sore throat (pharyngitis), a dry cough and throat, and tickling sensations in the throat.

Treatment. The most common treatment options are antibiotics, the management of heartburn, the avoidance of cigarettes and alcohol, and voice rest. The treatment of more serious cases includes the removal of laryngeal polyps and surgery to tighten the vocal cords.

LEGIONNAIRE'S DISEASE is an acute type of bacterial pneumonia. As with many respiratory diseases, smokers are much more susceptible to pneumonia than are nonsmokers.

Causes. This disease is caused by Legionnaire bacilli that usually grow in the standing water of air-conditioning systems.

Signs and Symptoms. The symptoms include fever, which may spike as high as 105.8°F, fatigue, anorexia, dyspnea, frequent coughing, chest pain, muscle aches, and headache. Complications may include hypotension, arrhythmia, respiratory and renal failure, and shock, which is often fatal.

(a) Healthy lung, mediastinal surface

(b) Smoker's lung with carcinoma

FIGURE 28-5 A healthy lung is pink, unlike a lung with cancer caused by smoking, as shown on the right.

© McGraw-Hill Education/Dennis Strete, photographer; © Biophoto Associates/Science Source

Treatment. Treatments include antibiotics, antipyretics, and respiratory therapy, including oxygen and ventilator support if needed. Supportive therapy, such as IV fluids, is also used.

LUNG CANCER kills more people in the United States than any other type of cancer. Although other causes of cancer exist, smoking and secondhand smoke account for approximately 85% of all lung cancer cases. See Figure 28-5.

Causes. The primary causes of lung cancer are smoking and exposure to radon, asbestos, and industrial carcinogens.

Signs and Symptoms. The respiratory symptoms include a cough that worsens over time, hemoptysis (coughing up blood), dyspnea, wheezing, shortness of breath, and recurrent bronchitis. Other symptoms are chest pain, dysphonia, unintended weight loss, and bone pain if the cancer has spread.

Classification. Lung cancer is classified as follows:

- **Small cell lung cancer.** This type occurs almost exclusively in smokers. It is the most aggressive type and spreads readily to other organs. Small cell lung cancer that spreads to other organs is termed *extensive*.
- **Squamous cell lung cancer.** This type of lung cancer arises from the epithelial cells that line the bronchi and bronchioles of the lungs. It occurs most commonly in men.
- **Adenocarcinoma.** This type arises from the mucus-producing cells of the lungs. It develops most commonly in women and nonsmokers.
- **Large cell carcinoma.** This type of lung cancer arises from the peripheral parts of the lungs.

Stages. Squamous cell lung cancer, adenocarcinoma, and large cell carcinoma are staged as follows:

- Stage 0: Cancer is found only in the lining of the bronchi and bronchioles of the lungs.
- Stage 1: Cancer has spread from the lining of the bronchi and bronchioles to lung tissues.
- Stage 2: Cancer has spread to the lymph nodes or the chest wall.
- Stage 3: Cancer has spread to the lymph nodes and to other organs within the chest.
- Stage 4: Cancer has spread to organs outside the chest.

Small cell lung carcinoma is staged as follows:

- Limited-stage small cell lung cancer: Cancer is found in one lung, the tissues between the lungs, and nearby lymph nodes only.
- Extensive-stage small cell lung cancer: Cancer has spread outside of the lung in which it began or to other parts of the body.

Treatment. Treatment varies, depending on the type of cancer and the stage. Stopping smoking and avoiding exposure to secondhand smoke should be the first treatment considerations. Common treatment options include chemotherapy and radiation therapy. More serious cases may require the surgical removal of tumors (if they are confined), a lobectomy (the removal of a lung lobe or lobes), or a pneumonectomy (the removal of an entire lung).

PLEURAL EFFUSION is a buildup of fluid in the pleural cavity.

Causes. Effusions are caused by either an overproduction of pleural fluid or an inadequate absorption of the fluid. These often result from an underlying disease, such as congestive heart failure, cirrhosis, tuberculosis, cancer, lupus, or rheumatoid arthritis.

Signs and Symptoms. As the fluid builds in the pleural space, the lungs begin to compress, reducing the gaseous exchange of oxygen and carbon dioxide. Infective processes may result in a pus buildup, which is known as empyema.

Treatment. **Thoracentesis** is done to remove the fluid and/or pus. **Thoracostomy**, which involves the insertion of a tube to continually drain the fluid, may be required to maintain drainage of the acute phase of the illness. Oxygen may be administered to increase oxygen concentration in the lung. Antibiotics may also be required for any infective process.

PLEURITIS, or *pleurisy*, is a condition in which the pleura becomes inflamed. This often causes the membranes to stick together or can cause an excess amount of fluid to form between the membranes.

Causes. Causes include viruses, pneumonia, autoimmune diseases such as lupus or rheumatoid arthritis, tuberculosis, a pulmonary embolism, inflammation of the pancreas, and trauma to the chest.

Signs and Symptoms. Symptoms include fever or chills; a dry cough; shortness of breath; and a sharp, stabbing chest pain during respiration.

Treatment. Analgesics may be prescribed to relieve chest pain. Anti-inflammatory drugs, antibiotics, and the removal of fluid around the lungs by thoracentesis are the primary treatment options.

PNEUMOCONIOSIS is the name given to lung diseases that result from years of exposure to different environmental or occupational types of dust. There are three basic types: *anthracosis*, *asbestosis*, and *silicosis*.

Causes. Anthracosis (black lung disease) results from exposure to coal dusts. Asbestosis results from lung exposure to asbestos. Silicosis arises from exposure to silica sand from sand blasting and ceramic manufacture.

Signs and Symptoms. These include tachypnea, nonproductive cough, progressive dyspnea on exertion, pulmonary hypertension, recurrent respiratory infections, and eventual right ventricular hypertrophy. In all cases, fibrous tissue takes over healthy lung tissue, which destroys the alveoli and takes over the air passageways.

Treatment. Treatment for all types includes avoiding respiratory infections, using bronchodilators, and using supplemental oxygen as needed. Respiratory therapy can also be useful in helping patients rid themselves of respiratory secretions.

PNEUMONIA, also known as *pneumonitis*, is characterized by an inflammation of the lungs caused by a bacterial, viral, or fungal infection. There are at least 50 different types of pneumonia, and they range from mild to serious. *Double pneumonia* refers to inflammation of both lungs.

Causes. Pneumonia can be caused by bacteria, viruses, fungi, and parasites. It can also be caused by foreign matter that enters the lungs (for example, stomach contents that enter the lungs after vomiting), known as aspiration pneumonia. This disorder may be prevented by not smoking and, for some types of pneumonia, by pneumococcal vaccinations.

Signs and Symptoms. Common signs and symptoms include fever or chills, headache, chest or muscle pain, fatigue, dyspnea, and sputum consisting of rust-colored, green, or yellowish mucus.

Treatment. Rest, fluids, OTC pain medications, and antibiotics are the most common treatments. In severe cases, oxygen and ventilator support may be required.

PNEUMOTHORAX is a collection of air in the chest around the lungs, which may cause atelectasis.

Causes. Some causes of this disorder are unknown. Various respiratory diseases and trauma to the chest, such as a stabbing wound, can also contribute to the development of pneumothorax.

Signs and Symptoms. The primary symptoms include tightness in the chest or a sharp chest pain, shortness of breath, and a rapid heart rate.

Treatment. The insertion of a chest tube (thoracostomy) to remove air from the chest and surgery to repair chest wounds are the primary treatments.

PULMONARY EDEMA is a condition in which fluids fill spaces within the lungs. This disorder makes it very difficult for the lungs to oxygenate the blood. It most commonly occurs when the heart cannot pump all the blood it receives from the lungs. Left heart failure occurs when blood then backs up in the lungs, causing fluids to seep into lung spaces.

Causes. The many causes of this condition include the following: congestive heart failure, myocardial infarction (heart attack), cardiomyopathy, heart valve disorders, lung infections, allergic reactions, smoke inhalation, drowning, various drugs such as narcotics and heroin, chest injuries, and high altitudes. This disorder may be prevented by avoiding high altitudes and smoking. Preventing heart disease may also reduce the chance of developing this disorder.

Signs and Symptoms. The symptoms of pulmonary edema are shortness of breath; difficulty breathing, especially when lying down (a condition known as *orthopnea*); a feeling of suffocating; wheezing; a productive cough that produces pink mucus; rapid weight gain; pallor; and profuse sweating, which is known as diaphoresis.

Treatment. Treatment includes oxygen therapy, diuretics to eliminate excess fluids, and morphine to reduce anxiety and shortness of breath.

PULMONARY EMBOLISM is a blocked artery in the lungs. Usually the artery is blocked by a blood clot that has traveled from a vein in the legs. If an artery in the lungs is completely blocked, death can occur quickly from resultant respiratory failure.

Causes. People at the highest risk of developing this condition are those who have had previous heart attacks, cancer, a fractured hip, or chronic lung diseases. Women who use birth control pills and individuals who have a pacemaker may be at risk for developing a pulmonary embolism. In addition, long periods of inactivity, increased levels of clotting factors in the blood (usually caused by certain cancers), injury to veins, or a stroke that causes paralysis of the arms or legs may cause this condition. A sedentary lifestyle as well as auto or airplane travel—or any activity that requires prolonged sitting or standing—are also major risk factors for developing a pulmonary embolism. A half-dose aspirin (formerly known as a baby aspirin) taken daily, as well as plenty of fluids and frequent movement of the arms and legs, may help prevent the development of a pulmonary embolism.

Signs and Symptoms. Symptoms include fainting, a sudden shortness of breath, hemoptysis (coughing up blood), wheezing, tachycardia (a rapid heartbeat), diaphoresis (profuse sweating), and chest pain that may spread to a shoulder, an arm, or the face.

Treatment. Support stockings can be used to promote circulation. The patient should rest until the blood clot has dissolved and may be prescribed thrombolytic (clot-dissolving) medications, such as TPA. Anticoagulants, typically warfarin, may be used to prevent new blood clots from forming in the deep veins of the body. Finally, a filter may be surgically implanted in the vena cava to prevent blood clots from reaching the lungs.

RESPIRATORY DISTRESS SYNDROME (RDS), which was formerly known as hyaline membrane disease, kills apparently healthy infants. At highest risk are newborns to infants 8 months of age, especially “preemies.”

Causes. The etiology is unknown. The underlying problem is known to be a lack of surfactant in the lungs. Surfactant helps prevent the alveoli from totally collapsing on expiration. Without it, the alveoli collapse, resulting in poor oxygenation due to difficulty with reinflation of the alveoli.

Signs and Symptoms. RDS is usually diagnosed soon after birth, when the infant’s breathing becomes rapid and shallow. The infant’s nares flare, and the accessory muscles are used to aid in respiration. The infant will also exhibit “grunting” noises in an attempt to breathe.

Treatment. Treatment must be immediate, preferably in a neonatal intensive care unit (NICU). Oxygen therapy, an endotracheal tube, ventilator support, and artificial surfactant are all used in an attempt to keep the alveoli inflated. Infants who survive RDS may be at higher risk for respiratory infections later, but this threat lessens as their lungs continue to mature.

SEVERE ACUTE RESPIRATORY SYNDROME (SARS) is a respiratory disease that is very contagious and sometimes fatal. It was first identified in 2003.

Causes. SARS is caused by viruses associated with the common cold as well as by unknown viruses. It can be prevented by

thoroughly washing the hands, wearing a mask, and avoiding exposure to individuals with this disease.

Signs and Symptoms. Signs and symptoms include fever or chills, headache, a dry cough, and muscle aches.

Treatment. Rest and antiviral drugs are the primary treatments.

SINUSITIS is an inflammation of the membranes lining the sinuses of the skull.

Causes. Bacteria, excess mucus production in the sinuses (often from the “common cold”), the blockage of sinus openings, and the destruction of cilia that move mucus out of sinuses can cause this disorder.

Signs and Symptoms. Fever, cough, headache, pharyngitis, facial pain, and nasal congestion are the common signs and symptoms.

Treatment. Treatment options include the use of nasal decongestants, nasal steroid sprays, a humidifier, applications of heat to the face, and antibiotics. Surgery to clear the sinuses or unblock sinus openings may be required.

SUDDEN INFANT DEATH SYNDROME (SIDS) claims the life of more than 7,000 babies a year in the United States. There are no characteristic signs or symptoms. Usually a baby with this disorder simply goes to sleep and never wakes up.

Causes. The causes of SIDS are unknown, but certain risk factors have been identified:

- Male babies are more likely to die of SIDS.
- Babies are most susceptible between the ages of 2 weeks and 6 months.
- Premature or low birth weight babies are more likely to have SIDS.
- A baby with a sibling who died of SIDS is more likely to also die of this disorder.
- African American or Native American babies are more likely to die of SIDS.
- Babies who were prenatally exposed to alcohol, cocaine, heroin, or nicotine are at a higher risk of developing SIDS.
- Babies who sleep on their stomachs are approximately three times more likely to die of SIDS.

Treatment. Proper sleep positioning on the baby’s back is best for all infants, especially those known to be at risk, those with previous apneic episodes, and those who have lost a sibling to SIDS. At-risk infants may also be sent home with an apnea monitor that will sound an alarm if breathing ceases. Research into this disease is ongoing. Support groups are available and are suggested for families who have experienced the tragedy of losing a child to SIDS.

TUBERCULOSIS (TB) kills more than 2 million people worldwide each year. Although it primarily affects the lungs, it can spread to other parts of the body.

Causes. This disease is caused by various strains of the bacterium *Mycobacterium tuberculosis*. Widespread tuberculosis may be complicated by the following factors:

- HIV infection. HIV infection makes a person more vulnerable to TB.
- Crowded living conditions. This factor allows TB to spread easily; TB, therefore, is found in some prisons and homeless shelters.
- Poverty. Poverty prevents some patients with TB from seeking or completing therapy.
- Drug-resistant bacterium. Drug-resistant strains of the bacterium that causes TB have increased.
- Long-term therapy. Current treatments require antibiotic therapy for many months, which some patients with TB do not complete.

Signs and Symptoms. The symptoms include a cough that lasts more than 3 weeks, unintended weight loss, fever or chills, fatigue, night sweats, pain when breathing or difficulty breathing, and pain in other affected areas.

Treatment. The first step should be TB testing to detect carriers of this disease, who should then be treated. Therapy for TB normally lasts 6 months to a year, but drug-resistant cases of TB may require years of drug therapy. Isolating the patient during

the contagious phase of the disease (usually 2 to 4 weeks after treatment begins) is required. Also, during the initial stages of treatment, the patient should be encouraged to receive adequate bed rest and maintain an adequate, nutritious diet.

UPPER RESPIRATORY (TRACT) INFECTION (URI) is the term often used for *coryza*, or the common cold.

Causes. URIs are caused by a family of viruses known as *rhinovirus*. The viruses are airborne and transmitted by contact with contaminated surfaces and on the hands. Children are frequent sources of transmission.

Signs and Symptoms. This is a generally self-limiting condition of approximately 1 week’s duration, which follows an initial incubation period of 2 to 5 days. Symptoms include pharyngitis, nasal congestion, rhinitis, headache, fever, and general malaise. There may be a nonproductive cough, especially at night.

Treatment. Care is usually symptomatic and includes antipyretics, analgesics, decongestants, and cough suppressants. Adequate rest and plenty of fluids to flush the system are also helpful. Antibiotics are ordinarily only prescribed for patients with an underlying illness or complication.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
28.1 Describe the structure and function of each organ in the respiratory system.	The function of the respiratory system is to move air into and out of the lungs in a process known as ventilation, respiration, or breathing. The larynx contains the vocal cords, which stretch between the thyroid and cricoid cartilages. The lungs contain connective tissue, the bronchial tree, nerves, lymphatic vessels, and blood vessels. The bronchial tree consists of the primary, secondary, and tertiary branches of the bronchi, the bronchioles, and the alveoli.
28.2 Describe the events involved in the inspiration and expiration of air.	During inspiration, the diaphragm contracts and the intercostal muscles raise the ribs, increasing the space in the thoracic cavity. This decreases the pressure within the cavity so that the air outside the body passively flows into the thoracic cavity. During expiration, the diaphragm relaxes, pushing up into the thoracic cavity, and the intercostal muscles lower the ribs, forcing the air to flow out of the body. Breathing is controlled by the respiratory center of the brain, located in the pons and medulla oblongata.
28.3 Explain how oxygen and carbon dioxide are transported in the blood.	Most of the oxygen in the bloodstream binds to the hemoglobin within red blood cells, resulting in oxyhemoglobin, although a small amount does not bind to hemoglobin and remains dissolved in the plasma. Carbon dioxide binds to hemoglobin, resulting in carboxyhemoglobin. Most of the carbon dioxide that enters the blood reacts with water in plasma and cerebrospinal fluid to form carbonic acid. As carbonic acid ionizes, it releases hydrogen and bicarbonate ions, which attach to hemoglobin making its way back to the lungs to be exhaled.

LEARNING OUTCOMES	KEY POINTS
28.4 Compare various respiratory volumes and tell how they are used to diagnose respiratory problems.	Respiratory volumes are measured to check the health of the respiratory system. The volumes are tidal volume, inspiratory and expiratory reserve volumes, residual volume, inspiratory capacity, functional residual capacity, vital capacity, and total lung capacity. The normal capacities are found in the chapter.
28.5 Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the respiratory system.	There are many common diseases and disorders of the respiratory system with varied signs, symptoms, and treatments. Some of these include allergic rhinitis, asthma, atelectasis, bronchitis, chronic obstructive pulmonary disease (COPD), emphysema, influenza, laryngitis, Legionnaire's disease, lung cancer, pleural effusion, pleuritis, pneumoconiosis, pneumonia, pneumothorax, pulmonary edema, pulmonary embolism, respiratory distress syndrome (RDS), severe acute respiratory syndrome (SARS), sinusitis, sudden infant death syndrome (SIDS), tuberculosis (TB), and upper respiratory (tract) infection (URI).

CASE STUDY CRITICAL THINKING

© David Sacks/Getty Images

Recall Mohammad from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. Why is asthma considered a life-threatening condition?

2. Why did the doctor refer Mohammad for allergy testing?

3. In addition to the prescribed medication, what can Mohammad do to help reduce his symptoms?

EXAM PREPARATION QUESTIONS

- (LO 28.1) Which of the following is/are known as the pulmonary parenchyma?
 - Nares
 - Bronchi
 - Bronchioles
 - Alveoli
 - Larynx
- (LO 28.2) What is responsible for raising and lowering the rib cage during respiration?
 - Diaphragm
 - Lungs
 - Intercostal muscles
 - Respiratory center
 - Spinal cord
- (LO 28.5) Lack of surfactant is responsible for which of the following in premature infants?
 - SARS
 - RDS
 - COPD
 - Pneumonia
 - Asthma
- (LO 28.1) Which structure covers the larynx during swallowing?
 - Epiglottis
 - Glottis
 - Conchae
 - Hyoid
 - Uvula

5. (LO 28.5) Which condition is commonly known as a collapsed lung?
 - a. Bronchitis
 - b. Pleuritis
 - c. Coryza
 - d. Pneumonia
 - e. Atelectasis
6. (LO 28.3) Most of the carbon dioxide in the blood remains in the plasma in which of the following forms?
 - a. Carboxyhemoglobin
 - b. Carbon monoxide
 - c. Bicarbonate
 - d. Carbonic acid
 - e. Oxyhemoglobin
7. (LO 28.4) Which term refers to the total amount of air the lungs can hold?
 - a. Total lung capacity
 - b. Vital capacity
 - c. Tidal volume
 - d. Expiratory reserve volume
 - e. Inspiratory reserve volume
8. (LO 28.2) Which of the following everyday occurrences alters our breathing patterns?
 - a. Blinking
 - b. Swallowing
 - c. Yawning
 - d. Watching TV
 - e. Studying
9. (LO 28.5) The most common types of COPD are emphysema and which other disorder?
 - a. Pleuritis
 - b. Chronic bronchitis
 - c. Asthma
 - d. Pleural effusion
 - e. Legionnaire's disease
10. (LO 28.2) Which of the following occurs during expiration?
 - a. Air flows into the lungs
 - b. The diaphragm contracts
 - c. The diaphragm flattens
 - d. The thoracic cavity enlarges
 - e. The intercostal muscles lower the ribs

The Nervous System

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Nancy Evans	1/29/19XX	Amoxicillin
	Attending	MRN	Other Information
	Elizabeth H. Williams, MD	654-88-099	PET scan: Minor restrictions of blood flow in some areas MRI: WNL Lumbar puncture: WNL FH: Negative for Alzheimer's disease

In preparing for the patient interview, you check the chart and notice that at Nancy's previous visit, the physician ordered an MRI, a PET scan, and a lumbar puncture. She is here for a follow-up visit to find out the results of these tests. During the patient interview, you ask the patient her name and date of birth. She states, "I am Nancy Evans, I am Welsh, and I was born in January but I don't remember

© John Lund/Sam Diephuis/Blend Images LLC RF

what year." You look at the chart and note that her name is Nancy Evans and she was born on January 29, 1945. Her husband is in the waiting room; after obtaining Nancy's permission, you ask him to come to the interview area. He confirms Nancy's complete name and date of birth and then states, "She seems to forget every-

thing these days. I sure hope these tests last week will help you find out what is causing it."

Keep Nancy in mind as you study the chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

LEARNING OUTCOMES

After completing Chapter 29, you will be able to:

- 29.1** Describe the general functions of the nervous system.
- 29.2** Summarize the structure of a neuron.
- 29.3** Explain the function of nerve impulses and the role of synapses in their transmission.
- 29.4** Describe the structures and functions of the central nervous system.
- 29.5** Compare the structures and functions of the somatic and autonomic nervous systems in the peripheral nervous system.
- 29.6** Recognize common tests that are performed to determine neurologic disorders.
- 29.7** Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the nervous system.

KEY TERMS

- | | |
|------------------------------|---------------------------------|
| afferent nerves | myelin sheath |
| autonomic nervous system | neuroglia |
| axon | neurotransmitter |
| cell body | parasympathetic branch |
| central nervous system (CNS) | paresthesia |
| cerebrospinal fluid (CSF) | peripheral nervous system (PNS) |
| dendrite | plexus |
| dermatome | Schwann cells |
| efferent nerves | somatic nervous system |
| ganglia | sympathetic branch |
| interneurons | synaptic knob |
| meninges | |

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.6** Compare structure and function of the human body across the life span
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each system

3. Medical Terminology

- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

► Introduction

The nervous system is highly complex. It controls all other organ systems and is important for maintaining balance within those systems. Disorders of the nervous system are often difficult to diagnose and treat because of this system's complexity.

► General Functions of the Nervous System

LO 29.1

The nervous system is divided into two major parts—the **central nervous system (CNS)** and the **peripheral nervous system (PNS)**. The CNS consists of the brain and the spinal cord; the peripheral nervous system consists of peripheral nerves, which are located throughout the rest of the body.

The peripheral nervous system is further divided into two separate sections: the **somatic nervous system**, which governs your body's skeletal (or voluntary) muscles, and the **autonomic nervous system**, which is in charge of your body's automatic functions, such as breathing and digesting food.

Three different types of nerve cells carry out the functions of the nervous system:

- **Afferent nerves**—sensory nerves responsible for detecting information from the environment or from inside the body and taking it to the CNS for interpretation
- **Efferent nerves**—motor nerves that take information or impulses from the CNS to the PNS to control the movement or action of a muscle or gland
- **Interneurons**—neurons in the brain and spinal cord that lie between the sensory and motor nerves and act as

go-betweens, or interpreters, between the afferent and efferent nerves

An example of how the nervous system works would be noting a red light while driving. The afferent (sensory) neurons in your eyes note the color and send the information to the brain's cerebral cortex, where the interpretation takes place. The interneurons pick up the signal, interpret it, and send the information to the efferent (motor) neurons that you are supposed to stop your vehicle, which in turn sends the instructions to your right foot to step on the brake pedal of your vehicle. This entire transaction, of course, takes place in milliseconds, allowing you to stop in time.

The nervous system also includes a type of cell called *neuroglial cells*, or **neuroglia**. These cells do not transmit impulses. Instead, they function as support cells for neurons. (See Figure 29-1.) Neuroglial cells never lose their ability to divide. The three types of neuroglia are

- *Astrocytes*—star-shaped cells that anchor blood vessels to the nerve cells.
- *Microglia*—small cells that detect, engulf, and destroy invaders.
- *Oligodendrocytes*—cells that assist in the production of the myelin sheath, which will be discussed in further detail later.

► Neuron Structure

LO 29.2

Neurons are the functional cells of the nervous system. They transmit electrochemical messages called *nerve impulses* to other neurons and *effectors* (muscles or glands). An important

FIGURE 29-1 A typical neuron surrounded by neuroglial cells.

© Allen Bell/Corbis RF

characteristic of neurons is that they lose their ability to divide. Therefore, when neurons are destroyed by disease, they cannot be replaced.

All neurons have a **cell body** and nerve fibers that extend from the cell body. The cell body is the portion of the neuron that contains the nucleus and the organelles typical of any cell. (Refer to the *Organization of the Body* chapter.) It is responsible for generating the large amount of protein and energy the neuron needs to carry out its functions.

Extending from the cell body are two types of nerve fibers: **axons** and **dendrites**. A neuron may have one or more dendrites but typically has only one axon. Dendrites are usually short and branch profusely near the cell body. Their function is to receive information for the neuron. Axons are typically long and branch profusely after they have extended far away from the cell body. Their function is to send information (nerve impulses) away from the cell body.

In the PNS, cells called **Schwann cells** wrap themselves around the axons of some of the neurons (see Figure 29-2). Schwann cells contain a large amount of myelin, a fatty substance that insulates the axons. This insulation, called a **myelin sheath**, allows nerve impulses to move more quickly through the axons.

► Nerve Impulse and Synapse LO 29.3

Neuron cell membranes have a *cell membrane potential*. This means the membrane is *polarized*. Just as a battery is polarized—one end is negative and the other end is positive—neuron cell membranes are polarized, because the inside is negatively charged and the outside is positively charged. This is true in most other types of body cells as well. The outside of cell membranes is positively charged because more positive ions are on the outside. The inside of cell membranes is negatively charged because more negative ions are on the inside. This membrane potential is very important for the function of neurons (see Figure 29-3).

FIGURE 29-2 Schwann cells wrap around the axons of some neurons to create an insulating sheath that speeds up impulse transmission.

Potassium and sodium ions are both positively charged and play important roles in generating nerve impulses. When a neuron is at rest or without stimulation, the outside of its membrane is relatively positive and the inside is relatively negative because the number of sodium and potassium ions is greater outside the membrane. As long as the neuron is at rest, it remains in this polarized state.

When a neuron detects a stimulus, such as heat or pressure, some of the sodium ions on the outside of the membrane move inside. This changes the polarization of the cell membrane, making the outside less positive and the inside more positive. There is now less difference between the inside and outside of the membrane, so it is said to be *depolarized*. The depolarization creates a nerve impulse, or electric current. The nerve impulse moves along the length of the axon as small areas along the axon become depolarized and then almost immediately repolarize, as shown in Figure 29-4. Repolarization begins when potassium moves outside the membrane, followed by sodium. Eventually, the potassium moves back inside the membrane and the cell is once again polarized (see Figure 29-3).

The speed of a nerve impulse depends on several factors. Myelinated axons conduct impulses faster than those that do not have a myelin sheath. The diameter of the axon also affects the speed of transmission. The larger the diameter, the faster the nerve impulse travels through the axon.

When traveling down an axon, a nerve impulse eventually reaches the **synaptic knob** at the end of the axon branches. Synaptic knobs contain small sacs called *vesicles* that produce chemicals called **neurotransmitters**. Neurotransmitters are released by the synaptic knob to transport the nerve impulse from the end of the axon to the dendrites of other neurons (see Figure 29-5). This allows the impulse to be conducted along a chain of neurons to reach its destination.

There are about 50 different neurotransmitters. In addition to helping transmit nerve impulses, many neurotransmitters perform other functions. These include causing muscles to contract or relax, causing glands to secrete products, activating

(a)

(b)

Region of repolarization

(c)

FIGURE 29-3 Nerve impulse: (a) At rest, or in its polarized state, more sodium (Na^+) is on the outside of the membrane, which makes the outside positive and the inside relatively negative (less positive). (b) When Na^+ moves into the cell, the membrane depolarizes, and the inside becomes more positive. (c) The membrane repolarizes when potassium (K^+) and later Na^+ move to the outside of the cell membrane.

neurons to send nerve impulses, and inhibiting neurons from sending nerve impulses.

Central Nervous System

LO 29.4

The CNS includes the spinal cord and brain (see Figure 29-6). The tissues of the CNS are so delicate that a *blood-brain barrier* and layers of membranes protect them. Tight capillaries form the blood-brain barrier, which prevents certain substances from entering the tissues of the CNS. For example, various waste products and drugs do not cross the blood-brain barrier well. Inflammation, however, can make this barrier more permeable.

Meninges are membranes that protect the brain and spinal cord. The three layers of meninges are *dura mater*, *arachnoid mater*, and *pia mater*. *Dura mater* is the toughest and outermost layer of the meninges. The space above the *dura mater* is called the *epidural space*; below the *dura mater* is the *subdural space*. The middle layer, named for its spider

(a)

(b)

(c)

web-like appearance, is the *arachnoid mater*. *Pia mater* is the innermost and most delicate layer. It sits directly on top of the brain and spinal cord and holds blood vessels onto the surface of these structures. Between the *arachnoid mater* and *pia mater* is an area called the *subarachnoid space*. It contains **cerebrospinal fluid (CSF)**, sometimes referred to simply as *spinal fluid*, which cushions the CNS.

Spinal Cord

The spinal cord is a slender structure that is continuous with the brain. The spinal cord descends into the vertebral canal and ends around the level of the first or second lumbar vertebra. The spinal cord is divided into 31 spinal segments: 8 cervical segments, 12 thoracic segments, 5 lumbar segments, 5 sacral segments, and 1 coccygeal segment. The thickening of the spinal cord in the neck region is called the *cervical enlargement* and contains the motor neurons that control the arm muscles. Another thickening of the spinal cord occurs in the lumbar region. Called the *lumbar enlargement*, this thickening contains the motor neurons that control the leg muscles (see Figure 29-6).

Gray Matter and White Matter When you view a cross section of the spinal cord, you observe two differently

FIGURE 29-5 Synapse. When a nerve impulse reaches a synaptic knob, it releases a neurotransmitter that transports the impulse to the dendrites of the next neuron.

colored areas (see Figure 29-7). The inner tissue is termed *gray matter* because it is darker than the outer tissue, which is termed *white matter*. The white matter contains the myelinated axons of neurons. It is divided into columns that contain groups of axons called *nerve tracts*. The gray matter contains the neuron cell bodies and dendrites, as well as unmyelinated axons. A canal called the *central canal* contains CSF and runs through the center of the gray matter down the entire length of the spinal cord.

Ascending and Descending Tracts One function of the spinal cord is to carry sensory information up to the brain. The tracts that carry sensory information up to the brain are called *ascending tracts*. Another function of the spinal cord is to carry motor information down from the brain to muscles and glands in tracts called *descending tracts*.

Reflexes Another important function of the spinal cord is to provide reflexes. A *reflex* is a predictable, automatic response to a stimulus. For example, if you touch something hot, the predictable response is that you will pull your finger away from the hot surface in a withdrawal reflex. The information that flows through a typical reflex moves in the following order: from receptors to sensory neurons to interneurons to motor neurons to effectors. Figure 29-8 shows what happens in a typical reflex action. When a person steps on a tack, the receptors at the ends of the sensory neurons generate a nerve

FIGURE 29-6 The central nervous system (CNS) consists of the brain and spinal cord. The spinal cord ends at the level of the third lumbar vertebra.

impulse that travels through the sensory neurons directly to the interneurons in the spinal cord. The interneurons interpret the impulse and determine which muscles must be activated to remove the foot from the tack. They immediately trigger the motor neurons to act, inhibiting some muscle movements and stimulating others and coordinating the muscle movements to move the foot away from the painful stimulus.

FIGURE 29-7 A cross section of the spinal cord shows the gray matter and the white matter that surrounds it. The central canal is located at the center of the spinal cord, in the gray matter.

FIGURE 29-8 The cross section of the spinal cord and a spinal nerve illustrates a reflex arc.

Brain

The brain is divided into four major parts: the cerebrum, the diencephalon, the brainstem, and the cerebellum (see Figure 29-9).

Cerebrum The cerebrum is the largest part of the brain. It is divided into two halves called *cerebral hemispheres*. A thick bundle of nerve fibers called the *corpus callosum* connects the two hemispheres. The grooves on the surface of the cerebrum are called *sulci*. The “bumps” of brain matter between the sulci are called *gyri*, or convolutions. A deep groove called the *longitudinal fissure* runs between the two longitudinal hemispheres.

Lobes Each cerebral hemisphere is divided into *lobes*—frontal, parietal, temporal, and occipital. The right and left frontal lobes contain motor areas that allow a person to consciously decide to produce a body movement such as walking or tapping a pencil. Somatosensory areas are located in the parietal lobes. These areas interpret sensations felt on or within the body. For example, if you feel a light touch on your right hand, the somatosensory area interprets the sensation and where it is occurring. The temporal lobes contain auditory areas that interpret sounds. Visual areas are located in the occipital lobes, and they interpret what a person sees.

Cortex The outermost layer of the cerebrum is called the *cerebral cortex*. It is composed of gray matter and therefore

contains neuron cell bodies and dendrites. This layer contains nearly 75% of all neurons in the entire nervous system. Beneath the cerebral cortex is white matter. Besides interpreting sensory information and initiating body movements, the cortex also stores memories and creates emotions.

Ventricles The *ventricles* are the cavities in the brain that produce cerebrospinal fluid (CSF). The two lateral ventricles are the largest and are located in the cerebrum (see Figure 29-10). The third ventricle is located in the diencephalon, and the fourth ventricle is located in the brainstem. All four ventricles are responsible for producing and circulating CSF to cushion and protect the brain and spinal cord. CSF also delivers nutrients to the brain and carries away wastes.

Diencephalon The *diencephalon* is located between the cerebral hemispheres and is superior to the brainstem. The diencephalon includes the thalamus and hypothalamus. The *thalamus* serves as a relay station for sensory information that heads to the cerebral cortex for interpretation. If sensory information does not pass through the thalamus before it reaches the cerebral cortex, it cannot be interpreted correctly. For example, say you are feeling pain in your left forearm. This information goes up the spinal cord and through the thalamus, and then to the cerebral cortex for interpretation. If the information did not go through the thalamus, the cerebral cortex might interpret that you are feeling cold instead of pain in your left forearm. The *hypothalamus* maintains homeostasis by

FIGURE 29-9 Four views of the brain: (a) superior, (b) inferior, (c) left lateral, and (d) sagittal section.

regulating hunger, thirst, and body temperature. It also provides a link between the nervous system and the endocrine system.

Brainstem The *brainstem* is a structure that connects the cerebrum to the spinal cord. The three parts of the brainstem are the midbrain, the pons, and the medulla oblongata. The *midbrain* lies just beneath the diencephalon. It controls both visual and auditory reflexes. Seeing something in your peripheral vision and automatically turning your head to view it more clearly is an example of a visual reflex.

The *pons* is a rounded bulge on the underside of the brainstem between the midbrain and the medulla oblongata. It contains nerve tracts to connect the cerebrum to the cerebellum. The pons also regulates respiration.

The *medulla oblongata* is the most inferior portion of the brainstem and is directly connected to the spinal cord. It

controls many vital activities such as heart rate, blood pressure, and respiration. It also controls reflexes associated with coughing, sneezing, and vomiting.

Cerebellum The cerebellum is inferior to the occipital lobes of the cerebrum and posterior to the pons and medulla oblongata. It coordinates the complex skeletal muscle contractions needed for body movements. For example, when you walk, many muscles have to contract and relax at appropriate times. Your cerebellum coordinates these activities. The cerebellum also coordinates fine movements such as threading a needle, playing an instrument, and writing.

Maintaining the health of the central nervous system is vital. See the feature *Educating the Patient* for more information on preventing brain and spinal cord injuries.

FIGURE 29-10 The CSF produced in the ventricles cushions and protects the brain and spinal cord.

► Peripheral Nervous System

LO 29.5

The peripheral nervous system (PNS) consists of nerves that branch off the CNS. These *peripheral nerves* are classified into two types: cranial nerves and spinal nerves.

Cranial Nerves

Cranial nerves are peripheral nerves that originate from the brain. The 12 cranial nerves are identified using Roman numerals as well as descriptive names (see Figure 29-11):

- I. *Olfactory nerves* carry smell information to the brain for interpretation.
- II. *Optic nerves* carry visual information to the brain for interpretation.
- III. *Oculomotor nerves* are found in the muscles that move the eyeball, eyelid, and iris.
- IV. *Trochlear nerves* act in the muscles that move the eyeball.
- V. *Trigeminal nerves* carry sensory information from the surface of the eye, the scalp, facial skin, the lining of the gums, and the palate to the brain for interpretation. They also are found in the muscles needed for chewing.
- VI. *Abducens nerves* act in the muscles that move the eyeball.
- VII. *Facial nerves* are found in the muscles of facial expression as well as in the salivary and tear glands. These nerves also carry sensory information from the tongue.
- VIII. *Vestibulocochlear nerves* carry hearing and equilibrium information from the inner ear to the brain for interpretation.
- IX. *Glossopharyngeal nerves* carry sensory information from the throat and tongue to the brain for interpretation. They also act in the muscles of the throat.

EDUCATING THE PATIENT

Preventing Brain and Spinal Cord Injuries

In the United States alone, almost half a million people a year suffer brain and spinal cord injuries. The most common causes of these injuries are motor vehicle accidents, sports and recreational accidents—especially diving—and violence. People at the highest risk for spinal cord injuries are children and teens. However, most brain and spinal cord injuries can be prevented. Use the following tips to educate patients on preventing these types of injuries.

Prevention Tips

- Buy and use approved head gear or a helmet when riding a bike or motorcycle, or doing any sporting activity in which you might fall such as horse riding or skateboarding. Your risk of brain injury is 85% greater during a biking accident if you are not wearing a helmet. Make sure your helmet fits properly. Replace your helmet if you have hit your head while wearing it; the helmet may be compromised from the fall and thus unsafe.
- Know the depth of water into which you are diving. More than 90% of diving injuries occur in 5 feet of water or less.
- Explore diving areas before diving. For example, know where rocks are located before you dive.
- Do not drive or do any recreational activity while under the influence of alcohol or drugs. Both affect good judgment and control. Alcohol-related traffic crashes are the leading cause of disabling brain and spinal cord injuries.
- Always wear appropriate protective gear while playing any sport.
- Always wear your safety belt in the car.
- Make sure children use car seats appropriate for their age and weight.
- Be familiar with ways to get help quickly in emergencies.
- Follow traffic rules and signs while walking, biking, or driving.
- Follow safety rules posted on playgrounds, swimming pools, public beaches, and parks.
- Store firearms and ammunition in separate and locked places.
- Teach children the safety rules to follow if they find a gun.

Go to CONNECT to see an animation exercise about *Spinal Cord Injury*.

FIGURE 29-11 A view of the inferior surface of the brain shows the 12 pairs of cranial nerves.

© McGraw-Hill Education/Rebecca Gray, photographer/Don Kincaid, dissections

- X. *Vagus nerves* carry sensory information from the thoracic and abdominal organs to the brain for interpretation. These nerves are also found in the muscles in the throat, stomach, intestines, and heart.
- XI. *Accessory nerves* are found in the muscles of the throat, neck, back, and larynx.
- XII. *Hypoglossal nerves* are found in the muscles of the tongue.

Spinal Nerves

Spinal nerves are peripheral nerves that originate from the spinal cord (see Figure 29-12). There are 31 pairs of spinal nerves: 8 pairs of cervical nerves (numbered C1 through C8), 12 pairs of thoracic nerves (numbered T1 through T12), 5 pairs of lumbar nerves (numbered L1 through L5), 5 pairs of sacral nerves (numbered S1 through S5), and 1 pair of coccygeal nerves (Cx). Except for C1, each spinal nerve innervates a skin segment known as a **dermatome**. A map of the dermatomes with the spinal nerve responsible for the skin area is shown in Figure 29-13.

The spinal nerves are formed from two roots, or nerve fibers. The ventral, or anterior, root consists of efferent (motor) nerve fibers. The dorsal, or posterior, root consists of afferent (sensory) nerve fibers. Because these two roots combine to form the spinal nerves, these nerves can carry both sensory and motor information.

Except in the thoracic region, the main portions of spinal nerves fuse together to form complex networks called **nerve plexuses**. The major nerve plexuses are the cervical, brachial, and lumbosacral plexuses. Nerves coming off the cervical plexus supply the skin and the muscles of the neck. The phrenic nerve also originates from the cervical plexus. This nerve controls the diaphragm, which is a muscle needed for breathing.

The brachial plexus includes nerves that control muscles in the arms. The lumbosacral plexus supplies the lower abdominal wall, external genitalia, buttocks, thighs, legs, and feet. The largest nerve of the body, the sciatic nerve, originates from this plexus. This nerve controls the leg muscles. The coccygeal plexus is the source of the anococcygeal nerve, which controls the muscles in the anus and the back of the thighs.

FIGURE 29-12 Spinal cord, spinal nerves, and plexuses.

Somatic and Autonomic Nervous Systems

The peripheral nervous system contains two subparts: the somatic nervous system (SNS) and the autonomic nervous system (ANS). The somatic nervous system consists of nerves that connect the central nervous system (CNS) to skin and skeletal muscle. Because it controls the skeletal muscles, which are under a person's direct (voluntary) control, this system is sometimes called the "voluntary" nervous system. The autonomic nervous system connects the central nervous system to body organs such as the heart, stomach, intestines, and bladder, as well as glands and blood vessels. Because these organs are not under a person's voluntary (direct) control, the autonomic nervous system is sometimes referred to as the "involuntary" nervous system.

In the autonomic nervous system, motor neurons from the brain and spinal cord communicate to other motor neurons located in ganglia. **Ganglia** are collections of neuron cell bodies outside the CNS. The motor neurons of ganglia then communicate to various organs and blood vessels.

The autonomic nervous system is further divided into the sympathetic and parasympathetic branches (see Figure 29-14). The **sympathetic branch** responds to stressful or emergency situations by increasing the heart rate. This is often called the "fight-or-flight" response because it increases blood flow throughout the body in preparation for immediate action. Most sympathetic neurons release the neurotransmitter norepinephrine into organs and glands. Norepinephrine increases heart and breathing rates; slows down the activity of the digestive glands, stomach muscles, and intestines; and dilates the pupils. It also constricts the blood vessels, increasing the blood pressure, which is a needed response during an emergency situation.

The **parasympathetic branch** of the autonomic nervous system does just the opposite. It keeps the heart rate relatively low, preparing the body for resting and digesting nutrients. Most of the body's organs are under parasympathetic control. All parasympathetic neurons release the neurotransmitter acetylcholine to organs and glands. Acetylcholine has

FIGURE 29-13 Dermatome maps. A dermatome is an area of skin supplied by a single spinal nerve. These diagrams only approximate the dermatomal distribution.

the opposite effect from norepinephrine. It slows the heart and breathing rates; activates the digestive glands, stomach muscles, and intestines; and constricts the pupils. It has little effect on the blood vessels, however, because most blood vessels do not receive input from the parasympathetic nerves.

► Neurologic Testing

LO 29.6

Patients with nervous system disorders may have a wide variety of signs and symptoms, but the most common are headache, muscle weakness, and **paresthesia** (loss of feeling). A typical neurologic examination can determine the following:

- **State of consciousness.** This state can vary from normal to a state of coma. A patient in a coma cannot respond to stimuli and cannot be awakened. Other terms used to describe states of consciousness include *stupor* (difficulty being awakened), *delirium* (loss of function of the cerebral cortex), *vegetative* (having no cortical function), and *asleep* (can be aroused with normal stimulation).
- **Reflex activity.** Reflex tests primarily determine the health of the peripheral nervous system.

- **Speech patterns.** Abnormal speech patterns include a loss of the ability to form words correctly or to form sentences that make sense.
- **Motor patterns.** Abnormal motor patterns include the loss of balance, abnormal posture, and inappropriate, involuntary movements of the body. For example, chorea is an exaggerated and sudden jerking of a body part.

Diagnostic Procedures

Common diagnostic procedures to determine neurologic disorders include the following tests:

- **Lumbar puncture (spinal tap).** When a physician needs to examine cerebrospinal fluid (CSF), a lumbar puncture is performed. A needle is used to remove CSF from the subarachnoid space, usually below the third lumbar vertebra of the spinal column. Analysis of this fluid provides a great deal of information about the patient's health. For example, cancer cells in CSF often indicate a brain tumor or spinal cord tumor. White blood cells in this fluid indicate infections such as meningitis. Red blood cells indicate abnormal bleeding.

FIGURE 29-14 Comparison of the parasympathetic and sympathetic branches.

- **Magnetic resonance imaging (MRI).** This procedure allows the brain and spinal cord to be visualized from many angles. It uses powerful magnets to generate images and is useful in detecting tumors, bleeding, and other abnormalities.
- **Positron emission tomography (PET) scan.** This procedure uses radioactive chemicals that collect in specific areas of the brain. These chemicals allow images of those areas to be generated. This test is useful in detecting brain tumors, checking blood flow to different areas of the brain, and diagnosing diseases such as Parkinson’s and Alzheimer’s.
- **Cerebral angiography.** This procedure uses contrast material that can be visualized in the blood vessels of the brain. It is useful in detecting aneurysms (abnormal, blood-filled bulges in blood vessels).
- **Computerized tomography (CT) scan.** This procedure produces images that provide more information than a standard X-ray. It is useful in detecting tumors, abnormal structures, and bleeding.
- **Electroencephalogram (EEG).** This test detects electrical activity in the brain. It is useful in diagnosing various states of consciousness.

- **X-ray.** This procedure is useful in detecting skull or vertebral fractures.

Cranial Nerve Tests

Disorders of the cranial nerves can be determined using the following tests:

- The olfactory nerves (I) are tested by asking a patient to smell various substances.
- Cranial nerves III, IV, and VI are tested by asking a patient to track the movement of the physician’s finger. If a patient cannot move her eyeballs properly, there may be damage to one of these nerves. Recall that these nerves control the muscles that move the eyeballs.
- Cranial nerve V controls the muscles needed for chewing. To assess this nerve, a patient is asked to clench his teeth. The physician then feels the jaw muscles. If the muscles feel limp or weak, this nerve may be damaged.
- If a person can no longer make facial expressions, then cranial nerve VII may be damaged. This nerve controls the muscles needed to make facial expressions.
- If a patient cannot extend his tongue and move it from side to side, cranial nerve XII may be damaged. This nerve controls tongue movement.

Reflex Testing

Testing a patient's reflexes allows a physician to evaluate the components of a reflex as well as the overall health of the individual's nervous system. The absence of a reflex is called *areflexia*. *Hyporeflexia* is a decreased reflex, and *hyperreflexia* is a stronger than normal reflex. The following are common reflex tests:

- Biceps reflex. The absence of this reflex may indicate spinal cord damage in the cervical region.
- Knee reflex. The absence of this reflex may indicate damage to lumbar or femoral nerves.
- Abdominal reflexes. These reflexes are tested to evaluate damage to thoracic spinal nerves.

PATHOPHYSIOLOGY

LO 29.7

Common Diseases and Disorders of the Nervous System

ALZHEIMER'S DISEASE is a progressive, degenerative disease that occurs in the brain.

Causes. Fiber tangles within neurons, degenerating nerve fibers, and a decreased production of neurotransmitters cause the symptoms of this disorder. Alzheimer's is associated with advanced age, family history, certain genes, and possibly some environmental factors. Many causes have not yet been determined.

Signs and Symptoms. Common symptoms include memory loss, confusion, personality changes, language deterioration, impaired judgment, and restlessness.

Treatment. There is no cure, but with medications such as Aricept®, Cognex®, Razadyne®, and Namenda®, as well as proper nutrition, physical exercise, social activity, and calm environments, the disease progress may be slowed and managed.

AMYOTROPHIC LATERAL SCLEROSIS (ALS), commonly known as Lou Gehrig's disease, is a fatal disorder characterized by the degeneration of neurons in the spinal cord and brain.

Causes. Most causes are unknown, but researchers suspect that they involve hereditary and environmental factors.

Signs and Symptoms. Early symptoms include cramping of hand and feet muscles, persistent tripping and falling, chronic fatigue, and slurred speech. Signs and symptoms that appear in later stages include breathing difficulty and muscle paralysis.

Treatment. There is no cure for this disorder; however, physical, speech, and respiratory therapies help to manage the symptoms. Some medications relieve muscle cramping, but currently only the drug riluzole is approved by the US Food and Drug Administration (FDA) specifically for ALS.

BELL'S PALSY is a disorder in which facial muscles are very weak or totally paralyzed.

Causes. This condition can result from damage to cranial nerve VII (the facial nerve), but many times the cause is unknown. It is more common in people with diabetes, the flu, or a cold.

Signs and Symptoms. The most common signs and symptoms are a loss of feeling in the face, the inability to produce facial expressions, headache, and excessive tearing or drooling.

Treatment. Treatments include the use of eyedrops, anti-inflammatory medications, and pain relievers. Symptoms usually diminish or go away within 5 to 10 days.

BRAIN TUMORS AND CANCERS are abnormal growths in the brain. A brain tumor with cancer cells is termed malignant. Malignant tumors that start in any tissue of the brain are called primary brain cancers. Those that start in other body parts and spread to the brain are classified as secondary brain cancers. The most common primary brain tumors are *gliomas* that arise from neuroglial cells.

Causes. Like most cancers, the causes are gene mutations. Factors associated with gene mutations include exposure to toxins, an impaired immune system, and hereditary factors.

Signs and Symptoms. The signs and symptoms depend on the size and location of the tumor. Common symptoms include headache, seizures, nausea, weakness in the arms or legs, fatigue, changes in speech patterns, and a loss of memory.

Treatment. Treatment options include surgery, radiation therapy, chemotherapy, and gene therapy. The success of the treatment depends on the type of tumor, the location and extent of the tumor, the tumor's response to treatment, and the patient's overall health.

EPILEPSY AND SEIZURES occur when parts of the brain receive a burst of electrical signals that disrupt normal brain functioning. Seizures may be either petit mal (partial) or grand mal (generalized). Petit mal seizures may appear as loss of awareness of the present, whereas grand mal seizures result in the classic tonic-clonic seizure, in which the person becomes unconscious and muscles twitch sporadically. Epilepsy is the condition of having repeated seizures over a long period of time.

Causes. Causes vary but may include birth trauma, high fevers, alcohol and drug withdrawal, head trauma, infections, brain tumors, and certain medications. Many causes are unknown.

Signs and Symptoms. The signs and symptoms may include visual disturbances, nausea, generalized abnormal feelings, a loss of consciousness, and uncontrolled muscle contractions and tremors.

Treatment. The primary treatment is medication to prevent seizures. Surgery is sometimes an option in patients with partial seizures.

GUILLAIN-BARRÉ SYNDROME is a disorder in which the body's immune system attacks part of the peripheral nervous system. It usually has a sudden and unexpected onset.

Causes. The destruction of myelin by the body's immune system produces the signs and symptoms. Viral infections, immunizations, and pregnancy sometimes trigger the disease.

Signs and Symptoms. Symptoms may include weakness or tingling sensations in the legs or arms that can progress to paralysis. Difficulty breathing and an abnormal heart rate are more dangerous signs and symptoms. The disease normally runs its course, and with proper medical treatment, it is not fatal.

Treatment. Various supportive therapies, such as the use of respirators and heart machines, are necessary until the disease subsides. Physical therapy is used to keep muscles strong.

MENINGITIS is an inflammation of the meninges.

Causes. Causes include bacterial, viral, and fungal infections. Some types of meningitis can be prevented with vaccines.

Signs and Symptoms. Fever, headache, vomiting, stiffness in the neck, sensitivity to light, drowsiness, and joint pain usually accompany this disorder.

Treatment. The treatment varies depending on the type of meningitis. Intravenous antibiotics are used for bacterial meningitis, supportive therapy for viral meningitis, and antifungal drugs for fungal meningitis. Bacterial meningitis can be fatal.

MULTIPLE SCLEROSIS (MS) is a chronic disease of the central nervous system in which myelin is destroyed.

Causes. The causes are mostly unknown, but some known causes are viruses, genetic factors, and immune system abnormalities.

Signs and Symptoms. Depending on the type of MS, symptoms can range from mild to severe. In severe cases, a person loses the ability to walk or speak.

Treatment. There is no cure for MS, but supportive treatments may lessen the symptoms. Some medications, including interferon, Copaxone®, prednisone, and Solu-Medrol®, are available to treat and slow the progression of symptoms.

NEURALGIAS are a group of disorders commonly referred to as nerve pain. They most frequently occur in the nerves of the face.

Causes. There are many causes of neuralgia, including trauma, chemical irritation of the nerves, bacterial infections, and diabetes. Many times the causes are unknown.

Signs and Symptoms. Sudden and severe skin pain is the most common symptom. The pain occurs repeatedly in the same body area. Numbness of skin areas is also common.

Treatment. Many times the disorder goes away spontaneously, and treatment, other than pain medication, is not needed. Other treatments include injections of anesthetics or surgery to remove the affected nerves.

PARKINSON'S DISEASE is a motor system disorder. It is slowly progressive and degenerative.

Causes. Most causes are undetermined, although it is known that patients with this disease lack certain chemicals (neurotransmitters) in the brain. Brain tumors, certain drugs, carbon monoxide, or repeated head trauma may produce Parkinson's disease.

Signs and Symptoms. The most common signs and symptoms include tremor and stiffness of the arms and legs as well as a lack of coordination and balance. A mask face, where the patient shows little or no facial emotion, is also common, as is stooped posture with a shuffling gait.

Treatment. There is no cure, but medications such as dopamine, selegiline, and Symmetrel® alleviate some symptoms and slow the progression of this disease. Surgery is useful in some cases of Parkinson's.

SCIATICA occurs when the sciatic nerve is damaged.

Causes. The sciatic nerve is commonly damaged by excessive pressure on the nerve from prolonged sitting or lying down. It is also easily damaged from trauma to the pelvis, buttocks, or thighs.

Signs and Symptoms. The most usual symptoms include numbness, pain, or tingling sensations on the back of a leg or foot. Weakness of leg and foot muscles can also develop.

Treatment. This disorder is usually treated with pain and anti-inflammatory medication or steroids. Physical therapy is also needed following trauma to the nerve.

STROKE occurs when brain cells die because of an inadequate blood flow. The medical term is *cerebrovascular accident (CVA)*. It is not uncommon for a stroke to be preceded by *transient ischemic attacks (TIAs)*, or "mini strokes," which are caused by brief interruptions of blood supply to the brain.

Causes. Most strokes are caused by the blockage of an artery in the neck or brain. They may also be caused by aneurysms that burst.

Signs and Symptoms. Signs and symptoms may include paralysis, speech problems, memory and reasoning deficits, coma, and possibly death. Symptoms vary depending on the location of the stroke within the brain.

Treatment. Because neurons in the brain cannot be replaced, the effects of a stroke can be permanent. However, physical, occupational, and speech therapy are often very useful in lessening the effects of a stroke.

HEADACHES

Headaches affect almost everyone at some point in life. A wide variety of factors produce headaches. Most headaches do not require medical attention, but a physician should evaluate repetitive and severe headaches. Headache types commonly include tension headaches, migraines, and cluster headaches.

EPISODIC TENSION headaches are the most common type of tension headache.

Causes. This type of headache is often the result of temporary stress or anger.

Signs and Symptoms. Symptoms include pain or soreness in the temples and the contraction of head and neck muscles.

Treatment. Most of these headaches can be managed by taking an over-the-counter (OTC) medicine, and relief usually occurs in 1 or 2 hours.

CHRONIC TENSION HEADACHES occur almost daily and persist for weeks or months.

Causes. This type of headache may be the result of stress or fatigue, but it may also be associated with physical problems, psychological issues, or depression.

Signs and Symptoms. As with episodic tension headaches, the symptoms include pain or soreness in the temples and the contraction of head and neck muscles.

Treatment. People who suffer from chronic headaches should seek medical treatment. Treatment may begin by identifying situations or actions that trigger the tension that causes the headaches and then developing healthy habits to remove the source of the tension. When this is not possible, or if the source of the headaches or tension is unknown, medications may be prescribed to prevent or relieve tension headaches.

MIGRAINES are the most severe type of headache. They are responsible for more “sick days” than any other headache type. Almost 30 million people in the United States suffer from migraines.

Causes. Hormones may influence migraines, which may explain why women experience migraines at least three times more often than men do. Migraines are considered vascular headaches because they are associated with the distension of the arteries of the brain.

Signs and Symptoms. Migraines often begin as dull pains that develop into throbbing pains accompanied by nausea and sensitivity to light and noise. There are many types of migraines,

but the two most common classifications are migraine with aura and migraine without aura. Auras may include the appearance of jagged lines or flashing lights, tunnel vision, hallucinations, or the detection of strange odors. The auras may last up to an hour and usually go away as the headache begins. Most migraine headaches last about 4 hours, but some can last up to a week.

Treatment. When treating migraines, a physician may prescribe a drug to relieve the pain but also try to identify the factors that trigger it. Many medicines, both OTC and prescription, are available to prevent or treat migraines.

CLUSTER HEADACHES are so named because the attacks come in groups. More men than women experience these types of headaches.

Causes. Some research indicates that alcohol consumption can bring on attacks of cluster headaches.

Signs and Symptoms. Common symptoms include a runny nose, watery eyes, and swelling below the eyes. Cluster headaches normally last about 45 minutes to an hour, although they can last longer. It is common for a patient with this disorder to experience one to four headaches a day during a cluster time span. Cluster time spans can last weeks or months.

Treatment. One of the most effective treatments for cluster headaches is 100% oxygen administration. Several types of medications are available as well, including Imitrex® (which is also used for migraine headaches), as well as local anesthetics. Preventive treatments include verapamil and medications to reduce inflammation.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
29.1 Describe the general functions of the nervous system.	The central nervous system (CNS) is composed of the brain and spinal cord. The peripheral nervous system (PNS) consists of the peripheral nerves located throughout the body. Three types of neurons carry out the functions of the nervous system: the afferent (sensory) nerves detect sensation or other stimuli from the body or environment and take it to the CNS for interpretation, the efferent (motor) nerves produce movement or other functions at the direction of the CNS, and the interneurons act as “interpreters” between the afferent and efferent nerves.
29.2 Summarize the structure of a neuron.	All neurons are composed of a cell body, the shorter and more numerous dendrites that receive information for the cell body, and the longer axons that take impulses from the cell body to the dendrite of the next neuron.

LEARNING OUTCOMES	KEY POINTS
29.3 Explain the function of nerve impulses and the role of synapses in their transmission.	Nerve impulses send information either from the central nervous system to the peripheral nervous system or vice versa. A synapse is the space between the axon of one neuron and the dendrite of the next. At the end of each axon is the synaptic knob, which contains vesicles that produce neurotransmitters. These are released by the synaptic knob to transmit the nerve impulse to the next neuron.
29.4 Describe the structures and functions of the central nervous system.	The brain consists of the cerebrum, diencephalon, brainstem, and cerebellum. The blood-brain barrier is a layer of tightly woven capillaries that protects the delicate brain tissues. The meninges are a triple-layered membrane protecting the brain and spinal cord. The spinal cord is continuous with the brain and consists of 31 spinal segments. The basic function of the spinal cord is to carry sensory information from the body to the brain and motor information from the brain to the muscles and glands of the body. Cerebrospinal fluid (CSF) is located within the subarachnoid space of the brain and within the central canal of the spinal cord. It cushions the brain and spinal cord.
29.5 Compare the structures and functions of the somatic and autonomic nervous systems in the peripheral nervous system.	The somatic nervous system connects the central nervous system to the skin and skeletal muscle (voluntary functions). The autonomic nervous system connects the CNS to the internal organs (involuntary functions). The autonomic nervous system is divided into the sympathetic branch, which prepares the body for “fight or flight” (stressful) situations, and the parasympathetic branch, which is the body’s everyday “resting” system for normal situations.
29.6 Recognize common tests that are performed to determine neurologic disorders.	Tests commonly used to determine neurologic disorders include tests of the reflexes and cranial nerves, as well as diagnostic procedures such as lumbar puncture (spinal tap), MRI, PET, cerebral angiography, CT scan, EEG, and X-ray.
29.7 Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the nervous system.	There are many common diseases and disorders of the nervous system with varied signs, symptoms, and treatments. Some of these include Alzheimer’s disease, amyotrophic lateral sclerosis (ALS), Bell’s palsy, brain tumors, cancer, epilepsy, seizures, Guillain-Barré syndrome, episodic and chronic tension headaches, migraines, cluster headaches, meningitis, multiple sclerosis (MS), neuralgias, Parkinson’s disease, sciatica, and stroke (cerebrovascular accident, or CVA).

CASE STUDY CRITICAL THINKING

© John Lund/Sam Diephuis/
Blend Images LLC RF

Recall Nancy Evans from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. Forgetfulness is a common sign of what types of neurologic disorders?
2. What are some of the possible causes of these disorders?

3. What information might the physician hope to gain from the ordered MRI, PET scan, and lumbar puncture?
4. What are the treatment options for these disorders?

EXAM PREPARATION QUESTIONS

1. (LO 29.6) Which of the following is *not* a common symptom of patients with neurologic disorders?
 - a. Headache
 - b. Paresthesia
 - c. Fever
 - d. Muscle weakness
 - e. Numbness
2. (LO 29.6) Which of the following diagnostic procedures is done to detect blood flow within the brain for diagnosing brain tumors, Parkinson's disease, and Alzheimer's disease?
 - a. MRI
 - b. PET scan
 - c. CT scan
 - d. Cerebral angiography
 - e. X-ray
3. (LO 29.4) The _____ are interconnecting cavities of the brain that produce and circulate CSF.
 - a. Ventricles
 - b. Lobes
 - c. Convolutions
 - d. Gyri
 - e. Sulci
4. (LO 29.1) What kind of neurons connect the neurons that carry messages to the central nervous system with those that carry messages from the central nervous system to the muscles and glands?
 - a. Efferent neurons
 - b. Sensory neurons
 - c. Afferent neurons
 - d. Motor neurons
 - e. Interneurons
5. (LO 29.2) Which type of neuroglial cells anchor blood vessels to the nerve cells?
 - a. Microglia
 - b. Oligodendrocytes
 - c. Astrocytes
 - d. Schwann cells
 - e. Satellite cells
6. (LO 29.4) What is the name of the tough, outer layer of the meninges?
 - a. Dura mater
 - b. Epidural space
 - c. Arachnoid mater
 - d. Subdural space
 - e. Pia mater
7. (LO 29.3) Which two ions are responsible for cell membrane depolarization and repolarization?
 - a. Na^+ and Ca^{++}
 - b. Na^+ and Cl^-
 - c. Ca^{++} and Cl^-
 - d. K^+ and Na^+
 - e. K^+ and SO_4^-
8. (LO 29.5) Collections of neuron cell bodies outside the central nervous system that communicate with organs and blood vessels are called
 - a. Ganglia
 - b. Plexuses
 - c. Dermatomes
 - d. Ventral roots
 - e. Dorsal roots

9. (LO 29.5) Which of the following cranial nerves are found in the muscles of the tongue?
 - a. Olfactory nerves (I)
 - b. Oculomotor nerves (III)
 - c. Trigeminal nerves (V)
 - d. Facial nerves (VII)
 - e. Hypoglossal nerves (XII)
10. (LO 29.7) In which nervous system disorder are the facial muscles paralyzed?
 - a. Amyotrophic lateral sclerosis
 - b. Epilepsy
 - c. Bell's palsy
 - d. Guillain-Barré syndrome
 - e. Meningitis

M E D I C A L T E R M I N O L O G Y P R A C T I C E

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **crani/ otomy** = crani means “skull” + otomy means “incision”
CRANIOTOMY means “incision into the skull.”

- | | | |
|----------------|-------------------------|----------------------|
| 1. angiography | 5. electroencephalogram | 9. neuralgia |
| 2. areflexia | 6. hyperreflexia | 10. neurotransmitter |

when he urinates. He has also been very tired lately. Based on the vital signs you measured and Peter's current complaints, the physician ordered a fasting blood glucose and a urinalysis.

Keep Peter in mind as you study the chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 30, you will be able to:

- 30.1** Describe the structure, location, and functions of the kidneys.
- 30.2** Explain how nephrons filter blood and form urine.
- 30.3** Compare the locations, structures, and functions of the ureters, bladder, and urethra.
- 30.4** Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the urinary system.

KEY TERMS

Bowman's capsule	renal column
detrusor muscle	renal corpuscle
distal convoluted tubule	renal cortex
glomerulus	renal medulla
hilum	renal pelvis
lithotripsy	renal pyramids
loop of Henle	renal sinus
metabolic wastes	renal tubule
micturition	trigone
nephrons	ureters
proximal convoluted tubule	urethra

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.6** Compare structure and function of the human body across the life span
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms, and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each system

3. Medical Terminology

- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

► Introduction

The organs of the urinary system are the kidneys, ureters, urinary bladder, and urethra (see Figure 30-1). This system removes waste products from the bloodstream. These waste products are excreted from the body in the form of urine. **Nephrons** are microscopic structures within the kidneys that filter blood, remove waste products, and form urine.

FIGURE 30-1 Organs of the urinary system.

► The Kidneys

LO 30.1

The kidneys remove metabolic waste products from the blood. **Metabolic wastes** are the waste products produced during normal operations such as converting food into a form that is usable by the body cells for energy. In the kidneys, metabolic wastes are combined with water and ions to form urine, which is excreted from the body. The kidneys also secrete the hormone *erythropoietin*, which stimulates the red bone marrow to produce red blood cells, and the hormone *renin*, which helps to regulate blood pressure. All three of these functions are important in maintaining the body's internal environment at homeostasis, which is a balanced, stable state within the body.

The kidneys are reddish-brown, bean-shaped organs. Tough, fibrous capsules cover them. The kidneys are *retro-peritoneal* in position, which means they lie behind the peritoneal cavity. They lie on either side of the vertebral column at about the level of the lumbar vertebrae; the left kidney is slightly higher than the right, which is displaced by the liver.

The surface area of the concave depression of the kidney is called the **renal sinus**. The renal artery, renal vein, and ureter enter the kidney here in the area known as the **hilum**. The ureter is the tube that drains urine from the kidney, carrying it to the bladder. Inside the kidney, the same area is called the **renal pelvis**, formed by the expansion of the ureter inside the kidney. The renal pelvis itself further divides into small tubes known as *calyces* (*calyx* is the singular).

The outermost layer of the kidney is the **renal cortex**, and the middle portion is the **renal medulla** (see Figure 30-2). The renal medulla is divided into triangular-shaped areas called

FIGURE 30-2 (a) Longitudinal section of a kidney, (b) the location of nephrons, and (c) a single nephron.

renal pyramids. The renal cortex covers the pyramids and dips down between them. The portions of the cortex located between pyramids are called **renal columns**.

Blood enters the kidney through the renal artery and goes through the filtration process explained in the next section. It then exits the kidney via the renal vein.

Nephrons

Nephrons remove waste products from the blood. Each kidney contains about 1 million nephrons, which are located in the renal medulla. Nephrons are made up of a **renal corpuscle** and a **renal tubule** (see Figure 30-2). A renal corpuscle is composed of a mass of capillaries called a **glomerulus**; the capsule that surrounds the glomerulus is called the **Bowman's capsule**, or *glomerular capsule*. Blood filtration occurs in the renal corpuscle.

Renal tubules extend from the Bowman's capsule of a nephron. The three parts of a renal tubule are the **proximal convoluted tubule**, the **loop of Henle** (*nephron loop*), and the **distal convoluted tubule** (see Figure 30-3). The proximal convoluted tubule is directly attached to the Bowman's capsule and eventually straightens out to become the loop of Henle. The loop of Henle curves back toward the renal corpuscle and starts to twist again, becoming the distal convoluted tubule. Distal convoluted tubules from several nephrons merge to form collecting ducts. These ducts collect urine and deliver it to the renal pelvis, which in turn empties urine into the ureters.

Afferent arterioles take blood to the tightly packed, increasingly narrow capillaries of the glomeruli. This narrowing causes the filtration of the blood. The blood is forced through the capillary walls, similar to what occurs when water drips through a coffee filter in a drip coffee-maker. Efferent arterioles deliver blood to *peritubular capillaries*, which are wrapped around the renal

tubules of the nephron. Blood leaves the peritubular capillaries through the veins of the kidneys. By the time the blood leaves the peritubular capillaries, it has been cleansed of waste products.

Blood flows through a nephron in the following pathway:

afferent arteriole → glomerulus → efferent arteriole → peritubular capillaries → veins of the kidney

Urine Formation

LO 30.2

The three processes of urine formation are glomerular filtration, tubular reabsorption, and tubular secretion.

Glomerular Filtration

Glomerular filtration takes place in the renal corpuscles of nephrons. In this process, the fluid part of blood is forced from the glomerulus (the capillaries) into Bowman's capsule (see Figure 30-4). The fluid in Bowman's capsule is called the *glomerular filtrate*.

Glomerular filtration depends on filtration pressure, which is the pressure that forces substances (filtrate) out of the glomerulus into Bowman's capsule. Filtration pressure is largely determined by blood pressure. If a person's blood pressure is too low, glomerular filtrate will not form. If the blood pressure increases, filtration pressure also increases, causing the rate of filtration and the amount of glomerular filtrate to increase as well.

The sympathetic branch of the autonomic nervous system largely controls the rate of filtration. If blood pressure or blood volume drops, the sympathetic nervous system causes the afferent arterioles in the kidneys to constrict. When this constriction occurs, glomerular filtration pressure decreases and less glomerular filtrate is formed. When less glomerular

FIGURE 30-3 Structure of a nephron and its associated blood vessels.

FIGURE 30-4 Glomerular filtration. (a) Substances move out of glomerular capillaries and into Bowman's capsule. (b) Glomerular capillaries have large holes called *fenestrae* that allow substances to move out of them and into Bowman's capsule.

filtrate is formed, less urine is ultimately formed. This allows the body to retain fluids that are needed to raise blood pressure and blood volume.

Tubular Reabsorption

Tubular reabsorption is the second process in urine formation. In this process, the glomerular filtrate flows into the proximal convoluted tubule (see Figure 30-5a). The body needs to keep many of the substances (nutrients, water, and ions) that are found in glomerular filtrate. In tubular reabsorption, all the substances to be kept pass through the wall of the renal tubule into the blood of the peritubular capillaries.

Water reabsorption varies depending on the presence of two hormones: antidiuretic hormone (ADH) and aldosterone. Both of these hormones increase water reabsorption, which decreases urine production. This fluid retention and the resultant increase in blood pressure is one of the reasons diuretics, which rid the body of excess fluid, are successful in treating some forms of hypertension.

Tubular Secretion

Tubular secretion is the third process of urine formation. In tubular secretion, substances move from the blood in the peritubular capillaries into the renal tubules (see Figure 30-5b). Substances that are secreted include drugs, hydrogen ions, and waste products, all of which will be excreted in the urine.

Urine Composition

The final solution that reaches the collecting ducts of the kidneys is urine. Urine is mostly made of water but also normally

contains urea, uric acid, trace amounts of amino acids, and various ions. *Urea* and *uric acid* are waste products formed by the breakdown of proteins and nucleic acids. The secretion of these waste materials helps maintain the body's acid-base balance.

► The Ureters, Urinary Bladder, and Urethra

LO 30.3

The remaining organs in the urinary system transport and store urine after it is formed in the kidneys.

The Ureters

The **ureters** are long, muscular tubes that carry urine from the kidneys to the urinary bladder. They propel urine toward the bladder through rhythmic muscular contractions of the ureters called *peristalsis*.

The Urinary Bladder

The urinary bladder is a distensible (expandable) organ located in the pelvic cavity. Its function is to store urine (up to 600 mL on average) until it is eliminated from the body. The internal floor of the bladder contains three openings—one for the urethra and two for the ureters. These three openings form a triangle called the **trigone** of the bladder. The wall of the bladder contains smooth muscle, called the **detrusor muscle**. This muscle contracts to push urine from the bladder into the urethra (see Figure 30-6).

Micturition is the process of urination. The stretching of the bladder triggers this process—usually when the bladder

FIGURE 30-5 (a) Tubular reabsorption. Substances move from the glomerular filtrate into the blood of peritubular capillaries. (b) Tubular secretion. Substances move out of the blood of the peritubular capillaries into the renal tubule.

FIGURE 30-6 Male urinary bladder: (a) anterior view and (b) posterior view.

contains approximately 150 mL of urine. The major events of micturition are the following:

1. The urinary bladder distends as it fills with urine.
2. The distension stimulates stretch receptors in the bladder wall, which sends a nerve impulse to in the spinal cord.
3. Parasympathetic nerves stimulate the detrusor muscle, which begins rhythmic contractions that trigger the sense of the need to urinate.
4. The brainstem and cerebral cortex send impulses to voluntarily contract the external urethral sphincter and to inhibit the micturition impulse.
5. Upon the decision to urinate, the external urethral sphincter is relaxed and impulses from the pons and hypothalamus start the micturition reflex.
6. Contraction of the detrusor muscle occurs and urine is expelled through the urethra.

The Urethra

The **urethra** is a tube that moves urine from the bladder to the outside world. In females, the urethra is much shorter than in males. This anatomical difference, combined with the fact that the anus, vagina, and urethra are in close proximity in females, makes females much more susceptible to urinary tract infections (UTIs).

EDUCATING THE PATIENT

Preventing Urinary Cystitis in Women

Urinary cystitis and other UTIs can cause pain (dysuria), urgency, and frequency. Because the female anatomy makes women more prone to these problems, educate your female patients to take these steps:

1. **Urinate when the urge occurs.** When you “hold it,” urine stays in the bladder and the upper urethra, allowing bacteria to grow and cause infection.
2. **Drink lots of clear fluids.** This is known as “pushing fluids.” The more clear liquids you drink, the more urine is created and the system is flushed on a regular basis. Cranberry juice is highly recommended as a preventive fluid, as well as part of the treatment if infection does occur.
3. **Wipe front to back.** Teach your female patients they should wipe “front to back” after a bowel movement. Doing so prevents contamination of both the vagina and urethra by gastrointestinal (GI) bacteria such as *E. coli*. Maintaining excellent hygiene in the perineal area is an important component of UTI and cystitis prevention.
4. **Urinate after sexual intercourse.** Explain to your sexually active patients that urinating immediately after sexual intercourse will also help prevent episodes of cystitis. The urine will flush out contamination that could enter the bladder, causing an infection.

If cystitis or UTI does strike despite preventive methods, reassure your patient that antibiotics and lots of fluids should take care of the problem. If the patient suffers from more than three infections during a year, a urologic workup may be advisable to look for underlying anatomical anomalies.

Common Diseases and Disorders of the Urinary System

ACUTE KIDNEY (RENAL) FAILURE is a sudden loss of kidney function.

Causes. There are many causes and risk factors of kidney failure, including burns, dehydration, low blood pressure, hemorrhaging, allergic reactions, obstruction of the renal artery, various poisons, alcohol abuse, trauma to the kidneys and skeletal muscles, blood disorders, blood transfusion reactions, kidney stones, urinary tract infections, enlarged prostate, childbirth, immune system disorders, and food poisoning involving the bacterium *E. coli*.

Signs and Symptoms. The signs and symptoms include decreased or no urine production, excessive urination, swelling of the extremities, bloating, mental confusion, coma, seizures, hand tremors, nosebleeds, easy bruising, pain in the back or abdomen, hypertension, abnormal heart or lung sounds, abnormal urinalysis, and an increase in potassium levels.

Treatment. The first treatment measure is modifying the diet to decrease the amount of protein consumed. Controlling fluid intake and potassium levels is also recommended. Antibiotics and dialysis may also be needed. If the underlying cause can be treated, acute renal failure may be reversed and kidney function returned to normal.

CHRONIC KIDNEY (RENAL) FAILURE is a condition in which the kidneys slowly lose their ability to function. The patient may be asymptomatic until the kidneys have lost about 90% of their function.

Causes. This disorder results from diabetes, hypertension, glomerulonephritis, polycystic kidney disease, kidney stones, obstruction of the ureters, and acute kidney failure.

Signs and Symptoms. The list of signs and symptoms is extensive and includes headache, mental confusion, coma, seizures, fatigue, frequent hiccups, itching, easy bruising, abnormal bleeding, anemia, excessive thirst, fluid retention, nausea, hypertension, abnormal heart or lung sounds, weight loss, white spots on the skin or increased pigmentation, high potassium levels, an increased or decreased urine output, urinary tract infections, and abnormal urinalysis results.

Treatment. This disorder can be treated with antibiotics; blood transfusions; medications to control anemia; restriction of fluids, electrolytes, and protein; control of high blood pressure; and dialysis. The most serious cases may require surgery to repair a ureteral obstruction or a kidney (renal) transplant.

CYSTITIS is a urinary bladder infection. Women are much more likely to develop this disorder than men because of the short length of their urethras. The urethral opening in women is also close to the anal opening, allowing bacteria from this area to be more easily

introduced into the urinary tract. For more information on preventing urinary cystitis in women, see the *Educating the Patient* feature.

Causes. This infection is caused by various types of bacteria (especially those found in the rectum), as well as by the placement of a catheter in the bladder. Good hygiene, urinating promptly when the urge occurs, and, for females, wiping from front to back can help to prevent this infection.

Signs and Symptoms. Common symptoms include fatigue, chills, fever, and a painful, frequent need to urinate, often with only small amounts of urine produced. Urine is often cloudy and blood may be present in the urine.

Treatment. This infection is treated with antibiotics and, when needed, pain medication. The patient should also be urged to drink lots of clear liquids.

GLOMERULONEPHRITIS is an inflammation of the glomeruli of the kidney. Chronic glomerulonephritis is one of the causes of chronic renal failure.

Causes. This disorder is caused by renal diseases, immune disorders, and bacterial infections.

Signs and Symptoms. The signs and symptoms are hiccups, drowsiness, coma, seizures, nausea, anemia, high blood pressure, increased skin pigmentation, abnormal heart sounds, abnormal urinalysis results, blood in the urine, and a decreased or increased urine output.

Treatment. Treatment begins with a low-sodium, low-protein diet. Medications to control high blood pressure, corticosteroids to reduce inflammation, and dialysis are other treatment options.

INCONTINENCE is a temporary or long-lasting condition in which a person (other than a child) cannot control urination. Women are more likely to develop incontinence than men are.

Causes. This condition can be caused by various medications, excessive coughing (for example, in smokers), UTIs, nervous system disorders, and bladder cancer. In men, prostate problems can lead to the development of this disorder. Weakness of the urinary sphincters from surgery, trauma, or pregnancy can also cause incontinence. It may be prevented by avoiding urinary bladder irritants such as coffee, cigarettes, diuretics, and various medications.

Signs and Symptoms. The primary symptom is the involuntary leakage of urine.

Treatment. Treatment includes various medications, incontinence pads, removal of the prostate, Kegel exercises to increase the control of urinary sphincters, and surgery to repair damaged bladders or urethral sphincters.

POLYCYSTIC KIDNEY DISEASE is a disorder in which the kidneys enlarge because they are filled with cysts. The disease develops relatively slowly, with symptoms worsening over time.

Causes. The causes are hereditary (via an inherited dominant gene from a parent).

Signs and Symptoms. Fatigue, hypertension, anemia, pain in the back or abdomen, joint pain, heart murmurs, the formation of kidney stones, kidney failure, blood in the urine, and liver disease are the symptoms of this disorder.

Treatment. Treatment includes medications to control anemia and high blood pressure, blood transfusions, draining of the cysts, dialysis, and surgery to remove one or both kidneys.

PYELONEPHRITIS is a complicated UTI. It begins as a bladder infection and spreads to one or both kidneys. This condition can develop suddenly, or it may be chronic.

Causes. This disorder is caused by bacteria, a bladder infection, kidney stones, or an obstruction of the urinary system ducts.

Signs and Symptoms. Signs and symptoms include fatigue, mental confusion, fever, nausea, pain in the back or abdomen, enlarged kidneys, painful urination, and cloudy or bloody urine.

Treatment. Treatment includes intravenous fluids, pain medication, and antibiotics.

RENAL CALCULI are commonly called *kidney stones*. They can become lodged in the ducts within the kidneys or ureters, causing more severe disorders such as pyelonephritis and chronic kidney failure.

Causes. This condition is caused by gouty arthritis, defects of the ureters, overly concentrated urine, and UTIs.

Signs and Symptoms. The signs and symptoms include fever, nausea, severe back or abdominal pain, a frequent urge to urinate, blood in the urine, and abnormal urinalysis results.

Treatment. Treatment includes pain medication, intravenous fluids, medications to decrease stone formation, surgery to remove kidney stones, and **lithotripsy** (a procedure that uses shock waves to break up stones).

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
30.1 Describe the structure, location, and functions of the kidneys.	The retroperitoneal kidneys are composed of the outer renal cortex and inner renal medulla. Their function is to remove metabolic wastes from the body.
30.2 Explain how nephrons filter blood and form urine.	A nephron is a single kidney cell. It is composed of a renal corpuscle, which consists of the glomerulus and the Bowman’s capsule, and the renal tubule, which has three parts: the proximal convoluted tubule, the loop of Henle, and the distal convoluted tubule. The nephrons filter blood and form urine through three consecutive processes: glomerular filtration, tubular reabsorption, and tubular secretion.
30.3 Compare the locations, structures, and functions of the ureters, bladder, and urethra.	The ureters are long tubes extending from each renal pelvis that bring urine to the bladder for storage. The urethra is the muscular tube extending from the bladder that transports urine to be expelled from the body.
30.4 Describe the causes, signs and symptoms, and treatments of various diseases and disorders of the urinary system.	There are many common diseases and disorders of the urinary system with varied signs, symptoms, and treatments. Some of these include acute kidney (renal) failure, chronic kidney (renal) failure, cystitis, glomerulonephritis, incontinence, polycystic kidney disease, pyelonephritis, and renal calculi.

Recall Peter Smith from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. What is the likely diagnosis for Mr. Smith?
2. Why did the physician order both a urinalysis and a blood glucose test?

3. Why might Mr. Smith’s vital signs show that his temperature is slightly elevated?
4. Based on the laboratory test results, the physician prescribed an antibiotic for Mr. Smith. What can you advise Mr. Smith to do in addition to taking the antibiotic as prescribed?

EXAM PREPARATION QUESTIONS

- (LO 30.4) _____ is a complicated UTI that begins as a bladder infection and spreads to one or both kidneys.
 - Cystitis
 - Glomerulonephritis
 - Pyelonephritis
 - Polycystic kidney disease
 - Chronic renal failure
- (LO 30.2) In which of the following processes do substances move into the renal tubules?
 - Glomerular filtration
 - Tubular secretion
 - Tubular reabsorption
 - Micturition
 - Urination
- (LO 30.2) Distal convoluted tubules from several nephrons merge together to form the
 - Bowman's capsule
 - Glomerulus
 - Loop of Henle
 - Collecting ducts
 - Renal pyramids
- (LO 30.2) Water reabsorption amounts vary depending on which two hormones?
 - ADH and aldosterone
 - ADH and erythropoietin
 - Aldosterone and renin
 - Angiotensin and ADH
 - Erythropoietin and renin
- (LO 30.1) _____ is the hormone from the kidneys that stimulates the bone marrow to produce RBCs.
 - Renin
 - ADH
 - Aldosterone
 - Hematopoietin
 - Erythropoietin
- (LO 30.1) The outermost layer of the kidney is the renal
 - Cortex
 - Pelvis
 - Medulla
 - Tubule
 - Sinus
- (LO 30.1) The _____ is the structure that surrounds the glomerulus.
 - Loop of Henle
 - Proximal convoluted tubule
 - Distal convoluted tubule
 - Bowman's capsule
 - Renal pyramid
- (LO 30.2) The rate of glomerular filtration is controlled mainly by the
 - Blood pressure
 - Sympathetic branch of the autonomic nervous system
 - Somatic nervous system
 - Parasympathetic branch of the autonomic nervous system
 - Central nervous system
- (LO 30.2) Which of the following is *not* a normal component of urine?
 - Water
 - Ions
 - Glucose
 - Uric acid
 - Urea
- (LO 30.3) The _____ is a triangular area formed by the urethral and ureteral openings into the bladder.
 - Detrusor muscle
 - Renal pyramid
 - Trigone
 - Hilum
 - Calyx

MEDICAL TERMINOLOGY PRACTICE

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **nephro/logy** = nephro means “kidney” + logy means “study of”
NEPHROLOGY means “study of the kidney.”

- | | | |
|-------------------|-----------------------|---------------------|
| 1. antidiuretic | 5. glomerulonephritis | 9. peritubular |
| 2. cystitis | 6. lithotripsy | 10. pyelonephritis |
| 3. dysuria | 7. nephritis | 11. retroperitoneal |
| 4. erythropoietin | 8. peristalsis | 12. uric |

The Reproductive Systems

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Raja Lautu	8/3/19XX	Benzalkonium Chloride
PATIENT INFORMATION	Attending	MRN	Other Information
	Elizabeth H. Williams, MD	224-86-564	BP slightly elevated: 132/88. Other vital signs within normal limits.

Raja Lautu, a 46-year-old woman, has come to the office complaining of vaginal itching and a greenish vaginal discharge with a “fishy” smell. She is sexually active and

© ERproductions Ltd/Blend Images LLC RF

recently changed partners, but she says her partner has no symptoms. Dr. Williams obtains a vaginal fluid specimen and sends it to the lab for testing.

Keep Raja in mind as you study the chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 31, you will be able to:

- 31.1** Summarize the organs of the male reproductive system, including the locations, structures, and functions of each.
- 31.2** Describe the causes, signs and symptoms, and treatment of various disorders of the male reproductive system.
- 31.3** Summarize the organs of the female reproductive system, including the locations, structures, and functions of each.
- 31.4** Describe the causes, signs and symptoms, and treatment of various disorders of the female reproductive system.
- 31.5** Explain the process of pregnancy, including fertilization, the prenatal period, and fetal circulation.
- 31.6** Describe the birth process, including the postnatal period.
- 31.7** Compare several birth control methods and their effectiveness.
- 31.8** Explain the causes of and treatments for infertility.
- 31.9** Describe the causes, signs and symptoms, and treatments of the most common sexually transmitted infections.

KEY TERMS

- | | |
|--------------------|----------------------|
| amnion | menarche |
| APGAR | menopause |
| Bartholin's glands | oogenesis |
| blastocyst | ovulation |
| Cowper's glands | placenta |
| ductus arteriosus | primary germ layer |
| ductus venosus | seminiferous tubules |
| embryo | spermatogenesis |
| fetus | testes |
| foramen ovale | zygote |
| infundibulum | |

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.6** Compare structure and function of the human body across the life span
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms, and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each system

3. Medical Terminology

- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

► Introduction

The male and female reproductive systems function together to produce offspring. The female reproductive system nurtures a developing offspring. If a female breast-feeds, her breasts, considered accessory organs of both her reproductive and integumentary systems, are also used to nurture the newborn baby. The male and female reproductive systems also produce a number of important hormones before and during the reproductive years.

► The Male Reproductive System LO 31.1

The male reproductive system is responsible for developing sperm. Accessory organs also produce substances that provide an environment for the sperm that allows it to reach the female ova (eggs).

Testes

Testes are considered the primary organs of the male reproductive system because they produce the male sex cells (sperm) (see Figure 31-1). They also produce the male hormone *testosterone*. Most males have two testes that are held just below the pelvic cavity in the *scrotum*. During the fetal stage, the testes develop in the abdominopelvic cavity of the fetus. Shortly before or soon after birth, the testes descend into the scrotal sac. A fibrous capsule encloses each testis and invades the testis to divide it into lobules. Each lobule is filled with **seminiferous tubules**, which are filled with *spermatogenic cells*. These cells give rise to sperm

cells. Between the seminiferous tubules are the *interstitial cells*, which are the cells within the testes that produce testosterone.

Sperm Cell Formation Spermatogenic cells of the seminiferous tubules begin the process of making sperm cells, but the sperm cells do not mature until they travel to the *epididymis*. **Spermatogenesis** is the process of sperm cell formation. At the beginning of spermatogenesis, the cells are called *spermatogonia*. Spermatogonia contain 46 chromosomes. These cells undergo mitosis, as discussed and shown in the *Organization of the Body* chapter, and the resulting cells are called *primary spermatocytes*. Primary spermatocytes also contain 46 chromosomes. At about the time of puberty, primary spermatocytes undergo a process called *meiosis* (see Figures 31-2 and 31-3a). In meiosis, each primary spermatocyte divides to make two secondary spermatocytes. Each secondary spermatocyte divides to make two *spermatids*. Therefore, from one primary spermatocyte, four spermatids are formed. Spermatids develop flagella to become mature sperm cells. They contain only 23 chromosomes.

Structure of Sperm Cells A mature sperm (see Figure 31-3b) has the following three parts: the head, the mid-piece, and the tail.

The Head The head is oval in structure and holds a nucleus with 23 chromosomes. The head is covered with an enzyme-filled sac called an *acrosome*, which helps the sperm penetrate an ovum at the time of fertilization.

FIGURE 31-1 Sagittal view of male reproductive organs. The male reproductive system produces sperm and delivers them in a form that keeps them viable long enough to fertilize an ovum.

The Midpiece This portion of the sperm is between the head and tail. It is filled with mitochondria that generate the energy the cell needs to move.

The Tail The tail is a flagellum that propels the sperm forward in the female reproductive tract.

Internal Accessory Organs of the Male Reproductive System

The internal accessory organs of the male reproductive system are the epididymis, vas deferens, seminal vesicles, prostate gland, and bulbourethral, or Cowper's, glands.

Epididymis An epididymis sits on top of each testis. It is a highly coiled tube that receives spermatids from seminiferous tubules as the spermatids are formed. Inside the epididymis, spermatids mature to become sperm cells.

Vas Deferens A tube called a *vas deferens* is connected to each epididymis. These tubes carry sperm cells from the epididymis to the urethra in the male pelvic cavity. When a male has a vasectomy, these tubes are cut and tied to prevent sperm from reaching the ovum.

Seminal Vesicles Seminal vesicles are sac-like organs that secrete an alkaline *seminal fluid* that is rich in sugars and *prostaglandins*. Sperm cells use the sugars to make

energy, and the prostaglandins stimulate muscular contractions in the female reproductive system. These muscular contractions, known as *peristalsis*, help to propel sperm forward in the female reproductive tract. Seminal vesicles release their product into the vas deferens just before ejaculation. Seminal fluid makes up approximately 60% of semen volume.

Prostate Gland The muscular prostate gland surrounds the proximal portion of the urethra. It produces a milky, alkaline fluid and secretes this fluid into the urethra just before ejaculation. The alkaline nature of this fluid helps to protect the sperm when they enter the acidic environment of the female vagina. Prostatic fluid makes up approximately 40% of semen volume. During ejaculation, the muscular contractions of the prostate help expel semen.

Bulbourethral Glands Bulbourethral glands, or **Cowper's glands**, are inferior to the prostate gland. They produce a mucus-like fluid that is secreted into the urethra before ejaculation. This fluid lubricates the end of the penis in preparation for sexual intercourse.

Semen Semen is a mixture of sperm cells and fluids from the seminal vesicles, prostate gland, and bulbourethral glands. This alkaline mixture contains nutrients and prostaglandins. Total semen volume is between 1.5 and 5.0 mL per ejaculate,

FIGURE 31-2 The process of meiosis, including prophase, metaphase, anaphase, and telophase.

FIGURE 31-3 Spermatogenesis: (a) The process of spermatogenesis takes place in the wall of the seminiferous tubule. (b) Structural changes occur as a sperm cell forms from a spermatid.

with a sperm count between 40 and 250 million/mL. A normal sperm count is more than 80 million.

External Organs of the Male Reproductive System

The two male external reproductive organs are the scrotum and the penis (see Figure 31-1).

Scrotum The scrotum is a pouch of skin that holds the testes. It is lined with a serous membrane that secretes fluid to ensure that the testes move freely within it. The scrotum holds the testes away from the rest of the body, keeping their

temperature about 1 degree lower than the rest of the body, which is necessary for the viability of the sperm.

Penis The penis is a cylindrical organ that moves urine and semen out of the body. The shaft, or body, of the penis contains specialized *erectile tissue* that surrounds the urethra, which runs the length of the penis. The end of the penis is enlarged into a cone-shaped structure called the *glans penis*. If a male has not been circumcised, a piece of skin, called the *prepuce*, covers the glans penis. The function of the penis is to deliver sperm to the female reproductive tract. The penis also functions in urination because it contains the urethra, which drains urine from the bladder.

FIGURE 31-3 (concluded)

Erection, Orgasm, and Ejaculation

During sexual arousal, the parasympathetic nervous system causes erectile tissue of the penis to become engorged with blood, which produces erection of the penis. During orgasm, sperm cells are propelled out of the testes toward the urethra. The secretions of the prostate, seminal vesicles, and bulbourethral glands are also released into the urethra. The movement of the sperm and secretions into the urethra is called *emission*. The process of *ejaculation* occurs when semen is forced out of the urethra. After ejaculation, sympathetic nerve fibers cause the erectile tissue to release blood, and the penis gradually returns to a flaccid, or nonerect, state.

Male Reproductive Hormones

The hypothalamus, the anterior pituitary gland, and the testes secrete hormones that regulate male reproductive functions. At the onset of puberty and throughout life, the hypothalamus releases a hormone called *gonadotropin-releasing hormone (GnRH)*. GnRH stimulates the anterior pituitary gland

to release *follicle-stimulating hormone (FSH)* and *luteinizing hormone (LH)*. FSH causes spermatogenesis to begin, and LH stimulates interstitial cells to produce *testosterone*.

Testosterone is responsible for the development of male secondary sex characteristics that are typically unique to males. Examples of these characteristics include chest hair, thick facial hair, a thickening and strengthening of muscles and bones, and the thickening of vocal cords that produces a deeper voice. Testosterone also stimulates the maturation of male reproductive organs.

Testosterone levels are regulated by negative feedback in the following cycle: Blood testosterone levels increase to above normal levels, which causes the hypothalamus to release GnRH. In response, the anterior pituitary ceases the secretion of LH and FSH, in turn causing the testosterone level to fall. When the testosterone level falls below normal, GnRH is again secreted by the hypothalamus, triggering the release of LH and FSH by the anterior pituitary, and the cycle begins again.

PATHOPHYSIOLOGY

LO 31.2

Common Diseases and Disorders of the Male Reproductive System

BENIGN PROSTATIC HYPERTROPHY, OR BPH, is the non-malignant enlargement of the prostate gland. This condition is common in older men.

Causes. BPH is related to the hormonal changes that occur as part of the aging process.

Signs and Symptoms. Men with BPH often complain of frequent urination, especially at night, as well as painful urination and difficulty starting or stopping the urinary stream, including “dribbling” at the end of urination.

Treatment. Diagnosis is often confirmed by digital rectal exam (DRE), in which the licensed practitioner inserts a gloved finger into the rectum and palpates the prostate. Blood tests (PSA) and a biopsy may be done to rule out cancer. Once cancer is ruled

out, medications such as Avodart® or Flomax® may manage the problem, or *transurethral resection of the prostate (TURP)* may be performed to remove the enlarged tissue.

EPIDIDYMITIS is inflammation of an epididymis. Most cases start out as an infection of the urinary tract that spreads to an epididymis.

Causes. The causes include the use of certain medications, placement of a catheter in the urethra, and bacteria—especially those that cause gonorrhea and chlamydia.

Signs and Symptoms. Signs and symptoms include fever, pain in the testes, a lump in the testes, swelling of the scrotum, painful ejaculation, blood in the semen, pain during urination, discharge from the urethra, and enlarged lymph nodes in the pelvic area.

Treatment. Treatment includes pain medication, antibiotics for both the patient and his sexual partner, elevation of the scrotum, and ice packs applied to the scrotum.

IMPOTENCE, OR ERECTILE DYSFUNCTION (ED), is a disorder in which a male cannot achieve or maintain an erect penis to complete sexual intercourse. It is estimated that half of all men between the ages of 40 and 70 years have some degree of impotence. Most causes are physical and not psychological.

Causes. Psychological causes include anxiety, stress, and depression. Common physical causes include diabetes; high blood pressure; anemia; coronary artery disease (CAD); peripheral vascular disease (PVD); low testosterone production; various medications; smoking; excessive alcohol consumption; and drugs such as cocaine, marijuana, and heroin.

Signs and Symptoms. Signs and symptoms include an inability to achieve an erection and an inability to maintain an erection long enough to complete sexual intercourse.

Treatment. The first treatment step should be lifestyle changes to quit smoking and stop using alcohol and/or drugs. Counseling to reduce anxiety and depression may also be helpful. Other treatment options include oral medications such as Viagra® or Cialis®, penile injections of medications, and penile implants if oral medications do not work.

PROSTATE CANCER is one of the most common cancers in men older than age 40, and the risk of developing prostate cancer increases with age. Awareness about this malignancy is growing, and access to screenings such as digital rectal exam (DRE) is becoming widely available. Therefore, many cases in the United States are being diagnosed even before symptoms occur.

Causes. The causes are mostly unknown, although decreased testosterone production may contribute to the development of this disease, explaining why risk increases with age.

Signs and Symptoms. Common symptoms include anemia, weight loss, incontinence, difficulty starting or stopping

urination, painful urination, pain in the lower back or abdomen, pain during bowel movements, high levels of prostate-specific antigen (PSA) in the blood, blood in the urine, and bone pain in advanced cases when cancer cells have spread (metastasized) to the bone.

Treatment. Treatments include hormone therapy, chemotherapy, radiation therapy to shrink or destroy the tumor, and surgery to remove the prostate, known as *prostatectomy*.

PROSTATITIS is an inflammation of the prostate gland. If it develops suddenly, it is called *acute prostatitis*. The slow development of this condition is termed *chronic prostatitis*.

Causes. This condition can be caused by excessive alcohol consumption, bacterial infection, a catheterization, trauma to the urethra or urinary bladder, and scarring of the urethra or prostate because of frequent infections. Urinating frequently can help to prevent this infection.

Signs and Symptoms. Signs and symptoms include fever; pain in the scrotum, pelvic area, or abdomen; difficult, frequent, and/or painful urination; blood in the urine; painful ejaculation; blood in the semen; discharge from the urethra; a low sperm count; and white blood cells in urine or semen.

Treatment. This condition is treated with antibiotics. Surgery may also be required to repair any damage to the urethra.

TESTICULAR CANCER is a malignant growth of one or both testicles. Unlike prostate cancer, which tends to occur in older males, testicular cancer occurs in males ages 15 to 30 and is a much more aggressive malignancy.

Causes. Predisposing factors include cryptorchidism (undescended testicles during infancy). Family history may also be a factor.

Signs and Symptoms. A hard, painless lump in one testicle is a common early symptom. Patients may complain of groin or abdominal pain as the disease progresses.

Treatment. Orchiectomy, or removal of the involved testis, is usually performed, followed by radiation therapy and chemotherapy. Caught in the early stages, testicular cancer has up to a 95% success rate. It is therefore very important for males to perform testicular self-exams on a monthly basis. You will learn how to instruct patients in this important exam technique in the *Assisting in Reproductive and Urinary Specialties* chapter.

► The Female Reproductive System LO 31.3

Ovaries and Ovum Formation

The ovaries are considered the primary female sex organs because they produce the female sex cells, called *ova* (see Figures 31-4 and 31-5). They also produce *estrogen* and *progesterone*, the female hormones. Most females have two ovaries. They are oval in shape and are located in the pelvic cavity. Each ovary is divided into an inner area called the *medulla* and an outer area called the *cortex*. The medulla contains nerves, lymphatic vessels, and many blood vessels. The cortex contains small masses of cells called *ovarian follicles*. Epithelial tissue and dense connective tissue cover each ovary.

Before a female child is born, *primordial follicles* develop in her ovarian cortex. Each primordial follicle contains a large cell called a *primary oocyte* (immature ovum) and smaller cells called *follicular cells*. Unlike males, who make sperm cells throughout their entire life, a female is born with the maximum number of primary oocytes she will ever produce.

Oogenesis is the process of ovum formation. At the onset of puberty, some primary oocytes are stimulated to continue meiosis (see Figure 31-2). When a primary oocyte divides, it produces one *polar body* (a nonfunctional cell) and a *secondary oocyte*. The secondary oocyte is released from an ovary each month during a process called **ovulation**. When the secondary oocyte is fertilized, it divides to form a mature, fertilized ovum. Therefore, the process of meiosis begins before a

female is born and is completed only if a secondary oocyte is fertilized. The mature ovum contains 23 chromosomes; when it combines with a sperm cell, the resulting cell contains 46 chromosomes.

Internal Accessory Organs of the Female Reproductive System

The female reproductive internal accessory organs are the fallopian tubes, uterus, and vagina.

Fallopian Tubes A fallopian tube, or *oviduct*, opens near each ovary, and the other end connects to the uterus. The fringed, expanded end of a fallopian tube near an ovary is called an **infundibulum**. The infundibulum ends in *fimbriae*, or finger-like projections. The infundibulum and its fimbriae “catch” an ovum as it leaves an ovary. Fallopian tubes are muscular tubes that are lined with mucous membrane and cilia. This construction allows the tube to propel the ovum toward the uterus using peristalsis and the sweeping motions of cilia.

Uterus The uterus is a hollow, muscular organ that receives a developing embryo and sustains its development. The upper, domed portion of the uterus is called the *fundus*, the main portion is called the *body*, and the narrow, lower portion that extends into the vagina is called the *cervix*. The opening of the cervix is called the *cervical orifice*.

FIGURE 31-4 Sagittal view of female reproductive organs. The female reproductive system produces ova for fertilization and provides the place and means for a fertilized ovum to develop.

FIGURE 31-5 Anterior view of internal female reproductive organs, showing ovulation of an oocyte.

The wall of the uterus has three layers: the endometrium, myometrium, and perimetrium. The *endometrium* is the innermost lining of the uterus. It is vascular with a rich blood supply, and it contains numerous tubular glands that secrete mucus. The *myometrium* is the middle, thick, muscular layer. The *perimetrium* is a thin layer that covers the myometrium. It secretes serous fluid that coats and protects the uterus.

Vagina The vagina is a tubular, muscular organ that extends from the uterus to the outside of the body. The muscular folds of the vagina, called *rugae*, allow it to expand to receive an erect penis during sexual intercourse and to provide a passageway for delivery of offspring as well as for uterine secretions. The opening of the vagina is posterior to the urinary opening and anterior to the anal opening. The wall of the vagina has three layers: an innermost, mucosal layer that secretes mucus; a middle, muscular layer; and an outermost, fibrous layer. The opening of the vagina to the outside is known as the *vaginal os*, the *vaginal orifice*, or the *vaginal introitus*.

External Accessory Organs of the Female Reproductive System

Mammary glands are accessory organs of the female reproductive and integumentary systems (see Figure 31-6). Their reproductive function is the secretion of milk for newborn offspring.

Mammary glands are located beneath the skin in the breast area. A nipple is near the center of each breast. The pigmented

area that surrounds the nipple is called the *areola*. Each gland is made of 15 to 20 lobes and contains *alveolar glands* that make milk under the influence of the hormone *prolactin*. The hormone *oxytocin (OT)* induces *lactiferous ducts* to deliver milk through openings in the nipples. If a woman wants to breast-feed, she must produce adequate amounts of prolactin and oxytocin.

External Genitalia of the Female Reproductive System

The female external genitalia, collectively known as the *vulva*, include the following structures: mons pubis, labia majora, labia minora, clitoris, urethral meatus, vaginal orifice, Bartholin's glands, and perineum.

Labia Majora The labia majora are rounded folds of adipose tissue and skin that protect the other external female reproductive organs. At their anterior ends, the labia majora form the *mons pubis*, which is a fatty area that overlies the symphysis pubis. The labia majora and mons pubis are typically covered in pubic hair in postpubescent females.

Labia Minora The labia minora are folds of skin between the labia majora. They are pinkish in color because of their high degree of vascularity. They merge together anteriorly to form a hood over the clitoris.

The space enclosed by the labia minora is called the *vestibule*. The **Bartholin's glands**, sometimes referred to as the *vestibular glands*, secrete mucus into this area during

FIGURE 31-6 Mammary glands: (a) sagittal view and (b) anterior view.

sexual arousal. This mucus eases insertion of the penis into the vagina.

Clitoris The clitoris is anterior to the urethral meatus. It contains the female erectile tissue and is rich in sensory nerves.

Perineum The perineum is the area between the vagina and the anus. This is the area that is sometimes “clipped” during the birth process, in a procedure known as an *episiotomy*.

Erection, Lubrication, and Orgasm

During sexual arousal, nervous stimulation causes the clitoris to become erect and the Bartholin’s glands to become active. At the same time, the vagina elongates. If the clitoris is sufficiently stimulated, an orgasm occurs. During orgasm, the walls of the uterus and fallopian tubes contract to help propel sperm toward the upper ends of the fallopian tubes.

Female Reproductive Hormones

Beginning at puberty, the hypothalamus secretes increasing amounts of GnRH. This causes the anterior pituitary gland to release FSH and LH, which stimulate the ovary to produce estrogen and progesterone, as well as to mature the ovarian follicles. The estrogen and progesterone are responsible for the female secondary sex characteristics: breast development, increased vascularization of the skin, and increased fat deposits in the breasts, thighs, and hips.

Female Reproductive Cycle

The female reproductive cycle is also called the *menstrual cycle*. See Figure 31-7. It consists of regular changes in the uterine lining that leads to a monthly “period,” or shedding of the uterine lining, along with bleeding. The first menstrual period is known as **menarche**. **Menopause** is the termination of the menstrual cycle because of normal aging of the ovaries. The following steps are the major hormonal changes that occur during one reproductive cycle:

1. The anterior pituitary gland releases FSH, which stimulates an ovarian follicle to mature.
2. The maturing follicle secretes estrogen. Estrogen causes the uterine lining to thicken.
3. The anterior pituitary gland releases a sudden surge of LH, which triggers ovulation.
4. Following ovulation, follicular cells of the follicle become a *corpus luteum*.
5. The corpus luteum secretes progesterone, which causes the uterine lining to become more vascular and glandular.
6. If the released oocyte is not fertilized, the corpus luteum degenerates, causing estrogen and progesterone levels to fall.
7. The decline in estrogen and progesterone levels causes the uterine lining to break down, and menses (elimination of the uterine lining, with bleeding) starts.
8. When the anterior pituitary releases FSH, the reproductive cycle begins again.

FIGURE 31-7 A typical 28-day menstrual cycle.

PATHOPHYSIOLOGY

LO 31.4

Common Diseases and Disorders of the Female Reproductive System

BREAST CANCER, according to the American Cancer Society, is the second leading cause of cancer deaths in women after lung cancer. Depending on tumor size and how far cancer cells have spread, breast cancer is classified in stages from 0 to 4, with stage 4 cancer being the most serious. Early diagnosis through regular mammograms and breast self-exams greatly increases the success of treatment. Teaching female patients about breast self-exam and its importance in the early detection of breast cancer is an important aspect of being a medical assistant. You will learn how to teach women this technique in the *Assisting in Reproductive and Urinary Specialties* chapter.

Causes. The causes are largely unknown, although breast cancer may be related to hormonal changes or the presence of certain genes.

Signs and Symptoms. Signs and symptoms include a lump in the breast that is usually painless and firm, a lump in the armpit, discharge from the nipples, dimpled skin on the breast or nipple, and breast pain. Swelling of the breast into the adjacent arm and bone pain may be present in advanced cases. Inflammatory breast cancer may present only as a painless rash of the affected breast with none of the other typical symptoms.

Treatment. Nonsurgical treatment methods include hormone therapy, radiation therapy, and chemotherapy. Surgical options include surgery to remove affected lymph nodes, lumpectomy

(surgery to remove a lump), and mastectomy (surgery to remove a breast).

CERVICAL CANCER generally develops slowly, although adenocarcinoma of the cervix, which tends to be a more rapidly spreading cancer, is the exception to this rule. With early detection by a yearly Pap smear (a test looking for abnormal cervical cells), treatment is often successful. Note that the new recommendation for Pap smear screenings is now every other year if a woman's previous screenings have been negative for 5 years and if the woman is in a monogamous relationship and not on birth control pills.

Causes. A weak immune system may be a factor in the development of this cancer. Risk factors also include sexual intercourse early in life, multiple sexual partners, and infection with the human papillomavirus (HPV).

Signs and Symptoms. Primary symptoms include frequent vaginal discharge, sporadic vaginal bleeding, vaginal bleeding after sexual intercourse, and abnormal cells in the cervix. Patients who are in later stages of this disease may experience pain in the pelvic area or legs, or bone fractures.

Treatment. Radiation therapy, chemotherapy, the removal or destruction of diseased tissue with cryosurgery or laser

surgery, and the removal of the uterus (hysterectomy) are the treatments for this disease.

CERVICITIS is an inflammation of the cervix, which is usually caused by an infection.

Causes. Causes include bacterial or viral infections and allergic reactions to spermicidal creams and latex condoms.

Signs and Symptoms. Frequent vaginal discharge, pain during intercourse, and vaginal bleeding after intercourse are common signs and symptoms.

Treatment. This condition is treated with antibiotics and by changing the contraception method.

DYSMENORRHEA is the condition of experiencing severe menstrual cramps that limit normal daily activities.

Causes. Causes include anxiety, endometriosis, pelvic inflammatory disease (PID), fibroid tumors in the uterus, ovarian cysts, abnormally high levels of prostaglandins, and multiple sexual partners.

Signs and Symptoms. Common symptoms are abdominal pain, including sharp or dull pain in the pelvic area just prior to and during the menstrual period.

Treatment. Nonsurgical treatments include pain medication, anti-inflammatory drugs, medications that inhibit prostaglandin formation, oral contraceptives, and antibiotics in the case of PID. Surgical treatments include hysterectomy and surgery to remove cysts or fibroids.

ENDOMETRIOSIS is a condition in which tissues that make up the lining of the uterus grow outside the uterus.

Causes. The cause of this disorder is unknown; it may be inherited.

Signs and Symptoms. Signs and symptoms include infertility, heavy bleeding from the uterus, pain in the abdomen or pelvis, painful periods, spotting between periods, and pain during sexual intercourse.

Treatment. Oral contraceptives, pain medications, and various hormone therapies may be prescribed. Surgical treatments include laser surgery to remove endometrial tissue outside the uterus and hysterectomy.

FIBROCYSTIC BREAST DISEASE is the presence of abnormal cystic tissues in the breasts. The cysts vary in size related to the menstrual cycle. It is a common disorder and occurs in more than 60% of women in the United States between age 30 and 50. It is rare in women who have gone through menopause because it is related to hormonal changes occurring during the menstrual cycle. It is important to note that fibrocystic breast disease is not considered to put a woman at higher risk of breast cancer.

Causes. This disorder is caused by hormonal changes associated with the menstrual cycle and ingestion of various dietary substances, including caffeine, nicotine, and sugar. Birth control pills may also aggravate this condition.

Signs and Symptoms. Common symptoms include breasts that feel “lumpy,” breast tenderness or pain, itchy nipples, and dense tissues as seen in a mammogram.

Treatment. Treatments include changing one’s diet and taking supplements such as vitamin E, B complex, and magnesium. Wearing support bras may help with pain control.

UTERINE FIBROIDS are benign (noncancerous) tumors that grow in the uterine wall. They are known to affect one out of four women in their thirties and forties and appear to be more common in women of African descent.

Causes. The causes are mostly unknown, although it has been found that the tumors enlarge as estrogen levels increase. Heredity appears to play a role.

Signs and Symptoms. The signs and symptoms are pressure in the abdomen, severe menstrual cramps, abdominal gas, heavy menstrual bleeding, and intermenstrual bleeding. Back and leg pain may also occur.

Treatment. Treatment includes pain medications, hormone treatments to shrink tumors, surgery to remove tumors, hysterectomy, and surgery to decrease the blood supply to the uterus.

OVARIAN CANCER is considered more deadly than other types of cancer because its signs and symptoms are usually mild or indistinct until the disease has spread to other organs, making early detection difficult. Current statistics suggest that about 1 woman in 67 will develop ovarian cancer. Women with a family history of ovarian cancer may be counseled to consider prophylactic *oophorosalphingectomy* (removal of the ovaries and fallopian tubes) prior to actually developing ovarian cancer.

Causes. The causes are unknown, although the presence of certain genes has been indicated as a risk factor. Some oral contraceptives may lower the risk of developing this disease.

Signs and Symptoms. Abdominal and pelvic discomfort, unusual menstrual cycles, indigestion, bloating, nausea, and excessive hair growth are signs and symptoms. Diagnosis is made after ultrasound, a CA-125 blood test, and an ovarian biopsy.

Treatment. Treatment options include radiation therapy, chemotherapy, and surgery to remove the ovaries and reproductive organs.

PREMENSTRUAL SYNDROME (PMS) is a collection of symptoms that occur just before a menstrual period.

Causes. The causes are mostly unknown, although hormone fluctuations during the menstrual cycle are implicated.

Signs and Symptoms. The signs and symptoms include anxiety, depression, irritability, acne, fatigue, food cravings, bloating, aches in the head or back, abdominal pain, breast tenderness, muscle spasms, diarrhea, weight gain, and loss of sex drive.

Treatment. PMS is commonly treated with pain medications, diuretics, medications to treat depression or anxiety, and oral contraceptives. Many women have also found changes in diet to be helpful, including limiting caffeine, sugar, and sodium. The addition of B complex vitamins may also be helpful.

UTERINE (ENDOMETRIAL) CANCER is most common in postmenopausal women. In the United States, it accounts for approximately 6% of cancer deaths in women.

Causes. The causes are mostly unknown, although it may be related to increased levels of estrogen.

Signs and Symptoms. Signs and symptoms include abdominal pain; abnormal bleeding from the uterus; pelvic pain; and a thin, white vaginal discharge in postmenopausal women.

Treatment. Treatment includes radiation therapy, chemotherapy, and surgery to remove the uterus, fallopian tubes, and ovaries.

VULVOVAGINITIS (inflammation of the vulva and vagina) and **VAGINITIS** (inflammation of the vagina) are usually associated with an abnormal vaginal discharge. Some vaginal discharge is normal for all women, and it varies throughout the menstrual cycle. Normal vaginal discharge is clear, whitish, or yellowish in color.

Causes. This condition can be caused by yeast infections, tampon use, poor hygiene, bacteria, antibiotics, and sexually transmitted infections (STIs). Vaginitis may be prevented through good hygiene and safe sex practices.

Signs and Symptoms. Common symptoms include fever, vulvar and vaginal itching and swelling, an abnormal increase or decrease in the amount of vaginal discharge, an abnormal color of vaginal discharge (brown, green, or pinkish), a change in the consistency of vaginal discharge (frothy or cheese-like), and vaginal discharge that has an abnormal odor.

Treatment. The patient may be given medications for fungal or bacterial infections, or the patient and her sexual partner may be treated for STIs.

► Pregnancy

LO 31.5

Pregnancy is defined as the condition of having a developing offspring in the uterus. Pregnancy results when a sperm cell unites with an ovum in a process called fertilization (see Figure 31-8).

Fertilization

Prior to fertilization, an ovum is released from an ovary and travels through a fallopian tube. During sexual intercourse, the male deposits semen into the vagina. Sperm cells must travel up through the uterus to the fallopian tubes to fertilize the ovum.

Prostaglandins in semen stimulate the flagella of sperm cells to undulate, causing the swimming action of sperm. Prostaglandins also stimulate muscles in the uterus and fallopian tubes to contract. These contractions (peristalsis) help the sperm reach the ovum. Normally about 10 to 14 days after ovulation, high estrogen levels stimulate the uterus and cervix to secrete a thin, watery fluid that also promotes the movement of sperm toward the ovum.

Although many sperm cells normally reach an ovum, only one sperm cell unites with the ovum, penetrating the follicular cells and a layer called the *zona pellucida*, which surrounds the cell membrane of the ovum. The acrosome of this sperm releases enzymes to help the sperm penetrate the membrane

FIGURE 31-8 Stages of early embryo development.

of the ovum. Once a sperm unites with an ovum, the ovum releases enzymes to prevent other sperm from invading it. The enzymes cause the zona pellucida to become hard and therefore impenetrable to other sperm.

The nucleus of the ovum (with 23 chromosomes) and the nucleus of the sperm (with 23 chromosomes) fuse together to make one nucleus that contains 46 chromosomes. The cell that is formed by this union is called a **zygote**.

The Prenatal Period

The prenatal period is the time before the offspring is born. It is divided into an *embryonic period* (weeks 2 through 8 of pregnancy) and a *fetal period* (week 9 to the delivery of the offspring). It is further divided into three periods known as trimesters, which consist of 3 calendar months each. See *Points on Practice: The Pregnant Patient*.

About 1 day after the zygote forms, it begins to undergo mitosis at a relatively rapid rate. This rapid cell division is called *cleavage*, and the resulting ball of cells is called a *morula*. The morula travels down the fallopian tube to the uterus. Fluid then invades the morula, and this organism is called a **blastocyst**. The blastocyst implants in the endometrial wall of the uterus. The process of moving from zygote formation to implantation of the blastocyst takes about 1 week. Once the blastocyst implants, a group of cells in the blastocyst, called the *inner cell mass*, gives rise to an **embryo**. Other cells in the blastocyst, along with cells of the uterus, eventually form the **placenta**.

The Embryonic Period The embryonic period extends from the second week of pregnancy to the end of the eighth week of development. During this stage, the placenta, *amnion*, *umbilical cord*, and *yolk sac* form, along with most of the internal organs and external structures of the embryo (see Figure 31-9). The cells of the inner cell mass organize into

layers called **primary germ layers**. All organs are formed from the primary germ layers, which include the ectoderm, mesoderm, and endoderm.

- The *ectoderm* develops into nervous tissue and some epithelial tissue.
- The *mesoderm*, the middle layer, develops into connective tissues and some epithelial tissue.
- The *endoderm* develops into epithelial tissues only.

The placenta allows nutrients and oxygen from maternal blood to pass to embryonic blood. It also allows waste products from the fetal blood to pass into maternal blood. The **amnion** is a protective, fluid-filled sac that surrounds the embryo. The *umbilical cord* contains three blood vessels—one umbilical vein that carries oxygenated blood from the placenta to the embryo, and two umbilical arteries that carry deoxygenated blood from the embryo back to the placenta.

The yolk sac makes new blood cells for the fetus, as well as cells that eventually become the sex cells of the baby. By the end of the embryonic stage, the baby closely resembles a human because all external structures (arms, hands, legs, feet, etc.) have formed.

The Fetal Period The fetal period begins at the end of the eighth week of development and ends at birth. During this period, the growth of the offspring, which is now called a **fetus**, is rapid. By the twelfth week, bones have begun to harden and the external reproductive organs are distinguishable as male or female.

The growth rate of the fetus slows down in the fifth month but skeletal muscles become active. In the sixth month, the fetus starts to gain substantial weight. In the seventh month, the eyelids open. In the last 3 months of pregnancy, fetal brain cells divide rapidly and organs continue to grow. The testes of the male descend into the scrotum. The last organ systems to

FIGURE 31-9 Primary germ layers and membranes associated with an embryo.

completely develop are the digestive and respiratory systems. By the end of the ninth month, the fetus is usually positioned upside down in the uterus in preparation for delivery.

Fetal Circulation

Throughout prenatal development, the placenta and umbilical blood vessels carry out the exchange of nutrients, oxygen, and waste products between maternal and fetal blood. Therefore, the fetus does not need to send blood to the lungs to pick up oxygen, nor does it need to send blood to the liver to process nutrients.

Fetal circulation has some important differences from normal circulation, which are illustrated in Figure 31-10. In the adult heart, blood flows from the right atrium into the right ventricle so that it can be pumped to the lungs. In the fetal heart, a hole called the **foramen ovale** is located between the right and left atria. This hole allows most of the fetal blood to flow from the right atrium into the left atrium. However, some fetal blood does flow from the right atrium into the right ventricle, and the right ventricle then delivers the blood to the pulmonary trunk.

In the fetus, there is also a connection between the pulmonary trunk and the aorta called the **ductus arteriosus**. This connection allows blood to flow from the pulmonary trunk into the aorta. In the adult, this connection closes and blood flows from the pulmonary trunk to the lungs. The fetus also contains a blood vessel called the **ductus venosus** that allows most of the blood to bypass the liver. After a baby is born, the foramen ovale, ductus arteriosus, and ductus venosus normally close.

Hemoglobin within the fetus has a much higher affinity for oxygen than does the normal hemoglobin that is found after birth and during growth. Therefore, the fetus's blood is adapted to carry more oxygen.

Hormonal Changes During Pregnancy

Many hormonal changes take place when a woman is pregnant. Following implantation of the embryo, the embryo cells

begin to secrete *human chorionic gonadotropin (HCG)*. HCG maintains the corpus luteum in the ovary so it will continue to secrete estrogen and progesterone. The placenta also secretes large amounts of progesterone and estrogen.

Progesterone and estrogen stimulate the uterine lining to thicken and inhibit the anterior pituitary gland from secreting FSH and LH to prevent ovulation during pregnancy. Estrogen and progesterone also stimulate the development of the mammary glands, inhibit uterine contractions, and stimulate the enlargement of female reproductive organs.

A hormone called *relaxin*, which comes from the corpus luteum, inhibits uterine contractions and relaxes the ligaments of the pelvis in preparation for childbirth. The placenta also secretes *lactogen*, a hormone that stimulates the enlargement of mammary glands. *Aldosterone*, which is secreted from the adrenal gland, increases sodium and water retention. The secretion of *parathyroid hormone (PTH)* increases, helping to maintain high calcium levels in the blood.

► The Birth Process

LO 31.6

The birth process ends pregnancy. This process begins when progesterone levels fall. When this happens, uterine contractions are no longer inhibited and the uterus secretes prostaglandins that stimulate uterine contractions, which cause the posterior pituitary gland to release oxytocin. Oxytocin stimulates stronger uterine contractions until the birth process ends. The birth process itself occurs in three stages after the fetus settles into position in the mother's pelvis (see Figure 31-11a).

1. *Dilation* (see Figure 31-11b). The cervix thins and softens, known as *effacement*, dilating to approximately 10 cm. Regular contractions occur at this stage and the amniotic sac ruptures. If rupture does not occur, the sac may be surgically punctured. This stage normally lasts 8 to 24 hours.

POINTS ON PRACTICE

The Pregnant Patient

The pregnant patient goes through three distinct stages known as *trimesters*. Each trimester has specific events associated with it.

First Trimester

The first trimester is from week 1 to week 12. During weeks 1 to 8 the product of conception is an embryo; after week 8 it is a fetus. Week 12 marks the end of the first trimester, or one-third of the pregnancy. It is usually during the first trimester that women confirm they are pregnant. "Morning sickness" commonly occurs during this stage.

Second Trimester

Fine, soft hair (lanugo) appears on the shoulders, back, and head of the fetus during the fourth month. By the 20th week,

fetal movement may be felt, and the pregnant woman begins to show fullness in the abdomen. Identifiable periods of fetal sleep and wakefulness occur as the second trimester ends at the completion of the sixth month.

Third Trimester

The last trimester encompasses the most noticeable period of growth, both in the fetus and in the mother. By the end of 30 weeks, the fetus most likely has assumed a head-down position and has a 50% chance of survival if it is born at this time. The fetus is said to have come full term after it is approximately 9 months (40 weeks) old.

More information about caring for a pregnant patient is found in the *Assisting with Reproductive and Urinary Specialties* chapter.

FIGURE 31-10 Fetal circulation.

2. *Expulsion* (see Figure 31-11c). Also known as *parturition*, this is the actual childbirth stage. Forceful contractions and abdominal compressions force the fetus from the uterus into the vagina. This stage may take 30 minutes or only a few minutes.
3. *Placental stage* (see Figure 31-11d). This stage is also referred to as the *afterbirth*. Approximately 10 to 15 minutes after the birth, the placenta separates from the uterine wall and is expelled. Uterine contractions continue during this stage and the blood vessels constrict to prevent hemorrhage. Normal blood loss is less than 350 mL (12 oz).

If the fetus is not in the usual head-down position, the child is said to be *breech*, in which the buttocks or feet present first. If the fetus cannot be turned manually, forceps may be used to assist in the birth. Alternately, a *cesarean section* (C-section) may be performed to deliver the infant through the abdominal wall.

At 1 minute and 5 minutes after the baby is born, an **APGAR** test is performed to determine how well the baby is breathing and how well the heart is working. The test has five categories: respiratory effort, heart rate, skin color, reflexes, and muscle tone. In each category, the baby is given a score of 0, 1, or 2, with 2 being the best score. Table 31-1 shows how the scores are applied. The individual scores are added together to provide the APGAR score. A score of 7 to 9 is considered normal. Babies rarely score a 10 because their extremities are normally blue immediately after birth. An APGAR score below 7 indicates that the baby may need medical support, such as supplemental oxygen or physical stimulation.

The Postnatal Period

The *postnatal period* is the 6-week period following birth. The first 4 weeks of the postnatal period are called the *neonatal period* and the offspring is called a *neonate*. The neonatal

FIGURE 31-11 Stages of the birth process: (a) the fetal position before birth, (b) dilation of the cervix, (c) delivery of the fetus, and (d) delivery of the placenta.

TABLE 31-1 APGAR Scores

	0	1	2
Respiratory Effort	Baby is not breathing.	Baby is breathing, but breaths are slow or irregular.	Baby is breathing well enough to cry successfully.
Heart Rate	Baby's heart is not beating.	Heart rate is less than 100 beats per minute.	Heart rate is 100 beats per minute or greater.
Skin Color	The skin is cyanotic (pale blue).	The skin is pink except in the extremities, which are cyanotic.	The skin is entirely pink.
Reflexes	Baby does not respond to stimulation such as a light pinch.	Baby grimaces in response to stimulation.	Baby grimaces and sneezes, coughs, or cries in response to stimulation.
Muscle Tone	Muscles are flabby or loose.	Muscles have some muscle tone.	The baby actively moves.

period is marked by adjustment to life outside the uterus. The lungs of the neonate must expand, which is why the baby's first breath is forceful. The newborn's liver is immature, so the baby must obtain most of its glucose from fat stores in the skin. The newborn urinates a lot because the kidneys are too immature to concentrate urine well. In addition, body temperature tends to be unstable. The newborn's umbilical vessels constrict, and the foramen ovale, ductus arteriosus, and ductus venosus close.

Milk Production and Secretion

After childbirth, prolactin causes the mammary glands to produce milk. The hormone oxytocin stimulates the ejection of milk from mammary gland ducts. As long as milk is removed from the mammary glands, milk production continues. Once a female stops breast-feeding, the hypothalamus inhibits the release of prolactin and oxytocin, and milk production stops.

Contraception

LO 31.7

Birth control methods, also referred to as *contraception*, reduce the risk of pregnancy (see Figure 31-12). Although many birth control methods are available, some are more

FIGURE 31-12 Couples use various forms of contraception. To provide adequate patient teaching, you should be knowledgeable of these methods.

© Peter Ardito/Getty Images

reliable than others. The following are the most commonly used birth control methods:

- **Coitus interruptus (withdrawal).** The male physically withdraws the penis from the vagina before ejaculation. This method is not reliable because small amounts of semen may enter the vagina before ejaculation.
- **Rhythm method (periodic abstinence).** This method requires abstinence from sexual intercourse around the time a female is ovulating. However, predicting ovulation can be difficult; therefore, this type of contraception can be unreliable.
- **Mechanical barriers.** Mechanical barriers prevent sperm from entering the female reproductive tract. They include condoms, diaphragms, and cervical caps. Spermicides are often used in conjunction with barrier methods, particularly condoms and diaphragms.
- **Chemical barriers.** Chemical barriers destroy sperm in the female reproductive tract. They primarily include spermicides.

- **Oral contraceptives.** Birth control pills are oral contraceptives. They normally include low doses of estrogen or progesterone that prevent the LH surge necessary for ovulation. These pills therefore prevent ovulation. Newer oral contraceptives have been developed in which the woman takes the pill daily for 3 months and then is off for 1 week, so that a period occurs only four times a year.
- **Injectable contraceptives.** Depo-Provera® is one brand of injectable contraceptive. It prevents ovulation and alters the lining of the uterus so that implantation of a blastocyst is not likely.
- **Insertable contraceptives.** NuvaRing® is one of the newest forms of contraception. The woman inserts the ring vaginally and leaves it in for 3 weeks. She removes the ring at the beginning of the fourth week to allow for menstruation on the same schedule she would experience using most oral contraceptives. However, this method has been associated with increased chances for blood clots, stroke, and heart attack, especially in women who smoke.
- **Contraceptive implants.** Contraceptive implants are small rods of progesterone that are implanted beneath the skin to prevent ovulation.
- **Transdermal contraceptives.** Commonly called “the patch,” transdermal contraceptives are applied to the skin once a week and removed on the seventh day for a 3-week cycle. No patch is applied during the fourth week to allow for the menstrual period.
- **Intrauterine devices.** An intrauterine device (IUD) is a small, solid device that a licensed practitioner places in the uterus. It prevents the implantation of a blastocyst.
- **Surgical methods.** *Tubal ligation* is a surgical method used in females to prevent pregnancy. In this process, each fallopian tube is cut and tied to prevent sperm from reaching the oocyte. *Vasectomy* is a surgical method used in males to prevent pregnancy. In this process, each vas deferens is cut and tied to prevent sperm from being ejaculated. Figure 31-13 illustrates these birth control methods.

FIGURE 31-13 (a) Tubal ligation involves cutting and ligating each fallopian tube. (b) Vasectomy involves cutting and ligating the vas deferens.

► Infertility

LO 31.8

Infertility is the inability to conceive a child. A couple that has never been pregnant and has tried for 12 months to achieve pregnancy is said to have *primary infertility*. If a couple has had at least one pregnancy but has not been able to get pregnant again after 1 year, they are said to have *secondary infertility*.

In the United States, about 15% of infertility causes are unknown, about 35% are the result of problems in the male, and about 50% are because of problems in the female. Common causes of infertility as a result of male factors include the following:

- Impotence
- Retrograde ejaculation
- Low or absent sperm count
- Use of various medications or drugs
- Decreased testosterone production
- Scarring of the male reproductive tract from STIs
- Previous mumps infection that infected the testes
- Inflammation of the epididymis or testes

Infertility because of female factors includes these common causes:

- Scarring of fallopian tubes from sexually transmitted infections (STIs)
- Pelvic inflammatory disease (PID)
- Inadequate diet
- Lack of ovulation
- Lack of menstrual cycles
- Endometriosis
- Abnormal shape of the uterus or cervix
- Hormone imbalances
- Cysts in ovaries
- Being older than age 40

Women are most likely to get pregnant in their early twenties. By the time a woman reaches age 40, her chance of conceiving a child is less than 10% each month. In general, infertility in men is not age related.

Infertility Tests

A number of tests are used to diagnose infertility. They include the following:

- Semen analysis. This test determines the semen thickness and the number and motility of sperm cells in a sample.
- Monitoring morning body temperature. If a woman's body temperature does not rise slightly once a month, which is best determined by taking her temperature first thing in the morning, she may not be ovulating.
- Blood hormone measurements. In females, various hormone levels can be monitored to predict ovulation and the general health of the ovaries. In males, testosterone levels are measured.
- Endometrial biopsy. This test determines the health of the uterine lining.
- Urinary analysis for luteinizing hormone. The absence of this hormone in urine may indicate a lack of ovulation.
- Hysterosalpingogram. This type of X-ray uses contrast media to visualize the shape of the uterus and the fallopian tubes. If a woman has excess scar tissue in her fallopian tubes, the contrast cannot run through them.
- Laparoscopy. Laparoscopy is a procedure used to visualize pelvic organs.

Treatment of Infertility

Many treatments are available for infertility, but often there is no cure for this condition. Common treatments include surgery to repair abnormal or scarred fallopian tubes, fertility drugs to increase ovulation, and hormone therapies. When infertility cannot be cured, procedures such as artificial insemination, in vitro fertilization, or the use of a surrogate may help a couple to have a child.

PATHOPHYSIOLOGY

LO 31.9

Sexually Transmitted Infections Occurring in Both Sexes

AIDS (ACQUIRED IMMUNODEFICIENCY SYNDROME) is covered in detail in the *Microbiology and Disease* chapter.

Causes. The human immunodeficiency virus (HIV) causes AIDS.

Signs and Symptoms. These are numerous and include decreased T-cell count; flu-like symptoms; and a host of opportunistic infections, including *Pneumocystis carinii* pneumonia (PCP), Kaposi's sarcoma (KS), and cytomegalovirus (CMV).

Treatment. Antiviral medications have been successful in decreasing the viral load and maintaining T-cell counts in some patients, but there are many side effects to these drugs, and

they require a strict medicine regime. Other treatments include drugs to support the immune system and to treat opportunistic infections as they arise.

CHLAMYDIA is the most commonly reported STI in the United States. Chlamydia may be grossly underreported because, for women, there are often no symptoms until the disease has spread.

Causes. Chlamydia is caused by the bacterium *Chlamydia trachomatis*.

Signs and Symptoms. For females, there may be no symptoms. If they do occur, it will be 2 to 3 weeks after exposure. Symptoms may include abnormal vaginal discharge and burning on urination. As the disease progresses to other reproductive organs, pelvic inflammatory disease (PID) occurs and can cause abdominal pain, pain during intercourse, and

intermenstrual bleeding. Men may have a penile discharge and pain on urination. In women, PID is a common cause of infertility; men seldom have serious complications related to chlamydia.

Treatment. Both partners must be treated to avoid reinfection. Effective antibiotics against chlamydia include azithromycin and doxycycline. Patients must complete the medication cycle and avoid sexual contact until both partners are cured. Because of the high rate of reinfection, women should be retested 3 to 4 months after treatment.

GENITAL WARTS, also known as *Condyloma acuminata*, are one of the most common STIs in the world affecting both men and women. The virus that causes genital warts has been implicated in an increased risk of cervical cancer in women.

Causes. Human papillomavirus (HPV) is the cause of genital warts.

Signs and Symptoms. Not everyone infected with HPV has symptoms. Genital warts may appear weeks or months after infection in the vulva, vagina, and cervix in women. In men, warts appear on the scrotum and penis. They have also been known to appear around the anus and on the thighs and groin. It is important to note that HPV can be spread even if the patient has no outward signs of the disease.

Treatment. Imiquimod cream, 20% podophyllin anti-mitotic solutions, and TCA (trichloroacetic acid) may be used to remove warts. Cryosurgery, cautery, and laser surgery may also be used; however, the virus remains in the patient's body. Currently, there is no treatment to rid the body of the virus. Vaccines to prevent infection with some strains of HPV have been approved by the FDA and are considered highly effective.

GONORRHEA is a bacterial STI that is common in the United States. The Centers for Disease Control and Prevention (CDC) estimates 700,000 new infections per year.

Causes. Gonorrhea is caused by *Neisseria gonorrhoea*, a bacterium that thrives in the warm, moist areas of the reproductive tract, urethral tract, mouth, throat, eyes, and anus.

Signs and Symptoms. Men often have no symptoms. If they do appear, it will be 2 to 3 days after exposure, when the patient will experience burning on urination and/or white, yellow, or greenish penile discharge. Women may also be asymptomatic, but common symptoms include dysuria, increased vaginal discharge, and intermenstrual bleeding. Gonorrheal infections, like chlamydia, may lead to PID in women. In men, it may lead to epididymitis.

Treatment. Antibiotics are effective against gonorrhea, and both partners must be treated. However, drug-resistant strains of gonorrhea are developing, making successful treatment more difficult. It is not unusual for a patient with gonorrhea to also be diagnosed with chlamydia or other STIs, which also need to be tested for and treated if found to be present. In addition, gonorrhea lives well and actively in the throat, even if there is not an active genitourinary infection, which can lead to additional co-infection.

HERPES SIMPLEX infections include those caused by both herpes simplex 1 and herpes simplex 2.

Causes. Herpes viruses cause both infections. In most cases, herpes simplex 1 causes oral blisters known as cold sores, and herpes simplex 2 causes what is commonly known as genital herpes, although herpes simplex 1 has also been known to cause the genital type of infection. The herpes infection may also be passed from an infected mother to her child during pregnancy and birth with potentially fatal outcomes.

Signs and Symptoms. Many infected persons, both male and female, have minimal or no symptoms. Typical symptoms of genital herpes include blisters on or around the genitals or rectum. These blisters break, leaving tender ulcers in their wake for 2 to 4 weeks. The number and severity of outbreaks tend to decrease over a period of years.

Treatment. There is no treatment to rid the patient of the herpes virus; however, antiviral medications such as acyclovir may shorten outbreaks when they occur. Daily suppressive therapies with medications like Valtrex® may reduce the risk of transmission. Pregnant women with active outbreaks should deliver the child via a C-section.

PUBIC LICE are known commonly as *crabs* and medically known as *Pediculosis pubis*.

Causes. Pubic lice are caused by a parasitic infestation in the genital area, most commonly spread through sexual contact.

Signs and Symptoms. Symptoms include itching in the genital area with visible evidence of eggs known as *nits*, as well as crawling lice. Lice only live while on a human body. If they fall off the body, they will die in 24 to 48 hours.

Treatment. Patients should use a lice-killing shampoo of 1% permethrin or pyrethrin. All laundry and clothing must be washed in hot water and dried using the hot dryer cycle for at least 30 minutes. Nits remaining in hair may be removed by hand. All partners should be treated and sexual contact should be avoided until treatment is completed.

SYPHILIS is the one bacterial STI whose incidence in women is decreasing, according to the CDC. However, it is increasing in males, especially in those who have sex with other males.

Causes. Syphilis is caused by the bacterium *Treponema pallidum*.

Signs and Symptoms. Primary-stage syphilis usually involves the appearance of a painless sore known as a *chancre*, which appears 10 to 90 days after exposure. It remains for 3 to 6 weeks, disappearing even without treatment. If untreated, the disease lies dormant, progressing to the second stage, which is characterized by a nonpruritic rash and lesions in the mucous membranes. The rash may be associated with flu-like symptoms. Again, all symptoms disappear without treatment. After a long latent period without symptoms, often years later, the third stage becomes apparent, with damage to the brain, eyes, heart, blood vessels, liver, and bones. This damage may lead to muscular incoordination, paralysis, numbness, blindness, dementia, and, finally, death.

Treatment. The cure for syphilis in its early stage is a single dose of intramuscular penicillin. Additional doses are needed for disease present longer than a year. Other antibiotics are also effective for patients allergic to penicillin. The patient must avoid sexual contact until treatment is completed to avoid further spread of the disease.

TRICHOMONIASIS (also known as *trichomonas* infection or the abbreviation *trich*) is a common, curable STI.

Causes. Trichomoniasis is caused by the protozoan parasite *Trichomonas vaginalis*.

Signs and Symptoms. The vagina is the most common site of infection for females; the urethra is the most common site for males. Male patients may have penile irritation, dysuria, or a mild penile discharge, but more often than not, men have no symptoms. Females often have a frothy, yellow-green vaginal discharge with a strong “fishy” odor to it. Itching and irritation of the vulva are also common.

Treatment. Oral metronidazole (Flagyl®) is the treatment of choice. Both partners, even those who are asymptomatic, must be treated to avoid reinfection. Sexual contact should be avoided until after treatment is completed.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
31.1 Summarize the organs of the male reproductive system, including the locations, structures, and functions of each.	The organs of the male reproductive system include the testes, responsible for sperm and hormone production; accessory organs of vas deferens, seminal vesicles, prostate gland, and bulbourethral glands; scrotum; and penis.
31.2 Describe the causes, signs and symptoms, and treatment of various disorders of the male reproductive system.	The diseases of the male reproductive system vary widely from simple inflammation to cancers, with varied signs, symptoms, and treatments. Some of these include benign prostatic hypertrophy, epididymitis, impotence (also called erectile dysfunction, or ED), prostate cancer, prostatitis, and testicular cancer.
31.3 Summarize the organs of the female reproductive system, including the locations, structures, and functions of each.	The organs of the female reproductive system include the ovaries, fallopian tubes, uterus, and vagina. The accessory organs and structures include the mons pubis, labia majora and labia minora, clitoris, urethral meatus, vaginal orifice, Bartholin's glands, perineum, and mammary glands.
31.4 Describe the causes, signs and symptoms, and treatment of various disorders of the female reproductive system.	The diseases of the female reproductive system vary widely from simple inflammation to cancers, with varied signs, symptoms, and treatments. Some of these include breast cancer, cervical cancer, cervicitis, dysmenorrhea, endometriosis, fibrocystic breast disease, ovarian cancer, premenstrual syndrome (PMS), uterine (endometrial) cancer, vaginitis, and vulvovaginitis.
31.5 Explain the process of pregnancy, including fertilization, the prenatal period, and fetal circulation.	Fertilization occurs with the union of a sperm cell and an ovum, usually within the fallopian tubes, but it may occur anywhere in the female reproductive tract. The fertilized ovum, now a blastocyst, implants in the endometrial wall of the uterus. The embryonic period occurs from week 2 through week 8 of the pregnancy; the fetal period is from week 9 through delivery.
31.6 Describe the birth process, including the postnatal period.	The birth process ends pregnancy and occurs in three stages: dilation (effacement), in which the cervix thins and softens and dilates up to 10 cm; expulsion (parturition), in which the baby is expelled from the vagina; and placental stage (afterbirth), in which the placenta is expelled through the vagina. The postnatal period is the 6-week period following birth, when the baby's organs continue to mature and the baby adjusts to life outside the uterus.

LEARNING OUTCOMES

31.7 Compare several birth control methods and their effectiveness.	Some of the contraceptive methods include coitus interruptus; the rhythm method; mechanical barriers; chemical barriers; oral contraceptives; injectable, implantable, and insertable contraceptives; transdermal contraceptives; and surgical methods.
31.8 Explain the causes of and treatments for infertility.	The causes of infertility are varied, with about 15% of infertility from unknown causes. There are a number of infertility tests and treatments; the treatment plan depends on the reason for the infertility.
31.9 Describe the causes, signs and symptoms, and treatments of the most common sexually transmitted infections.	There are many sexually transmitted infections occurring in both sexes, all passed between sexual partners (both heterosexual and same-sex partners), with varied signs, symptoms, and treatments. Some of these include AIDS (acquired immunodeficiency syndrome), chlamydia, genital warts, gonorrhea, pubic lice, syphilis, and trichomoniasis.

CASE STUDY CRITICAL THINKING

© ERproductions Ltd/Blend Images LLC RF

Recall Raja Lautu from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. From Raja's symptoms, which STI might you suspect she is experiencing?

2. What causes this STI, and how is it treated?

3. Why is it important for her sexual partner to be treated?

EXAM PREPARATION QUESTIONS

- (LO 31.1) Testosterone is produced in the _____ of the testes.
 - Seminiferous tubules
 - Epididymis
 - Vas deferens
 - Interstitial cells
 - Bulbourethral gland
- (LO 31.3) The innermost layer of the uterus is the
 - Endometrium
 - Myometrium
 - Perimetrium
 - Infundibulum
 - Cervical orifice
- (LO 31.4) In _____, the normal uterine lining is found outside of the uterus.
 - PID
 - Endometriosis
 - PMS
 - Dysmenorrhea
 - Trichomoniasis
- (LO 31.6) A newborn is described as a neonate until it reaches the age of
 - 4 weeks
 - 2 months
 - 6 weeks
 - 6 months
 - 1 year

5. (LO 31.7) “The patch” is a _____ method of contraception.
 - a. Barrier
 - b. Mechanical
 - c. Transdermal
 - d. Chemical
 - e. Surgical
6. (LO 31.2) An enlargement of the prostate gland due to normal hormonal changes as a man ages is known as
 - a. Epididymitis
 - b. Erectile dysfunction
 - c. Prostatitis
 - d. Testicular cancer
 - e. Benign prostatic hypertrophy
7. (LO 31.3) The union of the nucleus of an ovum and a the nucleus of a sperm to create one nucleus containing 46 chromosomes results in a(n)
 - a. Blastocyst
 - b. Embryo
 - c. Zygote
 - d. Inner cell mass
 - e. Morula
8. (LO 31.8) Which of the following is *not* a test performed to diagnose infertility?
 - a. Semen analysis
 - b. Endometrial biopsy
 - c. Hysterosalpingogram
 - d. Amniocentesis
 - e. Blood hormone measurement
9. (LO 31.9) The most commonly reported STI in the United States is
 - a. Gonorrhea
 - b. Chlamydia
 - c. Syphilis
 - d. AIDS
 - e. Trichomoniasis
10. (LO 31.5) The structure in a fetus that allows most of the blood to bypass the liver is the
 - a. Ductus venosus
 - b. Foramen ovale
 - c. Ductus arteriosus
 - d. Fossa ovalis
 - e. Ligamentum arteriosum

Go to CONNECT to see an animation exercise about *Meiosis* vs. *Mitosis*.

M E D I C A L T E R M I N O L O G Y P R A C T I C E

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **spermato/cyte** = spermato means “sperm” + cyte means “cell”
SPERMATOCYTE means “sperm cell.”

- | | | |
|----------------|-----------------|------------------|
| 1. blastocyst | 5. hysterectomy | 9. oviduct |
| 2. ectoderm | 6. lactiferous | 10. vasectomy |
| 3. endometrium | 7. neonate | 11. vaginosis |
| 4. episiotomy | 8. oogenesis | 12. oophorectomy |

The Digestive System

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Sylvia Gonzales	9/1/19XX	Penicillin
PATIENT INFORMATION	Attending	MRN	Other Information
	Alexis N. Whalen, MD	341-73-792	NIDDM blood sugars erratic

Yesterday afternoon, Sylvia Gonzales, a 51-year-old female, came to the gastroenterologist's office complaining of severe pain in her upper right abdomen. She was nauseated and stated that for several months—and especially following

© McGraw-Hill Education

meals—she had been having periodic abdominal pain. After several tests, she was diagnosed as having gallstones and was scheduled for the surgical removal of her gallbladder.

Keep Sylvia in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 32, you will be able to:

- 32.1** Describe the organs of the alimentary canal and their functions.
- 32.2** Explain the functions of the digestive system's accessory organs.
- 32.3** Identify the nutrients absorbed by the digestive system and where they are absorbed.
- 32.4** Describe the causes, signs and symptoms, and treatments of various common diseases and disorders of the digestive system.

KEY TERMS

alimentary canal	feces
bile	glycogen
bolus	lipid
cardiac sphincter	mechanical digestion
chemical digestion	nutrient
cholesterol	palate
chyme	peritoneum
diverticula	triglycerides
esophageal hiatus	uvula

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.8** Identify common pathology related to each body system including:
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structures and functions
- b. Describe common diseases, symptoms and etiologies as they apply to each body system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- a. Define and use entire basic structure of medical words and be able to accurately identify in the correct context, i.e. root, prefix, suffix, combinations, spelling, and definitions
- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

► Introduction

Digestion is the mechanical and chemical breakdown of foods into forms that your body cells can absorb. The digestive system's organs carry out the digestive process and can be divided into two categories: organs of the alimentary (digestive) canal and accessory organs. Organs of the **alimentary canal** form a tube or pathway that extends from the mouth to the anus. These organs include the mouth, pharynx, esophagus, stomach, small intestine, large intestine, and anal canal. The accessory organs include the teeth, tongue, salivary glands, liver, gallbladder, and pancreas (Figure 32-1). You may find it helpful to review the *Organization of the Body* chapter to revisit the abdominal regions and quadrants while studying the organs described in this chapter.

► Characteristics of the Alimentary Canal

LO 32.1

The wall of the alimentary canal consists of four layers:

- **Mucosa.** The mucosa is the innermost layer of the canal wall. It is made mostly of epithelial tissue that secretes enzymes and mucus into the lumen, or passageway, of the canal. This layer also is active in absorbing nutrients.
- **Submucosa.** The submucosa is the layer just outside the mucosa. It contains loose connective tissue, blood vessels, glands, and nerves. The blood vessels in this layer carry absorbed nutrients throughout the body.
- **Muscular layer.** This layer lies between the submucosa and the canal's outermost layer. It is made of layers of smooth muscle tissue and contracts to move materials through the canal.

- **Serosa.** The serosa is the double-walled, outermost layer of the canal and is also known as the **peritoneum**. The innermost wall of the serosa is known as the *visceral peritoneum*. It secretes serous fluid to keep the outside of the canal moist, preventing it from sticking to other organs or to its outer layer, the *parietal peritoneum*, also called the abdominal lining.

Smooth muscle in the canal's wall can contract to produce two basic types of movements: churning and peristalsis. Churning mixes substances in the canal. Peristalsis propels substances through the tract (Figure 32-2).

The Mouth

The mouth, also known as the *buccal cavity*, takes in food and reduces its size through chewing—a process known as **mechanical digestion**. The mouth also starts the process of **chemical digestion** of food because saliva (spit) contains the enzyme amylase, which breaks down carbohydrates.

The cheeks consist of skin, adipose tissue, skeletal muscles, and an inner lining of moist, stratified squamous epithelium. The cheeks hold food in the mouth. The lips contain sensory nerve fibers that can judge the temperature of food before it enters the mouth. The tongue is made mostly of skeletal muscles and is covered by a mucous membrane. The body of the tongue is held to the floor of the oral cavity by a flap of mucous membrane called the *lingual frenulum*. The tongue mixes food in the mouth and holds it between the teeth. It also contains taste buds. The back of the tongue contains two lumps of lymphoid tissue called *lingual tonsils*, which destroy bacteria and viruses on the back of the tongue.

The **palate** is the roof of the mouth. It separates the oral cavity from the nasal cavity. The front of the palate—the hard

FIGURE 32-1 Major organs of the digestive system.

FIGURE 32-2 Movements through the alimentary canal: (a) Churning movements move substances back and forth to mix them. (b) Peristalsis moves contents along the canal.

palate—is rigid because it has bony plates in it. The back of the palate, or soft palate, lacks bony material, so it is not rigid. The back of the soft palate hangs down into the throat. This portion of the soft palate is called the **uvula**. It prevents food and liquids from entering the nose during swallowing (Figure 32-3).

At the back of the mouth, where the oral cavity joins the pharynx in the area known as the *oropharynx*, are two masses of lymphoid tissue called *palatine tonsils*. Just above the

palatine tonsils, in the area known as the *nasopharynx* (the nasal cavity joins the pharynx here), are two more masses of lymphoid tissue called the *pharyngeal tonsils*, or *adenoids*. These masses of lymphoid tissue protect the area from bacteria and viruses.

Humans have 32 teeth—16 on the upper jaw and 16 on the lower jaw—which through mastication (chewing) work to decrease the size of food particles. Different types of teeth are adapted to handle food in different ways. The most

FIGURE 32-3 Structures of the mouth.

FIGURE 32-4 Structure of a cuspid tooth.

medial teeth, called *incisors*, act as chisels to bite off food pieces. Teeth called *cuspid*s, also known as the canines, are the sharpest teeth and designed to tear tough food (Figure 32-4). The back teeth, called *bicuspid*s and *molars*, are flat and designed to grind food (Figure 32-5).

Salivary glands secrete saliva—a mixture of water, enzymes, and mucus—and are made of two types of cells: serous cells and mucous cells. Serous cells secrete a fluid made mostly of water, and they secrete amylase. Mucous cells secrete mucus. The mass created by food mixed with the saliva and mucous mixture is called a **bolus**.

All major salivary glands are paired (Figure 32-6):

- *Parotid glands* are the largest of the salivary glands, located beneath the skin just in front of the ears.
- *Submandibular glands* are located in the floor of the mouth just inside the surface of the mandibles (jaws).
- *Sublingual glands* are the smallest of the salivary glands, located in the floor of the mouth beneath the tongue.

The Pharynx

The pharynx, commonly called the throat, is a long, muscular structure that extends from the area behind the nose to the esophagus. It connects the nasal cavity with the oral cavity for breathing through the nose. It also pushes food into the esophagus (Figure 32-7).

The divisions of the pharynx are the:

- *Nasopharynx*: the portion behind the nasal cavity.

FIGURE 32-5 Types of teeth.

- *Oropharynx*: the portion behind the oral cavity.
- *Laryngopharynx*: the portion behind the larynx. The laryngopharynx continues as the esophagus.

FIGURE 32-6 Major salivary glands.

Swallowing is largely a reflex. In other words, it is an automatic response that does not require much thought. The following events occur during swallowing:

1. The soft palate rises, causing the uvula to cover the opening between the nasal cavity and the oral cavity.
2. The epiglottis covers the opening of the larynx so that food does not enter it (see Figure 32-7).
3. The tongue presses against the roof of the mouth, forcing food into the oropharynx.
4. The muscles in the pharynx contract, forcing food toward the esophagus.
5. The esophagus opens.
6. The muscles of the pharynx push food into the cardiac sphincter.

The Esophagus

The esophagus is a muscular tube that connects the pharynx to the stomach (Figures 32-7 and 32-8). It descends through the thoracic cavity, through the diaphragm, and into the abdominal cavity, where it joins the stomach. The hole in the diaphragm that the esophagus goes through is called the **esophageal hiatus**. This hiatus is a place where hernias commonly occur.

FIGURE 32-7 Sagittal section of the mouth, nasal cavity, and pharynx.

FIGURE 32-8 Regions of the stomach.

A hernia develops when an organ pushes through a wall that contains it. A hiatal hernia occurs when the stomach gets pushed up into the thoracic cavity through the esophageal hiatus.

The **cardiac sphincter**, also known as the *lower esophageal sphincter*, controls the movement of food into the stomach. As stated in earlier chapters, sphincters are circular bands of muscle located at the openings of many tubes in the body. They open and close to allow or prevent the movement of substances out of a tube.

The Stomach

The stomach lies below the diaphragm in the left upper quadrant of the abdominal cavity. The folds of the inner lining of the stomach are called *rugae*. The stomach receives the food bolus from the esophagus, mixes food with gastric juice (secretions of the stomach lining), starts protein digestion, and moves food into the small intestine. The mixture of food and gastric juices is called **chyme**. Once chyme is well mixed, stomach contractions push it into the small intestine a little at a time. It takes 4 to 8 hours for the stomach to empty following a meal. The stomach does not absorb many substances, but it can absorb alcohol, water, and some fat-soluble drugs.

The beginning portion of the stomach that is attached to the esophagus is called the *cardiac region*. The portion of the stomach that balloons over the cardiac region is the *fundus*. The main part of the stomach is called the *body*, and the narrow portion connected to the small intestine is the *pylorus*. The *pyloric sphincter* controls the movement of substances from the pylorus of the stomach into the small intestine (Figure 32-8).

The lining of the stomach contains gastric glands, which are made of the following cell types:

- **Mucous cells:** secrete mucus to protect the lining of the stomach
- **Chief cells:** secrete pepsinogen, which becomes *pepsin* in the presence of acid; pepsin digests proteins
- **Parietal cells:** secrete hydrochloric acid, which is necessary to convert pepsinogen to pepsin; they also secrete *intrinsic factor*, which is necessary for vitamin B₁₂ absorption

When a person smells, tastes, or sees appetizing food, the parasympathetic nervous system stimulates the gastric glands to secrete their products. A hormone called *gastrin*, made by the stomach, also stimulates the gastric glands to become active. A hormone called *cholecystokinin (CCK)*, made by the small intestine, inhibits gastric glands.

If a patient is unable to swallow for any reason, a gastrostomy tube, or G tube, may be inserted into the patient's stomach so that he can be fed liquid meals, like Ensure®, through this tube.

The Small Intestine

The small intestine is a coiled, tubular organ that extends from the stomach to the large intestine (Figure 32-9). It fills most of the abdominal cavity. The small intestine carries out most of the actual digestion in the body and is responsible for absorbing most of the nutrients into the bloodstream.

The beginning of the small intestine is called the *duodenum*. It is C-shaped and relatively short. The middle portion of the small intestine is called the *jejunum*. It is coiled and forms the majority of the small intestine. If a patient's stomach is diseased or removed, a jejunostomy, or J, tube may be inserted into the jejunum to allow her to receive nutrition.

The last portion of the small intestine is called the *ileum*, and it is directly attached to the large intestine. The jejunum and ileum are held in the abdominal cavity by a fan-like tissue called the *mesentery*, which attaches to the posterior wall of the abdomen.

The lining of the small intestine contains cells that have *microvilli*. Microvilli greatly increase the surface area of the small intestine so that it can absorb nutrients more efficiently. The lining of the small intestine also contains glands that secrete various substances, including mucus and water. Water aids in digestion, but infections or exposure to some toxins cause the secretion of too much water, and this leads

FIGURE 32-9 Parts of the small intestine.

to diarrhea—which in turn aids the body in eliminating the toxins. It also means, however, that needed nutrients are not absorbed in the small intestine as usual. The mucus secreted by the small intestine helps protect its lining. The parasympathetic nervous system and the stretching of the wall of the small intestine as it fills are the primary factors that trigger the small intestine to secrete its products. The following are the major enzymes the small intestine secretes:

- *Peptidases*. These enzymes digest proteins.
- *Sucrase, maltase, and lactase*. These enzymes digest sugars. A person who cannot produce lactase will not be able to digest lactose, which is the sugar in dairy products. This causes a condition called *lactose intolerance*.
- *Intestinal lipase*. This enzyme digests fats.

The small intestine absorbs almost all nutrients (water, glucose, amino acids, fatty acids, glycerol, and electrolytes) as the wall of the small intestine contracts to mix chyme and to propel it toward the large intestine. The *ileocecal sphincter* controls the movement of chyme from the ileum to the *cecum*, which is the beginning of the large intestine.

The Large Intestine

The large intestine begins at the ileum of the small intestine and ends where it opens to the outside of the body as the anus. The beginning of the large intestine is called the cecum. Projecting off the cecum is the *vermiform appendix*, which is made mostly of lymphoid tissue. It was once thought to have no function, but it is now thought to have a role in immunity. The cecum eventually gives rise to the ascending colon, which is the portion of the large intestine that runs up the right side of the abdominal cavity. If you remember that the appendix is in the right lower quadrant (RLQ), it will be easy to remember that the ascending colon also goes up the right side of the abdomen. The ascending colon becomes the transverse colon as it crosses the abdominal cavity; from there, it becomes the descending colon as it descends the left side of the abdominal cavity. In the pelvic cavity, the descending colon then forms the S-shaped tube called the *sigmoid colon*.

The Rectum and Anal Canal

Eventually, the sigmoid colon straightens out to become the *rectum*. The last few centimeters of the rectum are known as the *anal canal*, and the opening of the anal canal to the outside of the body is called the *anus* (Figure 32-10).

FIGURE 32-10 Parts of the large intestine.

The lining of the large intestine secretes mucus to aid in the movement of substances. As chyme leaves the small intestine and enters the large intestine, the proximal portion of the large intestine absorbs water and a few electrolytes from it. The leftover chyme is then called **feces**, which are made of undigested solid materials, a little water, ions, mucus, cells of the intestinal lining, and bacteria.

The contractions of the large intestine propel feces forward, but these contractions normally occur periodically and as mass movements. Mass movements trigger the *defecation reflex*, which allows the anal sphincters to relax and feces to move through the anus in the process of elimination. The squeezing actions of the abdominal wall muscles also aid in emptying the large intestine.

► Characteristics of the Digestive Accessory Organs

LO 32.2

Although they do not form part of the alimentary canal, the digestive system's accessory organs play important roles in digestion. They deliver enzymes and other substances to the alimentary canal to assist with the digestive process.

The Liver

The liver is a large organ that fills most of the upper-right abdominal quadrant. It is reddish-brown in color and enclosed by a tough capsule that divides the liver into a large right lobe and a small left lobe (Figure 32-11). Each lobe is separated into smaller divisions called *hepatic lobules*. Branches of the *hepatic portal vein* carry blood from the digestive organs to the hepatic lobules. These hepatic lobules contain macrophages that destroy bacteria and viruses in the blood. Most people associate the liver with cleansing and detoxifying the blood, but it also has other functions important to the digestive system. Each lobule contains many cells called *hepatocytes*. Hepatocytes process the nutrients in blood and make **bile**, which is used in the digestion of fats. Bile leaves the liver through the

hepatic duct. The *hepatic duct* merges with the *cystic duct* (the duct from the gallbladder) to form the *common bile duct*. This duct delivers bile to the duodenum. Another important function of the liver is to store vitamins and iron.

The Gallbladder

The gallbladder is a small, sac-like structure located beneath the liver (Figures 32-11 and 32-12). Its only function is to store bile, which leaves the gallbladder through the cystic duct. The hormone cholecystikinin causes the gallbladder to release bile. The salts in bile break large fat globules into smaller ones so that the digestive enzymes can more quickly digest them. Bile salts also increase the absorption of fatty acids, cholesterol, and fat-soluble vitamins into the bloodstream.

The Pancreas

The pancreas is located behind the stomach. Pancreatic *acinar cells* produce pancreatic juices, which ultimately flow through the pancreatic duct to the duodenum (Figure 32-12). Pancreatic juices contain the following enzymes:

- *Pancreatic amylase*, which digests carbohydrates
- *Pancreatic lipase*, which digests lipids
- *Nucleases*, which digest nucleic acids
- *Trypsin*, *chymotrypsin*, and *carboxypeptidase*, which digest proteins

The pancreas also secretes bicarbonate ions into the duodenum that neutralize the acidic chyme arriving from the stomach. The parasympathetic nervous system stimulates the pancreas to release its enzymes. The hormones secretin and cholecystikinin also stimulate the pancreas to release digestive enzymes. Secretin and cholecystikinin come from the small intestine.

FIGURE 32-11 The liver is located in the right upper quadrant of the abdomen. (a) Anterior and (b) posteroinferior views show the four lobes of the liver, gallbladder, inferior vena cava, hepatic portal vein, and hepatic artery.

FIGURE 32-12 Pancreas and its connections to the gallbladder and duodenum.

► The Absorption of Nutrients LO 32.3

Necessary food substances are known as **nutrients**. They include carbohydrates, proteins, lipids, vitamins, minerals, and water.

Three types of carbohydrates that humans ingest are starches (polysaccharides), simple sugars (monosaccharides and disaccharides), and cellulose. Starches come from foods such as pasta, potatoes, rice, and breads.

Monosaccharides and disaccharides are obtained from sweet foods and fruits. Most body cells use the monosaccharide glucose to make adenosine triphosphate (ATP). ATP provides a type of chemical energy needed by the body. When a person has an excess of glucose, it can be stored in the liver and skeletal muscle cells as **glycogen**.

Cellulose is a type of carbohydrate that humans cannot digest; it is found in many vegetables. It is necessary for digestion because it provides fiber or bulk for the large intestine, which helps the large intestine to empty more regularly. According to Harvard Medical International, a connection

has been made between higher-fiber diets and a decrease in colon diseases, including cancer. This may be because fiber increases water absorption and bulk, causing more rapid emptying of the colon and decreasing the production of benign growths, such as adenomas or polyps, which increase the risk of cancer. Fiber may also neutralize toxins produced by gastrointestinal (GI) tract bacteria.

Lipids (fats) are obtained through various foods. The most abundant dietary lipids are **triglycerides**. They are found in meats, eggs, milk, and butter. **Cholesterol** is another common dietary lipid and is found in eggs, whole milk, butter, and cheeses. Lipids are used by the body primarily to make energy when glucose levels are low. Excess triglycerides are stored in adipose tissue. Cholesterol is essential to cell growth and function; cells use it to make cell membranes and some hormones. People should have the essential fatty acid linoleic acid in their diet because the body cannot make it. This fatty acid is found in corn and sunflower oils. People also need a certain amount of fat to absorb fat-soluble vitamins.

CAUTION: HANDLE WITH CARE

Aging and the Digestive System

As a person gets older, natural effects of aging cause changes in the digestive system, which can have important effects on both nutrition and medication dosages. As a medical assistant, you should be aware of these changes and their consequences for elderly patients.

In general, as a person ages, the mucus lining thins and the blood supply and number of smooth muscle cells within the alimentary canal decrease, which lead to decreased motility. The decreasing motility often causes gastroesophageal reflux disease (GERD) and constipation. The decreasing blood supply also affects the patient’s ability to absorb medications and nutrients. Gastric secretions from the stomach, liver, and pancreas decrease, and the liver’s ability to detoxify the blood also lessens. This makes adjusting medication dosages more difficult until it is clear (through lab tests or patient response) how rapidly and how much medication the patient’s body is absorbing.

If the patient drinks alcohol, he may notice a difference in the way alcohol affects him. Advancing age also leaves the patient more likely to develop ulcerations and cancers of the GI system, including colorectal cancer, which is the second-leading cause of cancer deaths in the United States, according to the American Cancer Society.

Many elderly people state that their sense of taste is altered and that food loses some of its enjoyment. If the patient is lonely or feels isolated as a result of her social situation, and/or if depression is a component, her diet will likely change because “it is no fun or too much work to cook just for myself.”

The medical assistant should be aware of these possibilities, looking for clues like weight loss, depression, or patient comments, and should relate information to the healthcare provider with a goal of securing social service assistance for the patient if needed.

The fat-soluble vitamins are vitamins A, D, E, and K; the water-soluble vitamins are all the B vitamins and vitamin C. The many functions of vitamins are summarized in Table 32-1.

Minerals—primarily found in bones and teeth—make up about 4% of total body weight. Cells use minerals to make enzymes, cell membranes, and various proteins like hemoglobin. The most important minerals to the human body are calcium, phosphorus, sulfur, sodium, chlorine, and magnesium. The body needs trace elements, including iron, manganese, copper, iodine, and zinc, in very small amounts.

Foods rich in protein include meats, eggs, milk, cheese, fish, chicken, turkey, nuts, seeds, and beans. Protein requirements vary from individual to individual, but all people must take in proteins that contain certain amino acids (called *essential amino acids*) because the body cannot make them. The body uses proteins for growth and tissue repair.

Keep in mind that an individual’s ability to absorb nutrients changes over the course of his or her lifetime. See the feature *Caution: Handle with Care* for more information.

TABLE 32-1 Common Vitamins and Their Importance in the Body	
Vitamin	Function
Vitamin A	Needed for the production of visual receptors, mucus, the normal growth of bones and teeth, and the repair of epithelial tissues
Vitamin B ₁ (thiamine)	Needed for carbohydrate metabolism
Vitamin B ₂ (riboflavin)	Needed for carbohydrate and fat metabolism and for the growth of cells
Vitamin B ₆	Needed for protein, antibody, and nucleic acid synthesis
Vitamin B ₁₂ (cyanocobalamin)	Needed for myelin production and carbohydrate and nucleic acid metabolism
Biotin	Needed for protein, fat, and nucleic acid metabolism
Folic acid	Needed for the production of amino acids, DNA, and red blood cells
Pantothenic acid	Needed for carbohydrate and fat metabolism
Niacin	Needed for carbohydrate, protein, fat, and nucleic acid metabolism
Vitamin C (ascorbic acid)	Needed for the production of collagen, amino acids, and hormones and for iron absorption
Vitamin D	Needed for calcium absorption
Vitamin E	Antioxidant that prevents the breakdown of certain tissues
Vitamin K	Needed for blood clotting

Common Diseases and Disorders of the Digestive System

APPENDICITIS is an inflammation of the appendix. If not treated promptly, it can be life-threatening.

Causes. This disorder may be caused by an appendix blocked by feces or tumor, infection, or other *idiopathic* (unknown) cause.

Signs and Symptoms. The signs and symptoms include lack of appetite, pain in the RLQ that may radiate throughout the abdomen and even down the right leg, nausea, slight fever, and an increased white blood cell (WBC) count.

Treatment. The primary treatments are antibiotics to prevent infection and an *appendectomy* to remove the appendix.

CIRRHOSIS is a chronic liver disease in which normal liver tissue is replaced with nonfunctional scar tissue.

Causes. This disease is often an autoimmune disease. It may also be caused by some medications and alcohol consumption. Hepatitis B and C infections can also contribute to the development of cirrhosis.

Signs and Symptoms. This disease has many symptoms, including anemia, fatigue, mental confusion, fever, vomiting, blood in the vomit, an enlarged liver, jaundice, unintended weight loss, swelling of the legs or abdomen, abdominal pain, decreased urine output, and pale feces.

Treatment. Alcohol consumption should be discontinued. A patient with cirrhosis may be given various medications, including antibiotics and diuretics. A liver transplant may be needed for the most seriously ill patients.

CHOLELITHIASIS, or gallstones, are hard deposits that usually consist of either cholesterol or bilirubin. They are more common in women than in men.

Causes. Gallstones can be caused by a variety of factors, including diabetes, cirrhosis, and other medical conditions; rapid weight loss; failure of the gallbladder to empty completely, which may occur during pregnancy; and organ transplant.

Signs and Symptoms. Some people who have gallstones do not have symptoms. If symptoms do occur, they may include pain in the right upper quadrant (RUQ) of the abdomen, fever, jaundice, nausea and vomiting, and clay-colored feces.

Treatment. Surgery to remove the stones is the most common treatment for people who have symptoms associated with gallstones. The most commonly used procedure is *laparoscopic cholecystectomy*. Another procedure, *lithotripsy*, is also a treatment

option. It uses electrohydraulic shock waves to dissolve or break up the stones without the need for surgery. Medications are also used in some cases, but they take a long time to work.

COLITIS is inflammation of the large intestine. This condition can be chronic or short lived, depending on the cause.

Causes. Colitis can be caused by a viral or bacterial infection or the use of antibiotics. Ulcers in the large intestine, Crohn's disease, various other diseases, and stress may also contribute to the development of this disorder.

Signs and Symptoms. The primary symptoms are abdominal pain, bloating, and diarrhea.

Treatment. The first goal of therapy is to treat the underlying causes. Changing antibiotics, treating existing ulcers, and drinking plenty of fluids are treatment options. In advanced cases, surgery to remove the affected area of the colon, known as a *colectomy*, may be recommended. If too much of the colon is affected, a *colostomy* may be performed. In this procedure, the majority of the colon is removed and the opening to the outside of the body is moved to the abdomen, where an appliance known as an ostomy, usually with a collecting device commonly called a bag, collects fecal material.

COLORECTAL CANCER usually comes from the lining of the rectum or colon. This type of cancer is curable if treated early.

Causes. The causes are mostly unknown, although research is putting some blame on high-fat/low-fiber diets. Polyps in the colon or rectum can become cancerous, leading to this disease. Colorectal cancer may be prevented through regular screenings for polyps, which is done with a procedure known as a colonoscopy.

Signs and Symptoms. Anemia, unintended weight loss, abdominal pain, blood in the feces, narrow feces, or changes in bowel habits are all common symptoms.

Treatment. Chemotherapy is the first line of treatment. Surgery to remove a cancerous tumor or the affected portions of the colon or rectum (colectomy or colostomy) may be needed in more advanced cases.

CONSTIPATION is the condition of difficult defecation, which is the elimination of feces.

Causes. The primary causes are lack of physical activity, lack of fiber and adequate water in the diet, the use of certain medications, and thyroid and colon disorders.

Signs and Symptoms. Common signs and symptoms include infrequent bowel movements (for example, no bowel movement for 3 days), bloating, abdominal pain and pain during bowel movements, hard feces, and blood on the surface of feces.

Treatment. Treatment includes an increase in dietary fiber; adequate fluid intake; regular exercise; and the use of stool softeners, laxatives, and enemas (for extreme cases only).

CROHN'S DISEASE is a common disorder called *inflammatory bowel disease*. It typically affects the end of the small intestine.

Causes. This is an autoimmune disorder.

Signs and Symptoms. The signs and symptoms of Crohn's disease include fever, tender gums, joint pain, GI ulcers, abdominal pain and gas, constipation or diarrhea, abnormal abdominal sounds, weight loss, intestinal bleeding, and blood in the feces.

Treatment. The first treatment is to change the patient's diet. Other treatments include medications to reduce inflammation, including steroids, as well as antibiotics and bowel "rest" in which IV (intravenous) feedings are given so that the patient's digestive system is not used. For the most serious cases, surgery to remove the affected part of the intestine may be needed. This procedure is known as an *enterectomy*.

DIARRHEA is the condition of watery and frequent feces. Many cases of diarrhea do not require treatment because they usually stop within a day or two.

Causes. The causes of diarrhea include bacterial, viral, or parasitic infections of the digestive system. It may also be caused by the ingestion of toxins; food allergies, including lactose intolerance; ulcers; Crohn's disease; laxative use; antibiotics; chemotherapy; and radiation therapy. Diarrhea related to infections may be prevented by washing hands thoroughly and cooking food properly.

Signs and Symptoms. The symptoms include abdominal cramps, watery feces, and the frequent passage of feces.

Treatment. Patients should drink fluids to prevent dehydration. The underlying causes, if known, should be treated. Medications and dietary changes are the primary treatment options. In severe cases, antidiarrheal medications such as Lomotil® may be prescribed.

DIVERTICULITIS is inflammation of diverticula in the intestine. **Diverticula** are abnormal dilations or pouches in the intestinal wall. When the diverticula are not inflamed, the condition is known as **DIVERTICULOSIS**.

Causes. The causes are mostly unknown. Lack of fiber in the diet and a bacterial infection of the diverticula can cause this disorder. Patients may find that certain foods, like peanuts and seeds, aggravate this disorder.

Signs and Symptoms. Signs and symptoms include fever, nausea, abdominal pain, constipation or diarrhea, blood in the feces, and a high WBC.

Treatment. Treatments include a high-fiber diet, antibiotics, and keeping a food diary to track foods that cause flare-ups. A *colectomy* (surgery to remove the affected portion of the intestine) may be necessary in severe cases.

GASTRITIS is an inflammation of the stomach lining. It is often referred to as an "upset stomach."

Causes. Gastritis can be caused by bacteria or viruses, some medications, alcohol use, spicy foods, excessive eating, poisons, and stress. Cooking food properly to kill harmful bacteria and viruses can help to prevent this condition.

Signs and Symptoms. Symptoms include nausea, lack of appetite, heartburn, vomiting, and abdominal cramps. An upper

endoscopy may be done to confirm the diagnosis and rule out more serious conditions, such as an ulcer or cancer.

Treatment. Lifestyle changes should be implemented to avoid foods or medications that irritate the stomach lining. Treatment with various medications to reduce the production of stomach acids, such as Pepcid® and Nexium®, can provide relief from the symptoms of this disorder.

GASTROESOPHAGEAL REFLUX DISEASE (GERD) is more commonly known as heartburn. It occurs when stomach acids are pushed into the esophagus.

Causes. Alcohol, some foods, a defective cardiac sphincter, pregnancy, obesity, a hiatal hernia, and repeated vomiting can contribute to the development of this disease.

Signs and Symptoms. Common symptoms include frequent burping, difficulty swallowing, a sore throat, a burning sensation in the chest following meals and nausea when lying down, and blood in the vomit.

Treatment. Treatment includes weight loss, making dietary changes, reducing alcohol consumption, taking medications such as Pepcid® and Nexium®, and elevating the head, neck, and chest when lying down.

HEMORRHOIDS are varicose veins of the rectum or anus.

Causes. Hemorrhoids are caused by constipation, excessive straining during bowel movements, liver disease, pregnancy, and obesity.

Signs and Symptoms. Signs and symptoms include itching in the anal area, painful bowel movements, bright red blood on feces, and veins that protrude from the anus.

Treatment. Constipation can be avoided or lessened by eating a high-fiber diet. Other treatments include stool softeners, medications to reduce hemorrhoid inflammation, and the surgical removal of hemorrhoids (*hemorrhoidectomy*).

HEPATITIS is inflammation of the liver. There are many different types of hepatitis.

Causes. Causes include bacteria, viruses, parasites, immune disorders, alcohol and drug use, and an overdose of acetaminophen. Preventive measures include getting hepatitis B (HBV) vaccinations, practicing safer sex, avoiding undercooked food (especially seafood), and using prescription or over-the-counter drugs (especially those containing acetaminophen) at their recommended dosages or as prescribed by a physician.

Signs and Symptoms. Symptoms include mild fever, bloating, lack of appetite, nausea, vomiting, abdominal pain, weakness, jaundice, itching in various body parts, an enlarged liver, dark urine, and breast development in males.

Treatment. Patients should avoid using alcohol and drugs as the inflamed liver cannot detoxify them. Various medications may be prescribed.

A **HIATAL HERNIA** occurs when a portion of the stomach protrudes into the chest cavity through an opening in the diaphragm.

Causes. The causes are mostly unknown, although obesity and smoking are considered risk factors. Eating small meals can be an effective preventive measure.

Signs and Symptoms. Signs and symptoms include excessive burping, difficulty swallowing, chest pain, and heartburn.

Treatment. Treatments are weight reduction, medications to reduce stomach acid production, and surgical repair of the hernia.

INGUINAL HERNIAS occur when a portion of the large intestine protrudes into the inguinal canal (groin), which is located where the thigh and the body trunk meet. In males, the hernia can also protrude into the scrotum.

Causes. The causes are mostly unknown, although these hernias may be caused by weak muscles in the abdominal walls.

Signs and Symptoms. A lump in the groin or scrotum and pain in the groin that gets worse when bending or straining are the common symptoms.

Treatment. Pain medications may be prescribed. Surgery to repair the hernia is needed, in which the large intestine is pushed back into the abdominal cavity.

ORAL CANCER usually involves the lips or tongue but can occur anywhere in the mouth. This type of cancer tends to spread rapidly to other organs.

Causes. The causes are mostly unknown, although the use of tobacco products and alcohol are known risk factors. Poor oral hygiene and ulcers in the mouth can also cause oral cancer.

Signs and Symptoms. Signs and symptoms include difficulty tasting; problems swallowing; and ulcers on the tongue, lip, or other mouth structures. Leukoplakia, or hardened white patches in the mucous membrane of the mouth, is considered a precancerous lesion. A healthcare professional should examine any abnormal patch and biopsy it if it looks suspicious.

Treatment. Radiation therapy, chemotherapy, and surgical removal of the malignant area are the treatment options.

PANCREATIC CANCER is the fourth leading cause of cancer deaths in the United States.

Causes. The causes are mostly unknown, although smoking and alcohol consumption are considered risk factors.

Signs and Symptoms. Common signs and symptoms include depression, fatigue, lack of appetite, nausea or vomiting, abdominal pain, constipation or diarrhea, jaundice, and unintended weight loss.

Treatment. Treatment includes radiation therapy, chemotherapy, and surgical removal of the tumor.

STOMACH CANCER most commonly occurs in the uppermost, or cardiac, portion of the stomach. It appears to occur more frequently in Japan, Chile, and Iceland than in the United States.

Causes. The causes are mostly unknown, although stomach ulcers may contribute to the development of stomach cancer.

Signs and Symptoms. Signs and symptoms include frequent bloating, lack of appetite, feeling full after eating small amounts, nausea, vomiting (with or without blood), abdominal cramps, excessive gas, and blood in the feces.

Treatment. Treatment includes radiation therapy, chemotherapy, and surgical removal of the tumor.

STOMACH ULCERS occur when the lining of the stomach breaks down.

Causes. Bacteria (particularly *Helicobacter pylori*), smoking, alcohol, excessive aspirin use, and hypersecretion of stomach acid can all cause stomach ulcers. They may be prevented by stopping smoking and avoiding aspirin, certain foods, and alcohol.

Signs and Symptoms. Symptoms include nausea, abdominal pain, vomiting (with or without blood), and weight loss. Diagnosis can be confirmed by an upper endoscopy.

Treatment. Treatment options include antibiotics, medications to reduce stomach acid production, *partial gastrectomy* (surgery to remove the affected portion of the stomach), and *vagotomy* (cutting the vagus nerve) to reduce the production of stomach acid.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES

32.1 Describe the organs of the alimentary canal and their functions.

KEY POINTS

The pathway of food through the alimentary canal starts with the mouth and continues through the pharynx, esophagus, stomach, small intestine, large intestine, and anal canal. The mouth takes in food and the teeth assist in reducing its size through chewing. The tongue mixes food and holds it between the teeth. The salivary glands produce saliva to moisten and break down food. The pharynx is a long, muscular tube connecting the oral and nasal cavities. It pushes food into the esophagus. The esophagus is a muscular tube that pushes food toward the stomach through muscular contractions. The stomach receives the food, mixes it with gastric juices to start protein digestion, and moves it into the small intestine. The small intestine carries out most of the nutrient absorption. The large intestine's primary job is to rid the body of solid waste by defecation.

LEARNING OUTCOMES

KEY POINTS

32.2 Explain the functions of the digestive system's accessory organs.

The accessory organs to the digestive system include the liver, gallbladder, and pancreas. As a digestive organ, the liver stores vitamins and iron and produces macrophages to fight infection. It also secretes bile for fat digestion. The gallbladder stores the bile produced by the liver. The pancreas produces pancreatic juices that assist in carbohydrate, lipid, and protein digestion.

32.3 Identify the nutrients absorbed by the digestive system and where they are absorbed.

Nutrients absorbed by the body include carbohydrates, proteins, lipids, vitamins, minerals, and water. Most of the absorption takes place in the small intestine.

32.4 Describe the causes, signs and symptoms, and treatments of various common diseases and disorders of the digestive system.

There are many common diseases and disorders of the digestive system with varied signs, symptoms, and treatments. Some of these include appendicitis, cirrhosis, cholelithiasis, colitis, colorectal cancer, constipation, Crohn's disease, diarrhea, diverticulitis, diverticulosis, gastritis, gastroesophageal reflux disease or GERD (commonly known as heartburn), hemorrhoids, hepatitis, hiatal hernia, inguinal hernia, oral cancer, pancreatic cancer, stomach cancer, and stomach ulcers.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall Sylvia Gonzales from the beginning of this chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. What is the function of the gallbladder?

2. If Sylvia does not want to have surgery, what other treatment options are available?

3. Will Sylvia need to change her diet once her gallbladder is removed?

EXAM PREPARATION QUESTIONS

1. (LO 32.1) Which layer of the digestive tract is the most active in absorbing nutrients?

- a. Mucosa
- b. Submucosa
- c. Muscular
- d. Serosa
- e. Visceral

2. (LO 32.2) Which of the following is an accessory organ of the digestive process?

- a. Stomach
- b. Small intestine
- c. Liver
- d. Esophagus
- e. Pharynx

3. (LO 32.1) Although it hangs from the soft palate, the _____ is not one of the tonsils.

- a. Lingual
- b. Uvula
- c. Palatine
- d. Pharyngeal
- e. Adenoid

4. (LO 32.1) When an organ pushes through the wall that contains it, a(n) _____ develops.

- a. Sphincter
- b. Aneurysm
- c. Ulcer
- d. Hernia
- e. Bolus

5. (LO 32.4) Also known as inflammatory bowel disease, _____ often affects the end of the small intestine.
 - a. Diverticulitis
 - b. Crohn's disease
 - c. GERD
 - d. Colitis
 - e. Cholelithiasis
6. (LO 32.2) Which of the following is made by the liver?
 - a. Amylase
 - b. Trypsin
 - c. Secretin
 - d. Bilirubin
 - e. Bile
7. (LO 32.3) Which of the following is *not* a type of carbohydrate?
 - a. Monosaccharides
 - b. Polysaccharides
 - c. Cellulose
 - d. Disaccharides
 - e. Triglycerides
8. (LO 32.3) Why do people need to include fiber in their diet?
 - a. To help the large intestine empty more regularly
 - b. To make energy when glucose levels are low
 - c. To make cell membranes and hormones
 - d. To help the body absorb fat-soluble vitamins
 - e. To help synthesize antibodies and nucleic acids
9. (LO 32.4) Which of the following terms is used to describe difficult defecation?
 - a. Cirrhosis
 - b. Constipation
 - c. Cholelithiasis
 - d. Diarrhea
 - e. Crohn's disease
10. (LO 32.4) Which disorder is commonly referred to as an "upset stomach"?
 - a. GERD
 - b. Diverticulitis
 - c. Gastritis
 - d. Hiatal hernia
 - e. Crohn's disease

M E D I C A L T E R M I N O L O G Y P R A C T I C E

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **gastr/oid** = gastr means "stomach" + oid means "resembling"
GASTROID means "resembling the stomach."

- | | | |
|---------------------|-------------------|---------------------|
| 1. bicuspid | 5. idiopathic | 9. pyloric |
| 2. carboxypeptidase | 6. laryngopharynx | 10. sublingual |
| 3. diverticulosis | 7. nuclease | 11. hematemesis |
| 4. hepatocyte | 8. polysaccharide | 12. gastroenteritis |

The Endocrine System

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Ken Washington	12/1/19XX	Sulfa
	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	891-12-743	Recent CVA w/ residual foot drop

Ken Washington, a 61-year-old man, comes to the office today complaining of feeling “odd.” His symptoms include weight loss for no apparent reason, “jitteriness” with a feeling like his heart is racing, and overall irritability. You notice that the patient’s eyes appear more prominent than normal. Ken is particularly concerned about his new symptoms, as

© McGraw-Hill Education

he was only recently discharged from the hospital after suffering a CVA. He has a residual foot drop, for which he wears a brace and is receiving physical therapy.

Keep Ken Washington in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 33, you will be able to:

- 33.1** Describe the general functions of hormones and the endocrine system.
- 33.2** Identify the hormones released by the pituitary gland, thyroid gland, parathyroid glands, adrenal glands, pancreas, and other hormone-producing organs and give the functions of each.
- 33.3** Explain the effect of stressors on the body.
- 33.4** Describe the causes, signs and symptoms, and treatments of various endocrine disorders.

KEY TERMS

- | | |
|----------------------|--------------------|
| endocrine gland | parathyroid glands |
| exocrine gland | pineal body |
| feedback loop | prostaglandins |
| gonads | steroidal hormone |
| G-protein | stressor |
| hormone | thymus |
| islets of Langerhans | thyroid gland |
| nonsteroidal hormone | |

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including:
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structures and functions
- b. Describe common diseases, symptoms and etiologies as they apply to each body system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- a. Define and use entire basic structure of medical words and be able to accurately identify in the correct context, i.e. root, prefix, suffix, combinations, spelling, and definitions
- b. Build and dissect medical terms from roots/ suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

Introduction

The endocrine (*endo-*, meaning “within,” and *-crine*, meaning “to secrete”) system includes the organs of the body that secrete hormones directly into body fluids such as blood. Hormones help to regulate the chemical reactions within cells. They therefore control the functions of the organs, tissues, and other cells. In this chapter, you will learn about the processes and organs of the endocrine system. Figure 33-1 shows the organs of the endocrine system, as well as the heart and kidney, both of which secrete a hormone, although hormone secretion is not the primary function of either of them. As shown, the gastrointestinal (GI) tract also secretes hormones, but again hormone secretion is not its primary function.

Hormones

LO 33.1

Endocrine glands are ductless glands. This means they release their hormones directly into the tissues they act upon, or into the bloodstream, which carries the hormone to the target cells. As you study each gland discussed in this chapter, refer to Figure 33-1 for its location.

Hormones are chemicals secreted by a cell that affect the functions of other cells. Once released, most hormones enter the bloodstream, which transports them to their target cells. A hormone’s target cells are those that contain the receptors for the hormone. A hormone cannot affect a cell unless the cell has receptors for it, in much the same way that a locked door needs the key specifically cut to open its lock. Table 33-1 outlines the endocrine glands, the hormone(s) secreted by each, and the action resulting from each hormone.

Types of Hormones

Many hormones in the body are derived from steroids. Steroids are soluble in lipids (fats) and can therefore cross cell membranes easily. Once a **steroidal hormone** is inside a cell, it binds to its receptor, which is commonly in the cell’s nucleus. The hormone-receptor complex turns a gene on or off. When new genes are turned on or off, the cell begins to carry out new functions, and this is ultimately how steroidal hormones affect their target cells. Examples of steroidal hormones are estrogen, progesterone, testosterone, and cortisol.

Nonsteroidal hormones are made of amino acids or proteins. Proteins cannot easily cross the cell membrane. Therefore, these hormones bind to receptors on the cell’s surface. The hormone-receptor complex in the membrane usually activates a G-protein. The **G-protein** causes enzymes inside the cell to be turned on. Different chemical reactions then begin inside the cell, and the cell takes on new functions.

Prostaglandins (tissue hormones) are local hormones. They are derived from lipid molecules and typically do not need to travel in the bloodstream to find their target cells. Instead, their target cells are located in the same area of tissue where the prostaglandin hormone is created. Prostaglandins have the same effects as other hormones and are produced by many body organs, including the kidneys, stomach, uterus, heart, and brain.

Negative and Positive Feedback Loops

Hormone levels are controlled by a mechanism known as a **feedback loop**, which can be negative or positive (see Figure 33-2). In a negative feedback loop, a stimulus such as eating raises blood sugar levels. This increase is detected by the

FIGURE 33-1 Endocrine system—endocrine glands and other organs that secrete hormones are found throughout the body. They produce various types of hormones.

pancreas, which secretes the hormone insulin in response. As cells of the liver take up glucose to store it as glycogen and the body cells take up glucose for energy, the blood glucose levels decline and the insulin release stops as blood glucose levels normalize.

In a positive feedback loop, a stimulus also begins the process, as when a nursing infant suckles at the mother's breast. The suckling sends an impulse to the hypothalamus, which in turn signals the posterior pituitary to release oxytocin. The oxytocin stimulates milk production and ejection from the

TABLE 33-1 Endocrine Glands: Their Hormones and Actions

Gland	Hormone	Action Produced
Hypothalamus (produces)	Antidiuretic hormone (ADH)	Stored and released by posterior pituitary
	Oxytocin (OT)	Stored and released by posterior pituitary
Anterior pituitary	Growth hormone (GH)	Promotes growth and tissue maintenance
	Melanocyte-stimulating hormone (MSH)	Stimulates pigment regulation in epidermis
	Adrenocorticotrophic hormone (ACTH)	Stimulates adrenal cortex to produce its hormones
	Thyroid-stimulating hormone (TSH)	Stimulates the thyroid to produce its hormones
	Follicle-stimulating hormone (FSH)	(F) Stimulates ovaries to produce ova and estrogen (M) Stimulates spermatogenesis
	Luteinizing hormone (LH)	(F) Stimulates ovaries for ovulation and estrogen production (M) Stimulates testes to produce testosterone
	Prolactin (PRL)	(F) Stimulates breasts to produce milk (M) Works with and complements LH
Posterior pituitary (releases)	Antidiuretic hormone (ADH)	Stimulates kidneys to retain water
	Oxytocin (OT)	Stimulates uterine contractions for labor and delivery
Pineal body	Melatonin	Regulates biological clock; linked to onset of puberty
Thyroid	T ₃ and T ₄	Protein synthesis and increased energy production for all cells
	Calcitonin	Increases bone calcium and decreases blood calcium
Parathyroid	Parathyroid hormone (PTH)	Agonist to calcitonin; decreases bone calcium and increases blood calcium
Thymus	Thymosin and thymopoietin	Both hormones stimulate the production of T lymphocytes
Adrenal cortex	Aldosterone	Stimulates body to retain sodium and water
	Cortisol	Decreases protein synthesis; decreases inflammation
Adrenal medulla	Epinephrine and norepinephrine	Prepare the body for stress; increase heart rate, respiration, and blood pressure
Pancreas (islets of Langerhans)	Alpha cells—glucagon	Increases blood sugar; decreases protein synthesis
	Beta cells—insulin	Decreases blood sugar; increases protein synthesis
Gonads: Ovaries (Female)	Estrogen and progesterone	Secondary sex characteristics; female reproductive hormones
Testes (Male)	Testosterone	Secondary sex characteristics; male reproductive hormone

mammary glands. Milk continues to be released as long as the infant continues to nurse.

► Hormone Production

LO 33.2

Hormones are produced in various organs and glands throughout the body. For example, the brain has several sites of hormone production, including the hypothalamus, pituitary gland, and pineal body. The pancreas, kidneys, stomach, and reproductive organs also produce important hormones.

The Hypothalamus

The hypothalamus is located in the diencephalon of the brain (see the chapter *The Nervous System*) and produces the hormones *oxytocin* and *antidiuretic hormone (ADH)*. These hormones are transported to the posterior pituitary, where they are stored and released as directed by the hypothalamus.

The Pituitary Gland

The pituitary gland, also known as the *hypophysis*, is located at the base of the brain and controlled by the hypothalamus. This gland is well protected by a bony structure called the *sella turcica*. The pituitary is divided into two lobes: the anterior lobe and the posterior lobe (see Figures 33-1 and 33-3).

Anterior Lobe of the Pituitary Gland The anterior lobe of the pituitary gland, also known as the *adenohypophysis*, secretes the following hormones:

- *Growth hormone (GH)*. As its name suggests, this hormone stimulates an increase in the size of the body's muscles and bones. It is important in childhood for growth. It also stimulates tissue repair. Growth hormone is also known as *somatotropin*.
- *Melanocyte-stimulating hormone (MSH)*. This hormone stimulates synthesis of melanin and its disbursement to the skin cells of the epidermis.

FIGURE 33-2 Positive and negative feedback loops in the endocrine system—the initial step in any feedback pathway is the stimulus. (a) A negative feedback loop occurs when the end product of a pathway turns off or slows down the pathway, whereas (b) a positive feedback loop is involved when the end product of a pathway stimulates further pathway activity.

- **Adrenocorticotropic hormone (ACTH).** This hormone stimulates the adrenal cortex to release its hormones.
- **Thyroid-stimulating hormone (TSH).** This hormone stimulates the thyroid gland to release its hormones.
- **Follicle-stimulating hormone (FSH).** In females, this hormone stimulates the production of estrogen by the ovaries. More significantly, FSH stimulates maturation of the ova (eggs) before ovulation. In males, it stimulates sperm production (spermatogenesis).
- **Luteinizing hormone (LH).** In females, this hormone stimulates ovulation (the release of an egg from the ovaries) and the production of estrogen. In males, it stimulates the production of testosterone.
- **Prolactin (PRL).** In females, this hormone stimulates milk production by the mammary glands. Because of this function, it is sometimes called the lactogenic hormone. In males, prolactin is known to enhance the functioning of LH.

FIGURE 33-3 Location of the pituitary gland.

Posterior Lobe of the Pituitary Gland The posterior lobe of the pituitary gland, also known as the *neurohypophysis*, secretes the following two hormones:

- *Antidiuretic hormone (ADH)*. This hormone stimulates the kidneys to conserve water. It therefore decreases urine output and helps to maintain blood pressure. You may find it easier to remember the purpose of this hormone by remembering your terminology word parts: *anti* = against, *dia* = complete, and *uresis* = urination.
- *Oxytocin (OT)*. In females, this hormone causes contractions of the uterus during childbirth. It also causes the ejection of milk from mammary glands during breast-feeding. In males, oxytocin stimulates the contraction of the prostate and vas deferens during sexual arousal.

The Thyroid Gland and Parathyroid Glands

The **thyroid gland** sits below the larynx (voice box) and consists of two lobes. The lobes are divided into follicles, which store some of the hormones this gland produces. Two major types of hormones produced by the thyroid gland are *thyroid hormones* and *calcitonin*. There are two main thyroid hormones: *triiodothyronine* (T_3) and *thyroxine* (T_4). The *T* stands for *thyroid*, and the numeral refers to the number of iodine atoms that are needed for each of these hormones to work properly.

Thyroid hormones increase cells' energy production, stimulate protein synthesis, and speed up the repair of damaged tissues. In children, they are important for normal growth and the development of the nervous system. Calcitonin lowers blood calcium levels by pulling excess calcium from the blood to activate osteoblasts to build new bone tissue.

Most people have four **parathyroid glands**. They are small glands embedded into the posterior surface of the thyroid gland. The only hormone secreted by the parathyroid glands is called *parathormone*, or *parathyroid hormone (PTH)*. This

hormone acts as an agonist to calcitonin by raising blood calcium levels through the activation of osteoclasts. Osteoclasts are bone-dissolving cells. When they dissolve bone, calcium levels in bone decrease as calcium is released into the bloodstream. This action raises blood calcium levels.

The Adrenal Glands

An adrenal gland sits on top of each kidney. It is divided into two portions: the adrenal medulla and the adrenal cortex. The adrenal medulla is the central portion of the gland and secretes *epinephrine* and *norepinephrine*. These hormones produce the same effects that the sympathetic nervous system produces. They increase heart rate, breathing rate, blood pressure, and all the other actions that prepare the body for stressful situations.

The adrenal cortex is the outermost portion of the adrenal gland. It secretes many hormones, but the two major ones are aldosterone and cortisol. *Aldosterone* stimulates the body to retain sodium, which helps it to retain water. This retention of fluid is important for maintaining blood pressure. *Cortisol* is released when a person is stressed. It decreases protein synthesis, and so it slows down the repair of tissues. Its advantage is that it also decreases inflammation, which decreases pain.

The Pancreas

The pancreas is located behind the stomach. It is an endocrine gland as well as an exocrine gland. It is considered an **exocrine gland** because it secretes digestive enzymes into a duct that leads to the small intestine. It is considered an endocrine gland because it contains structures known as **islets of Langerhans** that secrete hormones into the bloodstream. The islets of Langerhans consist of two types of cells: alpha cells, which secrete glucagon, and beta cells, which secrete insulin.

Insulin promotes the cells' uptake of glucose. It therefore reduces glucose concentrations in the bloodstream. It also

promotes the transport of amino acids into cells and increases protein synthesis. *Glucagon* increases glucose concentrations in the bloodstream and slows down protein synthesis.

Other Hormone-Producing Organs

The **pineal body** is a small gland located between the cerebral hemispheres. It secretes a hormone called *melatonin*. Melatonin helps to regulate circadian rhythms, which are more commonly known as the biological clock. Your biological clock helps you decide when you should be awake or asleep. Melatonin is also thought to play a role in the onset of puberty.

The **thymus** lies between the lungs. It secretes the hormones *thymosin* and *thymopoietin*, both of which promote the production of certain lymphocytes known as T lymphocytes. Refer to the chapter *The Lymphatic and Immune Systems* for further information about thymosin and the function of T cells.

Sometimes referred to as the **gonads**, the ovaries and testes are reproductive organs that secrete hormones. The ovaries release estrogen and progesterone, and the testes produce testosterone. The functions of these hormones are discussed in the chapter *The Reproductive Systems*.

The stomach and small intestine also secrete hormones. The stomach produces gastrin, and the small intestine releases

secretin and *cholecystokinin*. These hormones are discussed in the chapter *The Digestive System*.

The heart secretes a hormone called *atrial natriuretic peptide*, which regulates blood pressure. The kidneys secrete a hormone called *erythropoietin*, which stimulates blood cell production.

▶ The Stress Response

LO 33.3

Any stimulus that produces stress is termed a **stressor**. Stressors include physical factors such as extreme heat or cold, infections, injuries, heavy exercise, and loud sounds. Stressors also include psychological factors such as personal loss, grief, anxiety, depression, and guilt. Even positive stimuli such as sexual arousal, joy, and happiness can be stressors.

The body’s physiologic response to stress consists of a group of reactions called the *general stress syndrome*, which is primarily caused by the release of hormones. This syndrome results in an increase in the heart rate, breathing rate, and blood pressure. Glucose and fatty acid concentrations also increase in the blood, which leads to weight loss. Prolonged stress causes the release of cortisol. Cortisol slows down body repair because it prevents protein synthesis and inhibits immune responses, which is why a person under stress becomes more susceptible to illness.

PATHOPHYSIOLOGY

LO 33.4

Common Diseases and Disorders of the Endocrine System

Refer to Table 33-2 for a quick reference to diseases and disorders of the endocrine system. The table lists hormones according to the hyposecretion or hypersecretion of individual hormones. They are listed in “head-to-toe” order according to the organ that makes the hormone.

ACROMEGALY is a disorder in which too much growth hormone is produced in adults (see Figure 33-4).

Causes. This disorder is caused by an increased production of growth hormone or by a tumor of the pituitary gland.

Signs and Symptoms. The primary signs and symptoms include enlargement of the bones in the entire skull as well as in the hands and feet, and thickening of the skin. Other symptoms

TABLE 33-2 Endocrine System Diseases/Conditions: Quick Reference Guide		
Hormone	Hypo- or Hypersecretion	Disease or Condition
GH (somatotropin)	Hyposecretion (children)	Dwarfism
	Hypersecretion (children)	Gigantism
	Hypersecretion (adults)	Acromegaly
ACTH	Hyposecretion (adrenal cortex—cortisol)	Addison’s disease
	Hypersecretion (adrenal cortex—cortisol)	Cushing’s syndrome
ADH	Hyposecretion	Diabetes insipidus (dehydration)
	Hypersecretion	Edema, hypertension
T ₃ /T ₄	Hyposecretion (congenital/children)	Cretinism
	Hyposecretion (adults)—severe cases	Hypothyroidism and <i>myxedema</i>
	Hypersecretion (adults or children)	Graves’ disease (hyperthyroidism)
Glucagon	Hyposecretion	Hypoglycemia
	Hypersecretion	Hyperglycemia
Insulin	Hyposecretion	Hyperglycemia (diabetes mellitus)
	Hypersecretion	Hypoglycemia (hyperinsulinism)

(a)

(b)

FIGURE 33-4 Acromegaly is caused by the secretion of excessive growth hormone (GH) in adulthood. The face and hands are most notably affected, as seen in this individual at ages 16 and 30.
© Incredible Features/Barcroft Media/Getty Images

include headache, fatigue, profuse sweating, pain (especially in the arms and legs), gaps between the teeth, weight gain, excessive hair production, cardiovascular diseases, arthritis, and vision problems.

Treatment. Treatment includes medications to lower the production of growth hormone, radiation therapy to reduce the size of a pituitary tumor, and surgery to remove a pituitary tumor.

ADDISON'S DISEASE is a condition in which the adrenal glands, specifically the adrenal cortex, fail to produce enough corticosteroids. It affects about 1 in every 25,000 people (see Figure 33-5).

Causes. The cause of this disease is most often unknown. It may be caused by an autoimmune dysfunction. It can be caused

by cancer and other serious diseases that damage the adrenal glands.

Signs and Symptoms. The signs and symptoms may begin long before a diagnosis is made. They include weakness, fatigue, and dizziness after rising from a sitting or reclining position. Other symptoms include weight loss, muscle pain, lack of appetite, nausea, vomiting, diarrhea, and dehydration.

Treatment. Because this disease can be life-threatening, the first treatment is to administer corticosteroids. Medications or other hormones may be prescribed to help balance the levels of sodium and potassium.

CUSHING'S SYNDROME is also known as *hypercortisolism*. In this condition, a person produces too much cortisol (see Figure 33-6).

(a)

(b)

FIGURE 33-5 Addison's disease. (a) John F. Kennedy prior to being treated for Addison's disease. (b) In 1960, Kennedy's face shows the facial swelling that was one of the effects of cortisone treatment for Addison's disease.

Courtesy of the Cushing's Support and Research Foundation, www.CSRF.new and Kathy Carbone

Causes. This syndrome is caused by an excessive production of ACTH (a hormone that increases the production of cortisol), a tumor of the adrenal gland (the source of cortisol), a tumor of the pituitary gland (the source of ACTH), or the long-term use of steroidal hormones.

Signs and Symptoms. Common symptoms include a round, or full, face (“moon face”), a hump of fat between the shoulders (“buffalo hump”), thin arms and legs with a large abdomen, fatigue, thin skin, acne, frequent thirst (polydipsia), frequent urination (polyuria), mental disabilities, a loss of menstrual cycle in females (amenorrhea), high blood pressure (hypertension), high blood glucose levels (hyperglycemia), and body aches in the muscles, back, or head.

Treatment. The first treatment includes lifestyle changes, especially stopping the use of steroidal hormones. Radiation therapy or surgery may be needed to treat any tumors.

DIABETES INSIPIDUS is a condition in which the kidneys fail to reabsorb water, causing excessive urination. Diabetes insipidus is not related to diabetes mellitus, the pancreatic disorder causing hyperglycemia.

Causes. The primary cause is the hyposecretion of ADH.

Signs and Symptoms. These include excessive thirst, even with a more-than-adequate fluid intake. Other signs and symptoms include excessive urination and, in severe cases, muscle cramps and cardiac arrhythmias related to electrolyte imbalances caused by the excessive fluid loss.

Treatment. The primary treatment is increased fluid intake. Other treatments include surgery for any tumor of the pituitary that may cause the inadequate secretion of ADH. Changes in diet and medication help increase water retention.

DIABETES MELLITUS is a chronic disease characterized by high glucose levels in the blood (hyperglycemia). There are at least three different types of diabetes mellitus. Type 1 is referred to as *early-onset diabetes* or *insulin-dependent diabetes mellitus* (IDDM), and it often is diagnosed during childhood. Type 2 is the most common type and is often called *late-onset diabetes* or *noninsulin-dependent diabetes mellitus* (NIDDM). Historically this type of diabetes was primarily diagnosed in older adults but there has been a surge in the number of adolescents and teens being diagnosed with Type 2 diabetes. This surge has been linked to excessive weight and lack of exercise in the younger population. Gestational diabetes occurs only in pregnant women and is usually temporary, although a history of gestational diabetes has been found to put the patient at higher risk of developing Type 2 diabetes later in life. Women with gestational diabetes should be monitored closely for Type 2 diabetes. African Americans, Hispanics, and Native Americans are more likely to develop diabetes than any other ethnic groups.

Causes. This disease is caused by the production of too little or no insulin by the pancreas. Other causes include body cells having too few insulin receptors, obesity, high blood pressure, pregnancy, and high cholesterol levels in the blood.

Signs and Symptoms. There are many signs and symptoms of this disease. They include high levels of glucose in the blood, excessive

thirst (polydipsia), frequent urination (polyuria), fatigue, increased appetite, unexplained weight loss, blurry vision, impotence in men, nausea, skin wounds that heal slowly, high glucose and ketone levels in the urine, and lower extremity problems (due to poor circulation).

Treatment. Treatment includes daily injections of insulin, oral medications to increase insulin production, oral medications to increase the body’s sensitivity to insulin, frequent monitoring of glucose levels in the blood, and frequent monitoring of ketone levels in the urine. Lifestyle changes are important and should include reducing weight (especially if obese), changing eating habits, and getting regular exercise. Lifestyle changes to prevent injury to legs and feet may also be needed. More information on diet and treatment for diabetic patients may be found in the *Nutrition and Health* chapter.

Complications. Left untreated, diabetes can result in long-term and life-threatening complications. Blood vessels become thickened, which can damage vital organs, including the kidneys, eyes, heart, and brain. Long-term damage can result in kidney disease, blindness, and atherosclerosis (the buildup of fatty deposits in blood vessels). Circulation worsens, which not only affects organs but also may result in slower overall healing and ulcers that develop in the lower extremities, particularly the feet. Because of the body’s decreased ability to heal, these ulcers may require amputation of the affected foot and possibly part of the leg (below-knee amputation, or BKA). Further information on diabetic emergencies, including insulin shock and diabetic coma, may be found in the *Emergency Preparedness* chapter.

Go to CONNECT to see animation exercises about Type 1 Diabetes and Type 2 Diabetes.

DWARFISM is a condition in which too little growth hormone (somatotropin) is produced in childhood (see Figure 33-7).

Causes. This condition can be caused by an underproduction of the growth hormone during childhood, trauma to the pituitary gland, or a pituitary tumor.

Signs and Symptoms. Signs and symptoms include short height, abnormal facial features, cleft lip or palate, delayed puberty, headaches, frequent urination, and excessive thirst.

Treatment. Treatment is the administration of supplemental growth hormone.

GIGANTISM is a condition in which too much growth hormone is produced during childhood (see Figure 33-8).

Causes. This condition is caused by overproduction of growth hormone during childhood. It can also be caused by a tumor in the pituitary gland.

Signs and Symptoms. Very tall height, delayed sexual maturity, thick facial bones, thick skin, weakness, and vision problems are common symptoms.

FIGURE 33-7 Pituitary dwarfism is caused by hyposecretion of growth hormone.

© McGraw-Hill Education/Joe DeGrandis, photographer

Treatment. Treatment includes medications to reduce growth hormone levels, radiation therapy, and surgery to remove the tumor.

GOITER is an enlargement of the thyroid gland, causing (sometimes disfiguring) swelling of the neck (see Figure 33-9).

Causes. Typically, a simple goiter is caused by a deficiency of iodine in the diet. Iodine is needed for the thyroid to produce thyroid hormones.

Signs and Symptoms. These include overgrowth of the follicles of the thyroid gland, which causes enlargement of the gland and of the neck, and abnormal thyroid function tests (TFTs).

Treatment. The most common treatment is iodine supplementation in the diet. In the United States, salt contains iodine, so goiters are seldom seen. Because a goiter may not shrink even after adequate iodine is introduced into the diet, surgery may be required to remove some or most of the enlarged gland.

GRAVES' DISEASE is a disorder in which a person develops antibodies that attack the thyroid gland (see Figure 33-10). This attack causes the thyroid to produce too many thyroid

FIGURE 33-8 Gigantism results from hypersecretion of growth hormone.

© Eric Robert/Sygma/Corbis

hormones. Graves' disease is the most common type of hyperthyroidism in the United States.

Causes. This disease is caused by an overproduction of thyroid hormones. It is also considered an autoimmune disorder.

Signs and Symptoms. The most common signs and symptoms include exophthalmos (protrusion of the eyes) and goiter (thyroid

FIGURE 33-9 An iodine deficiency causes simple (endemic) goiter and results in high levels of TSH.

© Chris Pancewicz/Alamy RF

FIGURE 33-10 Signs of Graves' disease, a form of hyperthyroidism, include protruding eyes and goiter.

© Dr. M. A. Ansary/Science Source

enlargement). Other symptoms include insomnia, unexplained weight loss, anxiety, muscle weakness, increased appetite, excessive sweating, vision problems, and an increased heart rate.

Treatment. Treatment includes medications to reduce heart rate, sweating, and nervousness; radiation to destroy the thyroid gland; surgery to remove the thyroid gland (thyroidectomy); and supplemental thyroid hormones if the gland is destroyed or removed.

CRETINISM is an extreme form of hypothyroidism that is present prior to or soon after birth (see Figure 33-11).

Causes. The cause is hypothyroidism at birth (a congenital anomaly) related to the absence or malformation of the thyroid gland, abnormal formation of thyroid hormones, or pituitary failure that results in a lack of thyroid stimulation.

FIGURE 33-11 Cretinism is the result of an underactive thyroid gland during infancy and childhood.

© Mediscan/Alamy

Signs and Symptoms. Stunted growth, abnormal bone formation, mental retardation, low body temperature, and overall sluggishness are the primary signs and symptoms.

Treatment. The treatment is thyroid hormone replacement.

MYXEDEMA is a disorder in which the thyroid gland does not produce adequate amounts of thyroid hormone. It is a severe type of hypothyroidism that is most common in females over age 50.

Causes. Causes include the removal of the thyroid, radiation treatments to the neck area, and obesity. This disorder may be congenital.

Signs and Symptoms. Signs and symptoms include weakness, fatigue, weight gain, depression, general body aches, dry skin and hair, hair loss, puffy hands or feet, a decreased ability to taste food, abnormal menstrual periods, pale or yellow skin, a slow heart rate, low blood pressure, anemia, an enlarged heart, high cholesterol levels, and coma.

Treatment. Treatment consists of giving supplemental thyroid hormones intravenously or orally and closely monitoring the levels of thyroid hormones.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
33.1 Describe the general functions of hormones and the endocrine system.	Endocrine glands are ductless glands, releasing hormones directly into the bloodstream and tissues. The organs of the endocrine system produce hormones that regulate the chemical reactions within cells, controlling the functions of organs, tissues, and other cells. Hormone levels are controlled by positive and negative feedback loops.
33.2 Identify the hormones released by the pituitary gland, thyroid gland, parathyroid glands, adrenal glands, pancreas, and other hormone-producing organs and give the functions of each.	The pituitary gland releases the following hormones: GH, MSH, ACTH, TSH, FSH, LH, PRL, ADH, and OT. The thyroid gland releases calcitonin, T ₃ , and T ₄ , which are important in growth and protein synthesis. The parathyroid gland releases PTH, which balances the action of calcitonin. The adrenal medulla secretes epinephrine and norepinephrine, which work with the sympathetic nervous system. The adrenal cortex produces many hormones, but the two major ones are aldosterone and cortisol. The two types of hormone-releasing cells in the pancreas are alpha cells, which release glucagon, and beta cells, which release insulin. The pineal body releases melatonin; the thymus releases thymosin and thymopoietin; ovaries release estrogen and progesterone (females); and the testes (males) release testosterone. The kidneys produce erythropoietin, and the heart produces atrial natriuretic peptide. Each hormone's specific function may be found in Table 33-1.
33.3 Explain the effect of stressors on the body.	Stressors are stimuli that produce a stress response, a physiologic response to the stimulus that changes the body's functioning in some way.
33.4 Describe the causes, signs and symptoms, and treatments of various endocrine disorders.	The diseases and disorders of the endocrine system are as varied as the organs and hormone dysfunctions that cause them. An overview of these conditions is found in Table 33-2.

Recall Ken Washington from the beginning of the chapter. Now that you have completed this chapter, answer the following questions regarding his case:

1. What gland is likely to be causing Ken's problems?
2. Based on what you have learned in this chapter, what diagnosis do you think Dr. Buckwalter will have for Ken?

3. What treatment options are available?
4. What other condition is often caused by treating this condition, and how is it managed?

EXAM PREPARATION QUESTIONS

- (LO 33.1) Which of the following hormone types is also known as a tissue hormone?
 - Steroidal hormones
 - Nonsteroidal hormones
 - G-proteins
 - Prostaglandins
 - Thyroid hormones
- (LO 33.2) Which endocrine organ also has a digestive function?
 - Adrenal medulla
 - Adrenal cortex
 - Pancreas
 - Pineal body
 - Thymus
- (LO 33.2) Which hormone assists the kidneys in retaining fluid?
 - ACTH
 - ADH
 - PTH
 - FSH
 - MSH
- (LO 33.2) The numeral in “T₃” and “T₄” stands for the number of _____ atoms needed for the hormones to work properly.
 - Chloride
 - Potassium
 - Calcium
 - Iodine
 - Sodium
- (LO 33.4) From which endocrine disease did President John F. Kennedy suffer?
 - Cushing’s syndrome
 - Addison’s disease
 - Acromegaly
 - Hypothyroidism
 - Graves’ disease
- (LO 33.3) Which hormone is released when a person is under prolonged stress?
 - Glucagon
 - Aldosterone
 - Melatonin
 - Oxytocin
 - Cortisol
- (LO 33.2) Which of the following hormones is not produced by the anterior pituitary?
 - Growth hormone
 - Follicle-stimulating hormone
 - Oxytocin
 - Luteinizing hormone
 - Prolactin
- (LO 33.1) Nonsteroidal hormones require which of the following to turn on enzymes inside target cells?
 - Amino acids
 - Prostaglandins
 - Calcitonin
 - G-protein
 - Prolactin
- (LO 33.4) A condition in which the body produces too much cortisol is
 - Cushing’s syndrome
 - Graves’ disease
 - Myxedema
 - Gigantism
 - Diabetes insipidus
- (LO 33.4) When too much growth hormone is produced in adults, the result is
 - Dwarfism
 - Gigantism
 - Cretinism
 - Myxedema
 - Acromegaly

MEDICAL TERMINOLOGY PRACTICE

Analyze the following medical terms, presented throughout the chapter. Using a medical dictionary (or Appendix I) place a / mark between each word part. Define each word part and then define the whole word.

EXAMPLE: **aden/oma** = aden means “gland” + oma means “tumor”
ADENOMA means “tumor of a gland.”

- | | | |
|-------------------------|-----------------|-------------------------|
| 1. acromegaly | 5. hypothalamus | 9. parathyroid |
| 2. adrenocorticotrophic | 6. melanocyte | 10. thymopoietin |
| 3. antidiuretic | 7. natriuretic | 11. hyperparathyroidism |
| 4. exocrine | 8. nonsteroidal | 12. endocrine |

Special Senses

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Valarie Ramirez	8/4/19XX	Penicillin
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	829-78-462	Current medications: Cyclafem 7/7/7 Lipitor® 10 mg daily

Valarie Ramirez, a 33-year-old female, is brought to the office by her boyfriend because she has something in her eye. While riding her motorcycle yesterday, something flew up under her helmet visor. She has been using Visine® eye-drops, but when she woke up this morning, her eye felt worse. She says she thinks a tiny bug flew into her eye, but

© McGraw-Hill Education

she cannot get it out. She has tried flushing the eye with water, but it did not help. You notice her right eye is red and swollen. You prepare Valarie for the physician to examine her eye.

Keep Valarie in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 34, you will be able to:

- 34.1** Describe the anatomy of the nose and the function of each part.
- 34.2** Describe the anatomy of the tongue and the function of each part.
- 34.3** Describe the anatomy of the eye and the function of each part, including the accessory structures and their functions.
- 34.4** Explain the visual pathway through the eye and to the brain for interpretation.
- 34.5** Describe the causes, signs and symptoms, and treatments of various disorders of the eyes.
- 34.6** Describe the anatomy of the ear and the function of each part, and explain the role of the ear in maintaining equilibrium.
- 34.7** Explain how sounds travel through the ear and are interpreted in the brain.
- 34.8** Describe the causes, signs and symptoms, and treatments of various disorders of the ears.

KEY TERMS

- | | |
|-------------------------|---------------------|
| auricle | organ of Corti |
| cerumen | ossicles |
| choroid | oval window |
| cochlea | papillae |
| conjunctiva | refraction |
| cornea | retina |
| eustachian tube | semicircular canals |
| external auditory canal | sensory adaptation |
| gustatory cortex | tympanic membrane |
| labyrinth | vestibule |
| lacrimal apparatus | |

- I.C.4** List major organs in each body system
- I.C.5** Identify the anatomical location of major organs in each body system
- I.C.7** Describe the normal function of each body system
- I.C.8** Identify common pathology related to each body system including
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- V.C.9** Identify medical terms labeling the word parts
- V.C.10** Define medical terms and abbreviations related to all body systems

2. Anatomy & Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms, and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each system

3. Medical Terminology

- b. Build and dissect medical terms from roots/suffixes to understand the word element combinations that create medical terminology
- c. Apply various medical terms for each specialty

► Introduction

The special senses are smell, taste, vision, hearing, and equilibrium. They are called special senses because their sensory receptors are located within relatively large sensory organs in the head—the nose, tongue, eyes, and ears. Although the skin is also considered a sense organ (in fact, it is the largest sense organ), touch is not considered a special sense but rather a generalized one (refer to the chapter *The Integumentary System*). This chapter introduces the structure and function of the special sense organs.

As a medical assistant, you will likely be asked to assist with or perform examinations and treatments for common disorders of the eyes and ears. So you will need to understand how these important sense organs function.

► The Nose and the Sense of Smell LO 34.1

Smell receptors, also called *olfactory receptors*, are located in the olfactory organ, found in the upper part of the nasal cavity. See Figure 34-1. Smell receptors are chemoreceptors, which mean that they respond to changes in chemical concentrations. Chemicals that activate smell receptors must be dissolved in the mucus of the nose. Once smell receptors are activated, they send their information to the olfactory nerves. Refer to the chapter *The Nervous System* for more information about these nerves and the various parts of the brain. The olfactory nerves send the information along olfactory bulbs and tracts to different areas of the cerebrum in the brain. The cerebrum interprets the information as a particular type of smell.

Consider the following information related to our sense of smell.

- When individuals have either a “dry nose” or excessive mucus related to an upper respiratory tract infection or allergies, they may have trouble smelling. This is due to the inability of the chemicals (odors) that cause our sense of smell to be dissolved in the mucus of the nose.
- Humans have a relatively poor sense of smell compared to certain animals for two reasons. The chemicals (odors) that activate smell must diffuse all the way up the nasal cavity. Also, the human nose has fewer smell receptors than most animal noses.

FIGURE 34-1 The olfactory area (organ) is located in the superior part of the nasal cavity.

- Our sense of smell undergoes **sensory adaptation**, which means that the same chemical can stimulate smell receptors for only a limited amount of time. In a relatively short period of time, the smell receptors fatigue and no longer respond to the same chemical (odor), and it can no longer be smelled. Sensory adaptation explains why you smell a strong odor, such as perfume, when you first encounter it, but after a few minutes, you cannot smell it or may be less aware of it.

► The Tongue and the Sense of Taste

LO 34.2

Taste, or gustatory, receptors are located on taste buds. Taste buds are microscopic structures found mostly on the **papillae** (bumps) of the tongue. They cannot be seen with the naked eye. Some taste buds are also scattered on the roof of the mouth and in the walls of the throat. Recent research has indicated that a few taste receptors are also found in the lungs.

Each taste bud is made of taste cells and supporting cells (see Figure 34-2). The taste cells function as taste receptors, and the supporting cells simply fill in the spaces between the taste cells. Like the olfactory cells of smell, taste cells are

types of chemoreceptors. They are activated by chemicals found in food and drink that must be dissolved in saliva as part of the digestive process.

There are five types of taste sensations. Each sensation is recognized by a different type of taste cell:

- Sweet: taste cells with receptors that respond to “sweet” chemicals
- Sour: taste cells with receptors that respond to “sour” chemicals
- Salty: taste cells with receptors that respond to “salty” chemicals
- Bitter: taste cells with receptors that respond to “bitter” chemicals
- Umami: taste cells with receptors that respond to a savory, meaty sensation

For many years, it was thought that each type of taste cell was concentrated in a different area on the tongue. However, research has shown that all five types of taste cells are typically located within each taste bud. The sensory nerve at each taste bud is responsible for transmitting all of the taste sensations to the cranial nerves in the brain. There, the information is processed by the **gustatory cortex**, an area of the brain

FIGURE 34-2 (a) Taste buds are located on and near the papillae on the tongue. (b) Each taste bud has several taste cells corresponding to the various taste sensations.

that is responsible for interpreting taste sensations. The gustatory cortex integrates information from the taste cells with other information to provide a more complete interpretation. For example, eating spicy foods may activate pain receptors on the tongue that are interpreted by the gustatory cortex as “spicy.”

► The Eye and the Sense of Sight LO 34.3

The sense of sight comes from the eyes and is supported by visual accessory organs.

Vision

Your visual system consists of the eyes; the optic nerve, which connects the eyes to the vision center of the brain; and several accessory structures. If these parts of the system are healthy and normal, you are able to see normally.

Structure of the Eye

The eye is a complex organ that processes light to produce images. It is made up of three main layers, two chambers, and a number of specialized parts, as shown in Figure 34-3.

FIGURE 34-3 Anatomy of the internal eye—sagittal views depict (a) the three layers of the eye and (b) internal eye structures.

The Outer Layer The white of the eye—the *sclera*—is the tough, outermost layer of the eye. This layer, through which light cannot pass, covers all except the front of the eye. Here, the sclera gives way to the cornea in an area known as the corneal-scleral junction, or *limbus*. The **cornea** is a transparent area on the front of the eye that acts as a window to let light into the eye. Although there are no blood vessels in the sclera, numerous sense receptors detect even the smallest particles on the eyeball's surface.

The Middle Layer The **choroid** is the middle layer of the eye, which contains most of the eye's blood vessels. In the anterior part of the choroid are the iris and the ciliary body. The iris is the colored part of the eye. It is made of muscular tissue. As this tissue contracts and relaxes, an opening at its center (the pupil) grows larger or smaller. The size of the pupil regulates the amount of light that enters the eye. In bright light, the pupil becomes constricted (smaller). In dim light, it becomes dilated (larger).

The ciliary body is a wedge-shaped thickening in the eyeball's middle layer. Muscles in the ciliary body control the shape of the lens—making the lens more or less curved for viewing either near or distant objects. The lens is a clear, circular disk located just posterior to the iris. Because the lens can change shape, it helps the eye focus images of near or far-away objects. This process is called *accommodation*. Clouding and hardening of the lens, which often occur with aging, lead to visual changes in a condition known as *cataracts*. This condition will be discussed in more detail later in the *Assisting with Eye and Ear Care* chapter.

The Inner Layer The eye's inner layer consists of the **retina**. Nerve cells at the posterior of the retina sense light. The area where the optic nerve enters the retina is known as the optic disc. This area contains no sensory nerves itself and is referred to as the *blind spot*. There are two types of nerve cells, each named for its shape. *Rods* are highly sensitive to light. They function in dim light but do not provide a sharp image or detect color, only black, white, and shades of gray. They give you your limited “night vision” as well as peripheral vision. *Cones* function best in bright light. They are sensitive to color and provide sharper images. They are responsible for the ability to differentiate tones and hues of color. Deficiencies in the number or types of cones are responsible for the various types of color blindness, which is generally an inherited condition.

The Chambers of the Eye Each eyeball is divided into two chambers: anterior and posterior.

The Anterior Chamber The anterior chamber is in front of the lens and is filled with a watery fluid called *aqueous humor*. Aqueous humor provides nutrients to and bathes the structures in the anterior chamber of the eyeball. When there is an accumulation of aqueous humor, a person develops a visual condition known as *glaucoma*. This disorder will be discussed in more detail in the *Assisting with Eye and Ear Care* chapter.

The Posterior Chamber The posterior chamber of the eyeball is behind the lens and is filled with a thick, jelly-like fluid called *vitreous humor*. Vitreous humor keeps the retina flat and helps to maintain the eye's shape.

Visual Accessory Organs

Visual accessory organs assist and protect the eyeball. They include the orbits, eyebrows, eyelids and eyelashes, conjunctiva, lacrimal apparatus, and extrinsic eye muscles.

Eye Orbits and Eyebrows The eye sockets, or *orbits*, form a protective shell around the eyes. Eyebrows protect the eyes by reducing the chances that sweat and direct sunlight will enter them.

Eyelids and Eyelashes Each eyelid is composed of skin, muscle, and dense connective tissue. The muscle in the eyelid is called the *orbicularis oculi* and is responsible for blinking and squinting. Blinking the eyelids prevents the mucous membrane surface of the eyeball from drying. A moist eyeball surface is much less likely to grow bacteria than a dry one is. Blinking also protects the eyes, keeping foreign material from entering them with the assistance of the eyelashes, which catch foreign substances, including perspiration and dust.

Conjunctiva The **conjunctiva** is the mucous membrane that lines the inner surfaces of the eyelids and covers the anterior surface of each eyeball. Mucous membranes produce mucus, which keeps the surface of the eyeballs moist.

The Lacrimal Apparatus The **lacrimal apparatus** consists of lacrimal glands and nasolacrimal ducts (see Figure 34-4). *Lacrimal glands*, located on the lateral edge of each eyeball, produce tears. Tears are mostly water, but they

FIGURE 34-4 Lacrimal apparatus.

also contain enzymes that can destroy bacteria and viruses. Tears also have an outer, oily layer that prevents them from evaporating. *Nasolacrimal ducts*, located on the medial aspect of each eyeball, drain tears into the nose. When a person cries, the abundance of tears entering the nose produces the “runny nose” associated with crying.

Extrinsic Eye Muscles Extrinsic eye muscles are skeletal muscles that move the eyeball. Each eyeball has six extrinsic eye muscles attached to it that move the eyeball superiorly, inferiorly, laterally, or medially. (See Figure 34-5.)

► Visual Pathways

LO 34.4

The eye works much as a camera does. Light reflected from an object, or produced by one, enters the eye from the outside

and passes through the cornea, pupil, lens, and fluids in the eye. The cornea, lens, and fluids help focus the light onto the retina by bending it in a process known as **refraction**. As in a camera, light patterns carry an image of an object. The image is projected upside-down—on film in a camera and on the retina in an eye (see Figure 34-6). The retina converts the light into nerve impulses. These impulses are transmitted along the optic nerve to the brain. This nerve, which consists of about a million fibers, serves as a flexible cable connecting the eyeball to the brain.

Parts of the optic nerve fuse together, then cross at a structure called the *optic chiasm*—an x-shaped structure located at the base of the brain. The visual area in the occipital lobes of the cerebrum is responsible for interpreting vision. Because visual information crosses in the optic chiasm, about half of the visual information detected in each eye is interpreted on

FIGURE 34-5 The six extrinsic eye muscles move the eyeball superiorly, inferiorly, laterally, or medially.

FIGURE 34-6 Visual pathways. (a) Refraction is the process of bending light. (b) The image forms upside-down on the retina.

the opposite side of the brain. So half of what a person sees in the right eye is interpreted in the left side of the brain and vice versa, where it is brought together as one image. The brain interprets these impulses, turns the image right-side up, and “develops” a picture of the object from which the light originally came. See Table 34-1 for a summary of the parts of the eye and their functions.

TABLE 34-1 The Functions of the Parts of the Eye

Structure	Function
Aqueous humor	Nourishes and bathes structures in the anterior eye cavity
Vitreous humor	Holds the retina in place; maintains the shape of the eyeball
Sclera	Protects the eye
Cornea	Allows light to enter the eye; bends light as it enters the eye (refraction)
Choroid	Supplies nutrients and provides a blood supply to the eye
Ciliary body	Holds the lens; controls the shape of the lens for focusing
Iris	Controls the amount of light entering the eye
Lens	Focuses light onto the retina (accommodation)
Retina	Contains visual receptors
Rods	Allow vision in dim light; detect black, white, and gray images; detect broad outlines of images
Cones	Allow vision in bright light; detect colors; detect details
Optic nerve	Carries visual information (stimuli) from rods and cones toward the brain

The Aging Eye

With age, a number of changes occur in the structure and function of the eye, including the following:

- The amount of fat tissue diminishes; this loss may cause the eyelids to droop.
- The quality and quantity of tears decrease.
- The conjunctiva becomes thinner and may be drier because of a decrease in tear production.
- The cornea begins to appear yellow, and a ring of fat deposits may appear around it.
- The sclera may develop brown spots.
- Changes in the iris cause the pupil to become smaller, limiting the amount of light entering the eye.
- The lens becomes denser and more rigid; this trend reduces the amount of light that reaches the retina and makes focusing more difficult.
- Yellowing of the lens causes problems in distinguishing colors.
- Changes in the retina may make vision fuzzy.
- The ability of the eye to adapt to changes in light intensities may be reduced; glare can become painful as this ability diminishes.
- Night vision may be impaired.
- Peripheral vision is reduced, limiting the area a person can see and reducing depth perception.
- The vitreous humor breaks down, producing tiny clumps of gel or cellular material that cause floaters—dark spots or lines—that appear in a person’s field of vision.
- Rubbing of the vitreous humor on the retina produces flashes of light, or “sparks.”

Because of changes that impair vision—such as reductions in the field of vision, in depth perception, and in visual clarity—elderly people may fall more often than younger people.

EDUCATING THE PATIENT

Eye Safety and Protection

Almost 90% of all eye injuries could be prevented by eye safety practices or proper protective eyewear. You can educate patients about preventing eye injuries in the home, at work, and during recreational activities.

Eye Safety in the Home

Patients should follow these suggestions to protect their eyes in the home:

- Pad or cushion the sharp corners and edges of furniture and home fixtures.
- Make sure adequate lighting and handrails are available on stairs.
- Keep personal use items (like cosmetics and toiletries), kitchen utensils, and desk supplies out of the reach of children.
- Keep toys with sharp edges out of the reach of children. Also, make sure toys intended for older children are kept away from younger children.
- Remove dangerous debris from the lawn before mowing it.
- Wear safety goggles when operating any type of power equipment.
- Keep dangerous solvents, paints, cleaners, fertilizers, and other chemicals out of the reach of children.
- Never mix cleaning agents.

Eye Safety at Work

Approximately 15% of eye injuries in the workplace lead to temporary or permanent vision loss. Eye injuries at work can be diminished if patients take the following precautions:

- Choose safety eyewear according to the type of work being performed and the type of eye protection needed.
- Wear safety eyewear whenever there is a chance of flying objects from machines.
- Wear safety eyewear whenever there is possible exposure—by splash or splatter—to harmful chemicals, body fluids, or radiation.

Eye Safety During Sports and Recreational Activities

Eye injuries that commonly occur while playing a sport include scratched corneas, inflamed irises and retinas, bleeding in the anterior chamber of the eye, traumatic cataracts, and fractures of the eye socket. Wearing sports eye guards or goggles can prevent most sports eye injuries. These guards are recommended for baseball, basketball, soccer, football, rugby, and hockey. Protective goggles are recommended for mountain biking, motocross, and snow skiing. Virtually any type of contact sport requires appropriate eye protection.

PATHOPHYSIOLOGY

LO 34.5

Common Diseases and Disorders of the Eyes

As with all the body's organs, the sense organs are also susceptible to various diseases and disorders. Many eye injuries, however, are preventable. See the *Educating the Patient* feature for general tips about eye safety and protection. The following common diseases and disorders are specific to the eyes. Additional information about diseases and disorders of the eyes is found in the chapter *Assisting with Eye and Ear Care*.

ASTIGMATISM occurs when the lens has an abnormal shape or the cornea is unevenly curved. This abnormality causes blurred images in near or distant vision. Astigmatism may cause vertical or horizontal lines to appear out of focus.

Causes. This condition is considered to be congenital.

Signs and Symptoms. There are no symptoms with this condition other than blurred vision. However, it can be diagnosed during an ophthalmic (eye) exam.

Treatment. Treatment includes corrective lenses or surgery, such as photorefractive keratectomy (PRK) or, more commonly now, laser-assisted in situ keratomileusis (LASIK) to reshape the cornea (see Figure 34-7). This procedure—done on an outpatient basis under local anesthesia—involves reshaping the

cornea with a special laser. After LASIK surgery, 70% of patients have normal vision. A very small percentage of patients have postsurgical complications that cause their vision to worsen.

DRY EYE SYNDROME is one of the most common eye problems physicians treat. This syndrome results from a decreased production of the oil within tears, which normally occurs with age.

Causes. Dry eye can be caused by cigarette smoke; air conditioning; eye strain created by long hours at a computer monitor; some medications; contact lenses; hormonal changes associated with menopause; and hot, dry, or windy climates.

Signs and Symptoms. The common eye symptoms include burning, irritation, redness, itching, and excessive tearing.

Treatment. Artificial tears may provide relief to many patients, and drugs like Restasis® have helped patients with this condition make more of their own tears. People with this condition should drink 8 to 10 glasses of water a day and make a conscious effort to blink more frequently and avoid rubbing their eyes. In addition, punctal plugs can be inserted to trap tears on the eyes, which prevents the tears from entering the nasolacrimal duct and being drained.

ECTROPION is characterized by eversion (turning inside-out) of the lower eyelid.

FIGURE 34-7 LASIK laser vision correction procedure.

Causes. Aging and skin relaxation or scar tissue may cause this condition.

Signs and Symptoms. Common signs and symptoms include redness, irritation, and drying of the conjunctiva. Poor tear drainage through the nasolacrimal system may also be present.

Treatment. Surgery to repair the defect may be needed if the condition is bothersome to the patient.

ENTROPION is characterized by an inversion (turning outside-in) of the lower eyelid.

Causes. Aging and scar tissue may cause this condition.

Signs and Symptoms. Signs include irritation of the sclera as the lashes brush against it, which may lead to corneal ulceration or scarring.

Treatment. Surgery is the only treatment option to correct this problem.

NYSTAGMUS is rapid, involuntary eye movements.

Causes. Alcohol and some drug use may cause nystagmus. Inner ear disturbances may also result in involuntary eye movements. Brain lesions and injury (including those that may occur during birth) and cerebrovascular accidents (CVA), or strokes, may also cause nystagmus.

Signs and Symptoms. These include rapid, irregular eye movements that may be horizontal, vertical, or rotary, depending on the underlying cause of the nystagmus.

Treatment. Treatment focuses on the underlying cause of the disorder.

RETINAL DETACHMENT occurs when the layers of the retina separate. It is considered a medical emergency and, if not treated right away, leads to permanent vision loss.

Causes. Retinal detachment is rare; however, it is more common as people age. This disorder is sometimes caused by fluids that seep between layers of the retina; this occurs most commonly in nearsighted people. In diabetics, vitreous body or scar tissue pulls the retina loose. Another cause is eye trauma that causes fluid to collect underneath the layers of the retina.

Signs and Symptoms. Signs and symptoms include light flashes, wavy vision, a sudden loss of vision (particularly of peripheral vision), and a larger amount of floaters.

Treatment. When detected early, a hole in the retina can be “sealed” so that the retina does not completely detach. Sealing the hole is usually accomplished through the use of lasers or a procedure called cryopexy—surgical fixation with cold.

If the retina has already detached, some vision can often be restored with the following procedures.

- Pneumatic retinopexy, which involves injecting a gas bubble into the posterior segment of the eye; the pressure from the gas bubble flattens the retina, and the retina is later fixed in place with a laser
- Scleral buckle, which involves using a silicone band to hold the retina in place
- Replacing the vitreous body with silicone oil to reattach the retina

► The Ear and the Senses of Hearing and Equilibrium

LO 34.6

The organ of hearing is the ear. In addition to providing the sense of hearing, the ear aids the body in maintaining balance, or equilibrium. To assist with ear exams and procedures, you need to understand ear anatomy and the hearing process.

Structure of the Ear

The ear is divided into three parts: the external ear, middle ear, and inner ear (see Figure 34-8).

External Ear The external ear is composed of the **auricle**, or pinna, and the **external auditory canal**. The auricle is the flap of skin and cartilage that extends from the side of the head. It collects sound waves. The external auditory canal is

FIGURE 34-8 Anatomical regions of the right ear—the ear is divided into external, middle, and inner regions.

more commonly called the ear canal and is lined with skin that contains hairs and glands that produce **cerumen**, a wax-like substance commonly known as earwax. Cerumen lubricates the ear and protects it by trapping dirt, dust, and other microbes. This canal carries sound waves to the **tympanic membrane**, or eardrum. The tympanic membrane is a fibrous partition located at the inner end of the external auditory canal. It separates the external ear from the middle ear.

Middle Ear The middle ear includes the tympanic membrane, the ossicles, and the oval window. The tympanic membrane is thin and vibrates when sound waves hit it. On the other side of the tympanic membrane are three tiny bones called ear **ossicles**—the *malleus* (hammer), *incus* (anvil), and *stapes* (stirrup). When the tympanic membrane vibrates, it causes the ossicles to vibrate and hit a membrane called the **oval window**. The oval window ends the middle ear and marks the beginning of the inner ear.

The middle ear is connected to the throat by a tube called the **eustachian** (auditory) **tube**. This tube helps maintain equal pressure on both sides of the eardrum, which is important for normal hearing. Because the middle ear is connected to the throat by this tube, any throat infection can easily spread to the ear and vice versa.

Inner Ear The inner ear is a complex system of communicating chambers and tubes known as the **labyrinth**. It is

divided into three portions: **semicircular canals**, a **vestibule**, and a **cochlea** (see Figure 34-9). Each ear has three semicircular canals that detect the body's balance. The cochlea is shaped like a snail's shell and contains hearing receptors, including the **organ of Corti**, which is known as the organ of hearing. The vestibule is the area between the semicircular canals and the cochlea. Like the semicircular canals, it functions in equilibrium. When the head moves, the *perilymph* and *endolymph* fluids in the semicircular canals and vestibule move. This activates both equilibrium and hearing receptors. The equilibrium receptors send the information along vestibular nerves to the cerebrum for interpretation. The cerebrum can then advise the body if it needs to make any adjustments to prevent a fall.

When sound waves of different volumes and frequencies activate the hearing receptors in the cochlea, they send their information to auditory nerves. Auditory nerves (vestibulocochlear nerves) deliver the information to the auditory cortex in the cerebrum's temporal lobe. The auditory cortex interprets the information as sounds.

► The Hearing Process

LO 34.7

A sound consists of waves of different frequencies that move through the air. The external ear initiates sound conduction when it collects these waves and channels them to the tympanic membrane. Here, the waves make the tympanic

membrane vibrate. The vibrations, in turn, are amplified by the middle ear's ossicles. The amplified waves enter the inner ear and the cochlea. These waves cause tiny hairs that line the cochlea to bend. Movements of the hairs trigger nerve impulses. The auditory nerve transmits these impulses to the brain, where they are perceived as sound.

Sound waves are also conducted through the bones of the skull directly to the inner ear—a process called bone conduction. This alternative pathway for sound bypasses the external and middle ears. When you hear your own voice, the sound has reached your inner ear mainly through bone conduction. By comparing a person's ability to sense sounds by bone conduction and through the entire ear, doctors can often identify what part of the ear is causing a hearing problem. For example, if bone conduction is normal, a hearing problem likely involves the middle or external ear rather than the inner ear.

The Aging Ear

As a person grows older, a number of changes occur in the ear. The external ear appears larger because of continued cartilage growth and the loss of skin elasticity. The earlobe gets

longer and may have a wrinkled appearance. The glands that produce cerumen become less efficient, producing earwax that is much drier and prone to impaction. The ear canal also becomes narrower.

In the middle ear, changes in the eardrum cause it to shrink and appear dull and gray. The joints between the bones of the middle ear degenerate, so they do not move as freely. In the inner ear, the semicircular canals become less sensitive to changes in position, and this reduced sensitivity affects balance.

Problems with equilibrium make the elderly prone to falls. Some ear disorders, like hearing loss and Ménière's disease, are also more common in older individuals. Additional information about diseases and disorders of the ear are found in the chapter *Assisting with Eye and Ear Care*.

FIGURE 34-9 Right inner ear—the inner ear is composed of a bony labyrinth cavity that houses a fluid-filled, membranous labyrinth. Within the bony labyrinth are the vestibular organs for equilibrium and balance and the cochlea for hearing.

How to Recognize Hearing Problems in Infants

Hearing problems in infants are not easy to recognize. The following general guidelines can be used to teach parents how to identify normal hearing in infants. Any deviations from these guidelines may indicate a hearing loss.

Infants Up to 4 Months Old

- They should be startled by loud noises (barking dog, hand clap, and so on).
- When sleeping in a quiet room, they should wake up at the sound of voices.
- Around the fourth month of age, they should turn their head or move their eyes to follow a sound.
- They should recognize the mother's or primary caregiver's voice better than other voices.

Infants 4 to 8 Months of Age

- They should regularly turn their head or move their eyes to follow sounds.
- Their facial expressions should change at the sound of familiar voices or loud noises.
- They should begin to enjoy certain sounds such as rattles or ringing bells.
- They should begin to babble at people who talk to them.

Babies 8 to 12 Months of Age

- They should turn quickly to the sound of their name.
- They should begin to vary the pitch of the sounds they produce in their babbling.
- They should begin to respond to music.
- They should respond to the instruction “no.”

PATHOPHYSIOLOGY

LO 34.8

Common Diseases and Disorders of the Ears

The following common diseases and disorders are specific to the ears.

ACOUSTIC NEUROMA is a benign tumor of the cranial nerve involved in hearing and balance.

Causes. Acoustic neuroma is caused by a malfunction in a gene responsible for controlling the growth of Schwann cells—a type of neuroglial cell. (See the chapter *The Nervous System* for more information.) This gene is found on chromosome 22.

Signs and Symptoms. Gradual hearing loss in one ear is the most common symptom. Patients may also experience balance problems and tinnitus—ringing in the ears.

Treatment. Since acoustic neuromas often grow slowly, the physician may monitor the tumor if the patient is not experiencing severe symptoms. Large tumors or those causing severe symptoms may be treated with radiation therapy or surgical removal.

CERUMEN IMPACTION is a condition that consists of the buildup of earwax within the external auditory canal.

Causes. Cerumen impaction may be caused by improper cleaning of cerumen from the ear canal—using cotton-tipped applicators—or by overactive ceruminous glands producing more than the normal amount of cerumen.

Signs and Symptoms. The most common sign is some degree of hearing loss because of the blockage of sound waves. Some patients may also complain of ear pain, ringing in the ear, or a feeling that the ear is stopped up.

Treatment. Treatment includes ear irrigation to remove the blockage. Severely hardened cerumen may require an earwax softener such as Debrox® to soften and loosen the cerumen before the impaction can be removed.

HEARING LOSS, also known as deafness, is the loss of the ability to hear sounds at normal levels.

Causes. The two types of hearing loss are conductive and sensorineural. Conductive hearing loss is caused by a blockage of sound waves caused by cerumen impaction, a foreign body, otosclerosis (hardening of the stapes), or a tumor. Sensorineural hearing loss involves damage to the auditory nerve. Causes may include infection, medications, head trauma, and vascular disorders. In some cases, both types of hearing loss may be evident.

Signs and Symptoms. Patients may report gradual or sudden difficulty hearing voices, television, and other sounds within their environment. People around them may notice the need for increased volume when listening to television or the radio, or notice that the patient is speaking in a louder voice than necessary. Sudden hearing loss requires immediate medical attention.

Treatment. The treatment depends on the type of hearing loss involved. Any obstruction should be removed by irrigation or surgery if necessary. If hearing loss is a medication side effect, medication changes may be necessary. Hearing aids may be the answer for many patients. Cochlear implants may be an option for those not assisted adequately with hearing aids, as long as the auditory nerve remains intact.

OTITIS is inflammation of the ear. All three areas of the ear may be inflamed. **OTITIS EXTERNA** is infection of the outer ear, also known as swimmer's ear. The infection can be localized, as with a boil or abscess, or the entire ear canal lining can be affected. **OTITIS MEDIA** is a middle ear infection, and **OTITIS INTERNA** (labyrinthitis) is an inner ear infection.

Causes. Bacterial infections are often to blame for otitis externa. Otitis media often results from the spread of an upper respiratory infection from the throat that enters the eustachian tube and infects the middle ear. Labyrinthitis, especially the purulent or infective type, results from a spread of otitis media to the inner ear.

Signs and Symptoms. Pain in the ear with associated hearing loss is the primary symptom. Patients with otitis externa may also report itching and pus in the ear. Purulent (pus-containing) drainage may also occur in some forms of otitis media. Labyrinthitis often causes vertigo and nausea.

Treatment. Antibiotics or antifungals are given to treat the causative agent. Anti-inflammatory or pain medication and fever reducers may also be given to make the patient more comfortable. Antihistamines and anti-nausea medications may also be used to treat otitis interna.

OTOSCLEROSIS is the immobilization of the stapes within the inner ear, which is a common cause of conductive hearing loss.

Causes. Genetics seems to play a role. This disease occurs more frequently in females than in males.

Signs and Symptoms. These include a slow and progressive hearing loss that may be accompanied by tinnitus.

Treatment. Surgical removal of the stapes (stapedectomy) with insertion of a prosthetic stapes may result in at least a partial hearing restoration.

PRESBYCUSIS is hearing loss because of the aging process.

Causes. Factors like prolonged exposure to loud noise, infection, injury, certain medications, and some diseases are thought to be causes of presbycusis. Also, as part of the natural aging process, the auditory system deteriorates, resulting in a loss of hair cells (sensory receptors) in the organ of Corti. Changes in the blood supply to the ear and reduced function of the tympanic membrane or ossicles are also contributing factors.

Signs and Symptoms. Signs and symptoms include gradual, progressive hearing loss, usually of high-frequency sounds first. Typically both ears are affected and the patient has difficulty hearing high-pitched tones as well as normal conversation. Tinnitus may accompany this loss and the patient may become depressed and frustrated at the developing inability to communicate well as a result of the hearing loss.

Treatment. In most cases, hearing aids are prescribed to alleviate some of the hearing loss, although the condition itself is irreversible.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
34.1 Describe the anatomy of the nose and the function of each part.	Olfactory receptors—the sense receptors for the sense of smell—are found in the olfactory organ located in the upper part of the nasal cavity.
34.2 Describe the anatomy of the tongue and the function of each part.	Gustatory receptors are found on the taste buds, which are located on the papillae (bumps) of the tongue.
34.3 Describe the anatomy of the eye and the function of each part, including the accessory structures and their functions.	The eye is composed of three layers. The sclera is the outer, protective layer and includes the cornea. The middle, vascular layer is the choroid consisting of the iris, pupil, ciliary body, and lens and is the area of light regulation and focusing. The innermost layer is the retina containing the rods and cones, the optic nerve, and the optic disc. This is where the nerve impulse is picked up and taken to the brain for interpretation. The accessory organs are the orbits and eyebrows, eyelids and eyelashes, conjunctiva, lacrimal apparatus, and extrinsic eye muscles.
34.4 Explain the visual pathway through the eye and to the brain for interpretation.	The cornea, lens, and fluids focus light on the retina. The retina converts the image into nerve impulses, which the optic nerve transmits to the brain for interpretation.
34.5 Describe the causes, signs and symptoms, and treatments of various disorders of the eyes.	There are many common diseases and disorders of the eyes with varied signs, symptoms, and treatments. Some of these include astigmatism, dry eye syndrome, ectropion, entropion, nystagmus, and retinal detachment.

LEARNING OUTCOMES

KEY POINTS

34.6 Describe the anatomy of the ear and the function of each part, and explain the role of the ear in maintaining equilibrium.

There are three parts to the ear. The external ear includes the auricle, or pinna, and the external auditory canal to the tympanic membrane. The middle ear begins at the tympanic membrane and ends at the oval window and includes the ear ossicles. The inner ear is composed of the labyrinth and contains the organ of Corti as well as perilymph and endolymph—the fluids of hearing. The semicircular canals and vestibule in the inner ear function in the body's equilibrium and balance, sending impulses to the vestibular nerves, which take information to the cerebrum for interpretation.

34.7 Explain how sounds travel through the ear and are interpreted in the brain.

The outer ear collects sound waves and channels them to the tympanic membrane, which vibrates. The vibrations are amplified by the ear ossicles and enter the inner ear and cochlea. The movements of the hairs in the cochlea trigger nerve impulses, which the auditory nerve transmits to the brain.

34.8 Describe the causes, signs and symptoms, and treatments of various disorders of the ears.

There are many common diseases and disorders of the ears with varied signs, symptoms, and treatments. Some of these include acoustic neuroma, cerumen impaction, hearing loss, otitis, otitis externa, otitis media, otitis interna, otosclerosis, and presbycusis.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall Valarie Ramirez from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

- Describe the structures of the eye that might be affected by Valarie's motorcycle injury.
- What can you tell Valarie about protecting her eyes when she rides her motorcycle again?
- When you enter the examination room, you see Valarie and her boyfriend. You also notice a strong body odor smell and you are not sure where it is coming from. You consider reporting it to the licensed practitioner but after you have been in the room awhile the odor goes away. What, if anything, should you do about this odor? Why do you think the odor went away?

EXAM PREPARATION QUESTIONS

- (LO 34.1 and LO 34.2) Which of the special senses utilize chemoreceptors?
 - Smell and hearing
 - Taste and vision
 - Smell and taste
 - Vision and hearing
 - Smell and vision
- (LO 34.3) Which of the following is the other name for the corneal-scleral junction?
 - Optic chiasm
 - Limbus
 - Blind spot
 - Orbicularis oculi
 - Ciliary body

3. (LO 34.3) The changing of the lens shape is called
 - a. Astigmatism
 - b. Accommodation
 - c. Refraction
 - d. Focusing
 - e. Ectropion
4. (LO 34.3) The fluid in the anterior eye chamber is
 - a. Aqueous humor
 - b. Lacrimal humor
 - c. Vitreous humor
 - d. Orbital humor
 - e. Vestibular humor
5. (LO 34.2) Taste buds are found on the
 - a. Supporting cells
 - b. Papillae
 - c. Chemoreceptors
 - d. Esophagus
 - e. Gingiva
6. (LO 34.3) The mucous membranes that line each eye are known as
 - a. Lacrimal glands
 - b. Cornea
 - c. Conjunctivas

Infection Control Practices

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Ken Washington	12/1/19XX	Sulfa
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	891-12-743	U/A with microscopic exam and culture ordered

Ken Washington, a 61-year-old male patient, arrived today for a follow-up visit from a recent hospitalization for a stroke. Up until his hospitalization, he had hypertension but no other major health issues. He now has weakness in his left arm and leg and his speech is difficult to understand. His wife tells you that she has noticed some blood in the toilet after

© McGraw-Hill Education

he urinates. She also tells you that he has had some pain when he urinates and often only urinates a small amount. While he was in the hospital, Ken had a urinary catheter in place for 6 days.

Keep Ken in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 35, you will be able to:

- 35.1** Identify various healthcare-associated infections specific to the ambulatory care setting.
- 35.2** Describe methods of infection control, including those for preventing healthcare-associated infections.
- 35.3** Describe various methods of injection safety, including safety-engineered devices and work practice controls.
- 35.4** Summarize proper respiratory hygiene/cough etiquette practices utilized in the medical office.
- 35.5** Describe infection control procedures related to medical equipment.
- 35.6** Describe surgical site infections (SSIs) and ways to prevent them.
- 35.7** Discuss the procedures used in a medical office to sterilize surgical instruments and equipment.
- 35.8** Describe Centers for Disease Control and Prevention (CDC) requirements for reporting cases of infectious disease.

KEY TERMS

- | | |
|---|--|
| add-on safety feature | re-sheathing scalpel |
| autoclave | respiratory hygiene/cough etiquette |
| biological indicator | retractable needle |
| catheter-associated urinary tract infection (CAUTI) | self-blunting/blunt tip blood drawing needle |
| central line | self-sheathing needle |
| central line–associated bloodstream infections (CLABSI) | sterilization indicator |
| invasive procedure | surgical asepsis |
| medical asepsis | surgical site infection (SSI) |
| personal protective equipment (PPE) | |

- III.C.1 List major types of infectious agents
- III.C.3 Define the following as practiced within an ambulatory care setting:
 - (a) medical asepsis
 - (b) surgical asepsis
- III.C.4 Identify methods of controlling the growth of microorganisms
- III.C.5 Define the principles of standard precautions
- III.C.6 Define personal protective equipment (PPE) for:
 - (a) all body fluids, secretions, and excretions
 - (b) blood
 - (c) non-intact skin
 - (d) mucous membranes
- III.C.7 Identify Centers for Disease Control (CDC) regulations that impact healthcare practices
- III.P.1 Participate in bloodborne pathogen training
- III.P.2 Select appropriate barrier/personal protective equipment (PPE)
- III.P.4 Prepare items for autoclaving
- III.P.5 Perform sterilization procedures
- III.P.10 Demonstrate proper disposal of biohazardous material
 - (a) sharps
- III.A.1 Recognize the implications for failure to comply with Centers for Disease Control (CDC) regulations in healthcare settings

9. Clinical Procedures

- a. Practice standard precautions and perform disinfection/sterilization techniques
- e. Perform specialty procedures including but not limited to minor surgery, cardiac, respiratory, OB-GYN, neurological, gastroenterology

10. Medical Laboratory Procedures

- c. Dispose of biohazardous materials

► Introduction

As a medical assistant, you have a responsibility to protect the patient from exposure to infectious agents found in the medical environment. Following certain guidelines set forth by the Centers for Disease Control and Prevention (CDC) will help you meet this responsibility. These guidelines were introduced in the *Infection Control Fundamentals* chapter. In this chapter you will learn about the most common healthcare-associated infections (HAI) found in outpatient settings. A healthcare-associated infection is one acquired by a patient in a healthcare setting, sometimes called a nosocomial infection. The CDC uses the more current term *healthcare-associated infection*.

It is essential that you apply CDC guidelines and OSHA regulations in order to protect the patient, your coworkers, and yourself from exposure to infectious microorganisms. This requires strict adherence to standard precautions (including hand hygiene, which is covered in detail in the *Infection Control Fundamentals* chapter), proper selection and use of PPE, injection safety, and respiratory hygiene/cough etiquette. Also covered in this chapter are infection control practices related to medical equipment, sterilization procedures for surgical equipment, and reporting guidelines for infectious disease.

► Healthcare-Associated Infections LO 35.1

Increasingly, people are having surgery and complex diagnostic and treatment procedures in outpatient facilities instead of hospitals. This puts them at risk for infection caused by numerous pathogens found in the healthcare environment. No matter the level of care, all facilities must make infection control their top priority. As a medical assistant, you should be familiar with the most common types of healthcare-associated infections that occur in the outpatient setting, the risk factors associated with them, and ways to prevent them.

Risk Factors for Healthcare-Associated Infections

Patients can acquire healthcare-associated infections at hospitals, ambulatory surgical centers, physicians' offices, dialysis centers, and long-term healthcare facilities. Several common risk factors are associated with increased incidence of HAI in both outpatient and inpatient facilities:

- Use of catheters and other indwelling (fixed within the body for a period of time) devices
- Surgical procedures

- Healthcare environment contamination
- Communicable disease transmission (for example, influenza) between patients and healthcare workers
- Improper antibiotic use
- Immunocompromised patients

Common Healthcare-Associated Infections in Outpatient Settings

As you learned in the *Infection Control Fundamentals* chapter, touching is the most common means of transmission of infectious agents. As a medical assistant, your duties will include activities that require you to touch patients. If standard precautions are not followed during procedures that require touching, such as obtaining vital signs, changing a dressing, and removing sutures, you and the patient are at risk for infection. HAI are also associated with the devices used during medical procedures and testing, surgical site infections, and improper use of needles, syringes, and blood collection devices. You should use the utmost care when performing any patient procedure or test, no matter how small the risk.

Methicillin-Resistant *Staphylococcus aureus*

Methicillin-resistant *Staphylococcus aureus* (MRSA) is an infection caused by a specific type of staph bacteria. These bacteria have become resistant to most of the antibiotics used to treat the infection. For this reason, MRSA infections are difficult to treat and can have devastating consequences. Skin infections, the most common type of infection caused by MRSA, can begin as small bumps or pimples and quickly

develop into a large abscess (Figure 35-1). Additionally, MRSA infections can occur in the bloodstream, lungs, heart, bones, or joints. Anyone who has an **invasive procedure** (any procedure that requires entry into a body cavity or cutting into skin or mucous membranes) is at risk for MRSA infection.

The key to stopping the transmission of MRSA in the healthcare setting is proper hand hygiene and contact precautions (discussed in the *Infection Control Fundamentals* chapter). When assisting a patient with a known or suspected MRSA infection, put on gloves and a gown prior to entering the exam room. Once you are finished assisting with the patient care, remove your gloves and gown (in that order) before leaving the room. Perform proper hand hygiene immediately after removing your PPE.

***Clostridium difficile* Infection** *Clostridium difficile*, also known as C. diff, is a type of bacterium that causes diarrhea. It is of great concern in the elderly but can affect anyone taking antibiotics for prolonged periods of time and receiving medical care. It is transmitted by the fecal/oral route (touching a surface or patient contaminated with feces and then touching the mouth or mucous membranes). Symptoms of C. diff include watery diarrhea, fever, loss of appetite, nausea, and abdominal pain. Healthcare workers can transmit C. diff to patients by touching if proper hand hygiene is not followed. Since C. diff is found in feces, any surface or device contaminated with feces is a potential source of infection. This includes toilets, sinks, and rectal thermometers. For this reason, proper environmental cleaning in the healthcare facility is essential. Bathrooms and surfaces that may be contaminated with C. diff must be thoroughly decontaminated. You should wear gloves when assisting with a patient with known

FIGURE 35-1 A wound infected with MRSA is difficult to treat and can lead to tissue loss and sepsis.
CDC

or suspected *C. diff* infection or when cleaning and disinfecting the exam room and equipment. Alcohol does not kill *C. diff*; therefore, the CDC recommends handwashing with soap and water after caring for a patient with *C. diff*. If *C. diff* is diagnosed or suspected, alcohol hand disinfectants are not recommended. Surfaces and equipment that are likely to be contaminated should be cleaned and disinfected. A solution of 1:10 bleach or an EPA-approved disinfectant with sporicidal (able to kill spores) properties is recommended. (See the *Examination and Treatment Areas* chapter for more information about mixing a 1:10 bleach solution.)

Central Line–Associated Bloodstream Infections

Central line–associated bloodstream infections (CLABSI)

are caused by the entry of infectious microorganisms into the bloodstream by way of a **central line**. A central line is a catheter placed in a large vein, usually in the neck, chest, or groin, used to give fluids or medications. A central line differs from a normal intravenous (IV) catheter in several ways. IVs are usually placed for short amounts of time and are located in surface veins, whereas central lines are generally left in place for longer periods of time (weeks or months) and are placed in deep veins that are close to the heart. Though central lines are most often used in intensive care settings, they are also seen in patients receiving outpatient treatments such as chemotherapy.

Healthcare practitioners must follow strict infection control practices when inserting, checking, or changing a bandage of a central line:

- Following hand hygiene procedures
- Performing appropriate skin antisepsis at the site of insertion
- Allowing the skin prep agent to dry thoroughly before inserting the catheter
- Wearing gloves, gown, cap, and mask when inserting the catheter
- Using a large drape to cover the site during the procedure
- Washing hands before and after checking the central line

The CDC recommends removing the central line as soon as it is no longer needed.

As a medical assistant, you should instruct patients with central lines to contact the office immediately if

- The dressing covering the central line comes off or becomes wet or dirty.
- The site around the central line becomes red, hot, or sore.
- They have a fever or chills.

Additionally, you should instruct patients to

- Not touch the catheter insertion site.
- Avoid touching the tubing as much as possible.
- Not let visiting family and friends touch the tubing or site.
- Ask visiting family and friends to wash their hands when they arrive and before they leave.
- Tell the healthcare practitioner if they have concerns about the central line or the infection control practices of the healthcare personnel caring for them.

Catheter-Associated Urinary Tract Infections

Anyone who uses urinary catheters on a long-term basis is at risk for **catheter-associated urinary tract infections (CAUTI)**. Bacteria can enter the urinary tract by way of the catheter. The longer a catheter is in place, the more chance a patient has of contracting a CAUTI. For this reason, the CDC recommends that catheters be used for the least possible amount of time and only when necessary and no alternative is available. Catheters must be placed only by trained individuals using aseptic techniques. As a medical assistant, you can help patients with indwelling catheters to avoid CAUTI by teaching them to take the following precautions:

- Wash hands thoroughly with soap and water before and after touching the catheter.
- Ensure that the urine collection bag is always below the level of the bladder.
- Do not pull on the tubing.
- Do not kink or twist the tubing.

► Infection Control Methods

LO 35.2

As you learned in the previous section, there are numerous healthcare-associated infections that patients can be exposed to. The best way to keep patients from being infected is to consistently apply infection control methods. As a medical assistant, you must have a thorough knowledge of the two types of asepsis:

- **Medical asepsis**, or clean technique, is based on maintaining cleanliness to prevent the spread of microorganisms and to ensure that there are as few microorganisms in the medical environment as possible. The goal of medical asepsis is to reduce/control microorganisms after they leave the body.
- **Surgical asepsis**, or sterile technique, depends on a completely sterile environment that eliminates all microorganisms. The goal of surgical asepsis is to keep organisms from entering the body. (More information about surgical asepsis can be found later in this chapter and in the *Assisting with Minor Surgery* chapter.)

Medical asepsis and surgical asepsis are required by law. Each individual who works in a medical setting must recognize the importance of asepsis and strictly adhere to aseptic procedures in daily routines.

Medical Asepsis

Because the medical office can be a host to many pathogens, strict, controlled asepsis is crucial. All employees in the medical office must observe and practice the principles of asepsis to ensure a safe environment for patients and staff.

You can promote asepsis through vigilant cleanliness. Every day before patients arrive, you must inspect the office for any surfaces or objects that may be dirty or contaminated. Keeping the office clean reduces the number of microorganisms on surfaces.

Transmission from Healthcare Workers

There may be times when a healthcare worker has a serious infection that could be transmitted to a patient. OSHA has special recommendations for workers who perform procedures that could result in a patient's exposure to disease. Although the risk of a healthcare worker's transmitting an infection to a patient is small if OSHA standards are followed, these additional precautions are advised for high-risk procedures. High-risk procedures include the following:

- Those that are thought to have caused the transmission of infection from a medical worker to a patient in the past
- Those that may carry a high risk of infection, such as oral, obstetric, and gynecologic procedures
- Those that involve needles, especially if a needle is in a body cavity or a body space that is difficult to see and the healthcare worker's fingers are nearby (if the worker's skin is cut, the patient could be exposed to the worker's blood)

Workers who perform high-risk procedures should know their HIV and HBV status. HBV vaccination is strongly recommended. Also, workers who have skin conditions characterized by sores that secrete fluid should forgo direct patient care and the handling of equipment used for exposure-prone procedures until their condition has healed.

HIV or HBV infection should not necessarily keep an individual from practicing as a healthcare worker, but some special measures may need to be taken. A member of the medical staff who is infected with HIV or HBV should not perform procedures that might result in exposure for the patient without the advice of an expert review panel. This panel could include the healthcare worker's own physician, someone with expert knowledge about the transmission of infectious disease, a medical professional with expert knowledge about the procedures in question, public health officials, and a member of the infection control committee of the institution, if applicable.

The panel advises the worker on whether procedures may be performed. The advice includes requiring the worker to inform potential patients of the infection before the procedure. Each medical facility has policies in place outlining if and how patients will be notified of a healthcare professional's HIV or HBV status. The notification may be in writing from the panel, or the healthcare worker may speak directly to the patient. It is the healthcare worker's ethical duty to protect a patient from known exposure to bloodborne pathogens. However, the panel also must protect the healthcare worker's confidentiality if possible.

Although great controversy has surrounded the subject of required testing of all healthcare workers for HIV or HBV, no recommendations are in place for such testing. The risk of infection transmission from worker to patient is not considered great enough to justify the extensive resources that mandatory testing would require.

Office Procedures

Other physical aspects of the medical office that contribute to asepsis include

- A reception room that has designated waiting areas for well and sick people. If there is not enough space, sick patients

should be led immediately to an examination room. You may need to explain this policy to well people who have been waiting so that no one thinks other patients are getting preferential treatment.

- An office that is cleaned daily.
- An office that is well lit and ventilated, has no drafts, and has a temperature of approximately 72°F.
- Furniture that is kept in good repair and is replaced when necessary.
- A strict "no eating or drinking" policy in the lab, clinical, and other patient areas.
- Trash that is emptied as necessary, at least once daily.
- An insect-free environment.
- A sign stating that any safety or health hazard should be reported to the receptionist.
- A sign asking that patients use tissues for coughs or sneezes, put all waste in the trash can, and tell the receptionist if they are nauseated or have to use the restroom. (Ideally, the reception area should be equipped with a restroom for emergencies.) See Figure 35-2.

Asepsis During Medical Assistant Procedures

Many of the procedures you perform require aseptic techniques to prevent cross-contamination from one place to another. For instance, when opening a sterile container, you should rest its lid face-up instead of facedown. Placing it facedown contaminates the inside of the lid by picking up materials on the surface of the counter such as dust, dirt, blood, or body fluids, making it unsuitable to be put back on the sterile container. When administering tablets or capsules, you should pour them into the bottle cap or a cup rather than into your hand to prevent the transfer of microorganisms from your hand onto the medication. To prevent cross-contamination, you also must follow guidelines about the types of protective gear to wear during a procedure. (Personal protective equipment is discussed later in this chapter.)

Other Aseptic Precautions

You need to make certain precautions part of your daily routine. For example, take these safeguards:

- Avoid leaning against sinks, supplies, or equipment.
- Avoid touching your face or mouth.
- Use tissues when you cough or sneeze, and always wash your hands afterward.
- Whenever possible, avoid working directly with patients when you have a cold.
- Wear gloves and a mask if you have a cold and must work with patients.
- Stay home if you have a fever, and remain there until you have maintained a normal temperature for 24 hours.

Personal Protective Equipment

Employers are required by law to supply **personal protective equipment (PPE)** at no charge to their employees. PPE is any type of protective gear worn to guard against physical

FIGURE 35-2 Posting notices like this CDC poster in patient reception areas reminds patients to use tissues and cover their coughs to reduce the spread of infectious agents.

hazards. Healthcare workers require many kinds of personal protective equipment to do their jobs, including gloves, masks and protective eyewear or face shields, and protective clothing (Figure 35-3). During each procedure, keep in mind that the greater your chances of exposure to blood or other body fluids, the more pieces of PPE you will need to wear.

Gloves You must wear gloves for all procedures that involve exposure to blood, other body fluids, or broken skin. Several kinds of gloves for different situations are

- Disposable gloves—worn once and discarded. They cannot be used if they are torn, punctured, or otherwise damaged. Both examination and sterile gloves are disposable.
- Examination gloves—worn during procedures that do not require a sterile environment.

- Sterile gloves—used for sterile procedures such as minor surgery or urinary catheterization.
- Utility gloves—used when cleaning up. They are stronger than disposable gloves and may be decontaminated and reused if they show no signs of deterioration (including discoloration) after use.

Masks and Protective Eyewear or Face Shields You must wear appropriate masks and protective eyewear or face shields for procedures in which your eyes, nose, and mouth may be exposed. These procedures are ones that have a potential for spraying or splashing blood, such as surgery or dental procedures.

Protective Clothing If you are likely to have blood or body fluids sprayed or splashed on your clothing during a procedure,

FIGURE 35-3 Healthcare workers may need to use various types of personal protective equipment, including gloves, masks and protective eyewear or face shields, gowns, and other protective clothing.

© McGraw-Hill Education

you must wear a protective laboratory coat, gown, or apron. You also may wear a hair covering and/or shoe coverings for such procedures. You should always have a change of work clothing available in the event that blood or body fluids penetrate your regular clothes around or through the protective clothing.

Use of Multiple Types of PPE There may be situations that require you to wear more than one type of PPE. You may have to wear gloves, a gown, and a mask/face shield. The order in which you put these on and take them off is important. Since the gloves must go over the sleeves of the gown, the gown must go on first. The proper placement order for multiple PPE is gown, mask/face shield, and gloves. To reduce the possibility of cross-contamination, remove contaminated PPE in the opposite order; that is, gloves, mask/face shield, and gown. Procedure 35-1 demonstrates the correct method for removing contaminated gloves, and Procedure 35-2 demonstrates the proper method for removing a contaminated gown.

► Safe Injection Practices and Sharps Safety

LO 35.3

According to the World Health Organization (WHO), a safe injection does not cause injury to the patient, expose the provider to an avoidable risk, or create dangerous environmental/community waste. As a medical assistant, you may perform tasks, such as giving an injection, that require you to use needles or other sharp devices. During the course of these tasks,

you must protect the patient, your coworkers, and yourself by always adhering to safe injection and sharps safety practices, correctly using engineered sharps safety devices, and properly disposing of all sharps.

Safe Injection Practices

Recently, several large outbreaks of hepatitis B and hepatitis C were linked to outpatient settings in the United States. In response to these outbreaks, the CDC began the One and Only campaign to reemphasized and reinforce safe injection practices. The hallmark of the campaign is “One Needle One Syringe Only One Time,” reminding healthcare providers of the core of injection safety (Figure 35-4).

Recommendations for safe injection practices are part of the CDC’s *Guideline for Isolation Precautions: Preventing Transmission of Infectious Agents in Healthcare Settings 2007* and include the following:

- Use aseptic technique to avoid contamination of sterile injection equipment.
- Clean the top of medication vials with 70% isopropyl alcohol before withdrawing medications.
- Do not administer medications from a syringe to multiple patients.
- Use single-dose vials for parenteral medications whenever possible.
- Do not administer medications from single-dose vials or ampules to multiple patients or combine leftover contents for later use.
- If multi-dose vials must be used, both the needle or cannula and syringe used to access the multi-dose vial must be sterile.
- Do not keep multi-dose vials in the immediate patient treatment area and store in accordance with the manufacturer’s recommendations; discard if sterility is compromised or questionable.

FIGURE 35-4 Posting notices like this CDC One and Only poster reminds healthcare providers to follow safe injection practices.

Protecting Against Needlestick Injuries

OSHA estimates that there are approximately 800,000 needlestick injuries each year and 2% of these are most likely contaminated with human immunodeficiency virus (HIV). Needlestick injuries are completely preventable if you follow OSHA and CDC guidelines. In order to protect yourself from exposure to bloodborne pathogens when handling contaminated sharps, there are certain work practice controls that you should always follow:

- Do not recap needles unless there is no alternative. If no alternative exists, use a one-handed “scoop” technique.
- Do not bend or break needles.
- Use engineered safety devices whenever possible.
- Engage safety devices on needles and scalpels immediately after use.
- Dispose of sharps promptly using approved sharps containers.
- Have sharps containers easily accessible and as close as is feasible for patient safety.
- Use only OSHA-approved sharps containers.
- Do not overfill sharps containers.
- Close sharps containers before removing for disposal so that the contents do not spill.
- Never try to open a sharps container.

If you treat any needle or sharp device as if it were contaminated with a bloodborne pathogen, you have a greater chance of staying safe in the medical office.

Safety-Engineered Devices As you learned in the *Infection Control Fundamentals* chapter, work practice and engineering controls are the key to any needlestick safety program. There are a variety of safety-engineered devices (devices specifically engineered to reduce the incidence of needlesticks) available, including self-sheathing, retractable and self-blunting needles, re-sheathing scalpels, needleless devices, and needles with hinged safety features. According to OSHA, healthcare employers are required to evaluate new safety-engineered devices on a yearly basis and implement the

use of devices that reasonably reduce the risk of needlestick injuries. Employers must also solicit input from employees using the devices. As a medical assistant, you may be asked to evaluate and provide input about safety-engineered devices. It is important that you familiarize yourself with the various types and categories of safety-engineered devices.

Self-Sheathing Needles Self-sheathing needles have a sheath over the barrel of the syringe. After injecting the patient, the user slides the sheath forward over the needle and locks it into place. The sheath completely covers the needle and, once locked, cannot be slid back over the barrel (Figure 35-5a). The disadvantage of this type of safety device is that it requires two hands to activate.

Retractable Needles and Capillary Puncture Devices Syringes with **retractable needles** such as the BD Integra™ have a needle that retracts inside the barrel of the syringe after it is activated. Once the medication is injected, the plunger is pushed again and the needle withdraws inside the syringe (Figure 35-5b). Capillary puncture devices are single-use devices. The lancet retracts into the device after use, keeping it away from the user (Figure 35-5c).

Self-Blunting Needles Self-blunting, or **blunt tip, blood drawing needles** have a blunt tip that slides forward through the needle past the sharp point. This puts the sharp point of the needle below the blunt tip, removing the danger of a needlestick injury. Once the tube is filled with blood, the device can be activated while still in the patient’s vein and then removed (Figure 35-5d). Blunt tip devices are available for blood collection systems and winged steel needles.

Re-sheathing Scalpels Re-sheathing scalpels are single-use, disposable devices. After use, the healthcare practitioner slides a sheath over the blade, locking it in place. This is done using one hand, keeping the hands clearly away from the blade. Once the sheath is activated, the blade is safely out of the way and the blade is discarded in a sharps container (Figure 35-5e).

Needles with Add-On Safety Devices Injection, phlebotomy, and winged steel needles are available with **add-on safety features**. The device is either a hinged or sliding sheath attached to the needle. Activating the device is done with one hand by either moving the hinged sheath into place or sliding the sheath up and over the needle tip. This keeps the user’s hands behind the needle (Figure 35-5f).

► Respiratory Hygiene/Cough Etiquette Practices

LO 35.4

As you learned in the *Infection Control Fundamentals* chapter, many infectious diseases can be transmitted through respiratory droplets. Influenza, measles, whooping cough, and meningitis are all transmitted through respiratory droplets. A sneeze or a cough can send virus-filled droplets into the air and onto surfaces several feet away, putting anyone in

FIGURE 35-5 These are some of the safety-engineered devices available for use in healthcare settings.

the area at risk for exposure. Anyone who coughs or sneezes into her hand and then touches surfaces such as doorknobs, light switches, pens, papers, and exam tables is spreading viruses throughout the environment. As a medical assistant, you will need to take measures to protect patients, coworkers, and yourself from exposure to infectious agents transmitted by droplets. **Respiratory hygiene/cough etiquette** practices are simple and effective, commonsense approaches to defending yourself and others against infectious agents spread by respiratory droplets.

Using Reminders, Alerts, and Education to Stop the Spread of Respiratory Infection

Patients, their family members, and office staff all need to be reminded what they should do in case they are ill with a fever, cough, and sneezing. As mentioned earlier, posters should be displayed at the front door of the medical office reminding patients and their families to let the staff know if they suspect they have a respiratory illness. They may also be posted in exam rooms, bathrooms, and reception areas. The CDC has a variety of posters in several languages that may be obtained either free of charge or for a nominal fee. These posters should remind everyone to

- Cough and sneeze into a disposable tissue and immediately discard the tissue in an appropriate waste receptacle.
- Perform hand hygiene after coughing or sneezing to prevent the spread of germs.

Healthcare facilities should have tissues and alcohol-based hand rubs readily accessible in the reception area and

in exam rooms and laboratory areas. No-touch waste receptacles should be placed so that patients can easily access them. Additionally, give patients educational materials to take home, reminding them of ways to reduce the spread of respiratory infection to family and friends.

Masks, Isolation, and Decontamination

During local or regional outbreaks of respiratory illness, special precautions may be necessary. Ask patients who are coughing to wear a mask. Have masks readily available for patients, including in sizes that fit children. If possible, isolate patients who are coughing in a separate reception area. If this is not possible, ask patients who are coughing to sit at least 3 feet away from other patients. If a patient is coughing and has a high fever, ask him to put on a mask and move him to an exam room as quickly as possible.

When assisting with a patient who is coughing, put on a mask before entering the room. If a patient is coughing uncontrollably and there is considerable spray, you should wear gloves, a gown, and goggles. Perform hand hygiene before and after touching the patient or items or surfaces likely contaminated with respiratory droplets. Once the patient has left the room, you should wash your hands, put on gloves, and thoroughly clean and disinfect the exam room using an EPA-approved disinfectant of a 1:10 bleach solution. Include any surface the patient may have touched, including the doorknob, chair, desk, and exam table. If you are unsure if a patient touched a surface or an item, treat it as contaminated and clean and disinfect it. Medical equipment used to examine the patient should be disinfected according to office policy and procedure.

► Infection Control Practices with Medical Equipment

LO 35.5

There is a vast array of medical equipment used in patient care. Much of it is single use, meaning it is designed to be used for one patient during one test or procedure and then discarded in an approved container. Some equipment is reusable and must be appropriately disinfected or sterilized. This equipment is categorized based on the level of disinfection or sterilization necessary for reuse. Equipment is categorized as one of the following:

- Noncritical (such as blood pressure cuffs and reflex hammers)—these items only come in contact with intact skin and require low-level disinfection
- Semi-critical (such as endoscopes)—these items come in contact with mucous membranes and non-intact skin and require high-level disinfection at a minimum
- Critical (such as surgical instruments)—these items enter sterile tissue, body cavities, and veins and arteries and must be sterilized prior to use

CDC key recommendations for cleaning, disinfecting, and/or sterilizing medical equipment in ambulatory care settings include the following:

- Reusable medical equipment should be cleaned and reprocessed prior to use with each patient.
- Cleaning and reprocessing reusable equipment must be done according to the manufacturer's recommendations. If no recommendations exist, the device may not be considered appropriate for use on multiple patients.
- Equipment reprocessing should only be done by trained professionals.
- Copies of the manufacturer's reprocessing recommendations should be kept on file and posted in the reprocessing area.
- Equipment reprocessing should be routinely monitored.
- Personnel responsible for reprocessing equipment should wear appropriate PPE.
- Equipment must be cleaned to remove organic material (blood and tissue) prior to disinfection.
- Single-use equipment should never be used on more than one patient. It is not designed for reprocessing and reuse.

► Surgical Site Infections (SSIs)

LO 35.6

An infection that occurs after a surgical procedure at the site of surgery is considered a **surgical site infection (SSI)**. Approximately 3% of patients will develop an infection at the surgical site. The most common microorganism associated with SSIs is the bacterium *Staphylococcus aureus*; however, other bacteria also can cause infections at surgical sites. Most SSIs are endogenous—caused by microorganisms found on the skin or in the body of the patient—but they also can be exogenous—brought into the surgical site by medical instruments or equipment. Classifications of SSIs are dependent on the location and extent of the surgical wound. The three classifications are

- Superficial incisional—involves only the skin and subcutaneous tissue.
- Deep incisional—involves deep tissues such as fascia and muscle.
- Organ/space—excludes skin, fascia, and muscle; includes organs or body cavities.

In the medical office, you will most often see superficial incisional SSIs. Symptoms of superficial infections include

- Purulent drainage from the surgical wound.
- Positive wound culture from the site.
- Redness, swelling, and heat at the wound site.

Adherence to CDC guidelines, careful sterile technique during office procedures, and comprehensive patient education are the keys to preventing SSIs in the medical office. For more information about sterile technique, see the *Assisting with Minor Surgery* chapter.

Educating the Patient Prior to Surgery

Because most SSIs are endogenous, it is important that the patient be involved in reducing the occurrence of infection. You can help patients avoid an infection after surgery by giving them clear instructions about what to do before and after the surgical procedure:

Before the Procedure

- Report any previous postsurgical infections to the health-care practitioner.
- Stop smoking as soon as possible before the surgery.
- Tell your doctor if you have diabetes.
- Eat well and get plenty of rest.
- Shower with an antibacterial soap before the procedure.
- Do not shave near the surgical site before your surgery.
- Stay warm while on the way to the hospital by starting the car and getting it warm before leaving for your surgery, wearing warm clothes and covering with a blanket if needed.

The Day of Surgery

- Take any prescribed medications as instructed by your healthcare practitioner.
- Do not be afraid to speak up if you see healthcare workers fail to wash their hands.
- If a healthcare worker tells you she is going to shave the site with a razor, question her and ask to speak to the surgeon before allowing her to shave you. (The CDC recommends the use of clippers for hair removal, not razors.)

After the Surgery

- Do not allow family or friends to touch the wound.
- Care for the wound as directed by your healthcare practitioner.
- Wash your hands before and after caring for your wound.
- Call the office if you see any signs of infection.

You should give the patient all instructions in writing and verbally before the surgical procedure. Provide enough time for the patients to ask questions of you and the healthcare practitioner. Well-informed patients will be better prepared to care for themselves after surgery. Knowing how to care for their surgical wounds helps reduce the incidence of SSIs.

► Sterilization

LO 35.7

Sterilization is required for all instruments and supplies that will penetrate a patient's skin or come in contact with any other normally sterile areas of the body. Sterilization is also required for all instruments that will be used in a sterile field, even if they will not be used on a patient. An item is considered either sterile or unsterile. If you doubt the status of an item, consider it unsterile.

Before sterilizing an item, you must first sanitize it and, sometimes, disinfect it. Instruments and equipment that need to be sterilized include the following:

- Curettes (spoon-shaped instruments for removing material from a cavity wall or other surface)
- Instruments used during surgical procedures
- Suture removal instruments
- Vaginal specula (instruments used to enlarge the opening of the vagina and allow examination of the vagina and cervix)

Sterilize instruments and equipment by one of the following methods:

- Autoclaving
- Chemical (cold) processes

The Autoclave

The primary method for sterilizing instruments and equipment is the use of pressurized steam in an **autoclave** (Figure 35-6). This device forces the temperature of steam above the boiling point of water (212°F, or 100°C). Sterilization by autoclave is a widely accepted method of sterilization for two reasons:

1. Steam autoclaves can operate at a lower temperature than is required for dry heat sterilization. The moist heat from steam more quickly permeates the clean, porous wrappings in which all instruments are placed prior to loading them into the unit.
2. The moisture causes coagulation of proteins within microorganisms at a much lower temperature than is possible with dry heat. When cells containing coagulated protein cool, their cell walls burst; this kills the microorganisms.

General Autoclave Procedures In general, the sterilization process using an autoclave involves the following steps:

1. Prepare sanitized and disinfected instruments and equipment for loading into the autoclave by wrapping them in muslin, special porous paper, plastic bags, or envelopes and labeling each pack. (Include sterilization indicators.)

FIGURE 35-6 Steam autoclaving is the most common method of sterilizing instruments and equipment. Understanding the gauges and timer is essential to proper operation of an autoclave.

© Total Care Programming, Inc.

2. Check the water level in the autoclave; add distilled water if necessary.
3. Preheat the autoclave according to the manufacturer's guidelines. (Some models require putting instruments in before preheating.)
4. Perform any required quality control procedures (in addition to sterilization indicators in instrument packs).
5. Load the instruments and equipment into the autoclave. Allow adequate space around the items to ensure that steam reaches all areas.
6. Choose the correct setting based on the load type (unwrapped items, pouches, packs, liquids, and so on). If the autoclave is not automatic, set the autoclave for the correct time after the correct temperature and pressure have been reached.
7. Run the autoclave through the sterilization cycle, including drying time.
8. Remove the instruments and equipment from the autoclave.
9. Store the instruments and equipment properly for the next use. Rotate stored items so that packages with the oldest date are used first. Do not use packages past their expiration date.
10. Clean the autoclave and the surrounding work area.

During the autoclave process, assume the instruments and equipment are contaminated, and follow standard precautions:

- Wear gloves to avoid contamination by blood, body fluids, or tissues.
- Take measures to protect against needlesticks or cuts—for example, use forceps to handle sharps.
- Wash your hands thoroughly after all cleaning procedures.

Wrapping and Labeling All Items Wrap items in porous fabric, paper, or plastic before placing them in the autoclave. This material helps surround the items with the

correct levels of moisture and heat. Instruments and equipment to be used immediately after autoclaving can be placed on trays with material above and below the items. Items that must be stored in a sterile state for later use are wrapped and sealed before autoclaving. Refer to Procedure 35-3 at the end of this chapter, for wrapping and labeling instructions.

A number of products are available for wrapping items for sterilization. Muslin (140 count) may be used. However, because it is woven, it is more susceptible to contamination. All packs wrapped in muslin must be double wrapped. Other products include permeable paper, disposable nonwoven fabric, and clear plastic envelopes with one side made of permeable material. Figure 35-7 shows several common wrapping products and sterilization indicators.

Instruments that will be used together should be wrapped together to form a sterile pack. Wrap the pack loosely so that the steam can reach the instruments inside. After using a pack, consider all items (even those not used) unsterile and return them for sanitization, disinfection, and sterilization.

Clearly label each pack with a nontoxic marker to identify the item or items inside the wrapping and the person who completed the procedure. The label also must include the date to prevent use after expiring.

Preheating the Autoclave Check for solutions that may have boiled over and for deposits that may have formed on any of the inner surfaces. Make sure the water reservoir is filled to the proper level with distilled water. Also check the discharge lines and valves to make sure there are no obstructions. If lines or valves are blocked, air may remain trapped inside the chamber, rendering the load unsterile.

Following this inspection, preheat the unit according to the manufacturer's guidelines. Loading cold instruments into an overheated chamber can cause excess condensation, so be sure to understand and follow the preheating instructions.

FIGURE 35-7 Common wrapping products and sterilization indicators.

© McGraw-Hill Education

Understanding Autoclave Settings Modern autoclaves are designed to operate as automatically as possible; however, manual autoclaves are still used. Because you are responsible for the sterility of the items processed by the autoclave, you must be able to identify the various gauges and interpret their readings correctly.

Manual autoclaves have three gauges and a timer. The jacket pressure gauge shows the outer chamber's steam pressure. The chamber pressure gauge shows the inner chamber's steam pressure. The temperature gauge shows the temperature inside the inner, or sterilization, chamber. The timer allows you to control the number of minutes the load is exposed to the high-temperature, pressurized steam.

Exact temperature and pressure requirements vary with the model and type of autoclave, and with the instruments and packaging in the load. In general, the temperature must reach 250°F to 270°F (121°C to 132°C) and the chamber pressure gauge must show 15 to 30 pounds of pressure. Follow the manufacturer's instructions precisely for each autoclave load. Procedure 35-4, at the end of this chapter, describes the general steps to follow for running a load through the preheated autoclave.

Sterilization Indicators and Quality Control It is important to monitor all sterilization procedures. This is accomplished through the use of various types of indicators and quality control measures.

Sterilization indicators include special packages, tags, inserts, tapes, tubes, and strips that confirm the items in the autoclave have been exposed to the correct volume of steam at the correct temperature for the correct length of time. Several types of indicators are available (Figure 35-8).

For example, you place tags or inserts within the load, whereas you affix tapes to the outside of wrapped instrument packs. Indicators have designated areas or words that change color when the correct temperature, pressure, and proper length of time have been reached. Although it is generally acceptable to rely on indicators as a guarantee of sterility, in reality, they are only indicators that the load has been exposed to conditions that usually result in sterile surfaces. They do not guarantee that the autoclave contents are actually sterile.

Biological indicators—containing bacterial spores—are used as a quality control method to confirm that sterilization has occurred. Bacterial spores come in various forms, including strips, disks, and ampules. They are used because they are more resistant to common sterilization processes than non-spore-forming organisms. The general procedure for using biological indicators is as follows:

- Place a biological indicator in a load to be sterilized.
- Place another biological indicator outside the autoclave as a positive control.
- Run the load as usual.
- Interpret the biological indicator and positive control as directed by the manufacturer or send to an outside lab for processing.
- Incubate as recommended by the manufacturer.

FIGURE 35-8 Sterilization indicators are manufactured in various types, sizes, and shapes.

© McGraw-Hill Education

In general, place indicators in a sufficient number of places in the load so that you can be reasonably confident of the sterility of all items in the chamber. The following locations are suitable for indicator positioning:

- Within instrument packs
- On the outside of wrapped instrument packs
- Inside containers, especially those that cannot be positioned to allow steam to surround the item
- Near the air exhaust valve
- In any other areas into which steam might not be able to flow freely

For information on interpreting the results of a biological indicator, see the *Caution: Handle with Care* feature.

Preventing Incomplete Sterilization Although the autoclave is generally considered the simplest and most effective method for sterilizing instruments and equipment, certain pitfalls can cause incomplete sterilization. The four leading factors that cause incomplete sterilization are incorrect timing, insufficient temperature, overcrowding of packs, and inadequate steam levels. Once again, the manufacturer's guidelines provided with the autoclave unit are the best source of accurate information on how to operate it correctly.

Timing Guidelines After loading the autoclave, make sure the heating cycle lasts long enough to allow the steam to permeate all wrappings to reach the instruments and equipment inside. Timing for items to be sterilized should not be started until the unit has reached the proper temperature. Automatic

CAUTION: HANDLE WITH CARE

Interpreting the Results of a Biological Indicator

In some cases, you may be asked to interpret the results of a biological indicator. If the indicator exposed to the sterilization cycle is positive for bacterial growth, then sterilization has not occurred. The load should be held, the chemical indicators checked, and the biological indicator test repeated. If the second test is positive, have the sterilizer serviced. Once the sterilizer has been serviced, retest with three consecutive tests in an empty chamber. If all three tests are negative, the sterilizer can be returned to service. If the indicator exposed to the cycle shows no bacterial growth, check the growth of the positive control. The positive control should show bacterial growth

because it has not been exposed to the sterilization cycle. If there is no growth on the positive control, you should repeat the quality control procedure with biological indicators from another manufactured lot number. Record the results of each biological indicator monitoring procedure in the sterilization log. Biological indicators should be used at the following times:

- If a new type of packaging material is used
- If you have a new autoclave
- After autoclave maintenance or repair
- On a weekly basis as a general quality control measure

autoclaves have preset timing for each load type. You should keep up with the amount of time an automatic autoclave takes to complete a cycle, noting any differences between loads. Large differences in the amount of time it takes to complete a load cycle should alert you to a problem with the autoclave. Although following timing guidelines helps ensure sterilization, you also should use sterilization indicators.

If you have any doubt about the sterility of an instrument or a piece of equipment, do not use it. Instead, put it aside for another cycle of sanitization, disinfection, and sterilization. The risks to patients and to you are too great to take chances.

Temperature Guidelines The length of the sterilization cycle is only one factor that has an impact on the final quality of autoclave operations. If the autoclave is manual, the unit must operate at the correct temperature. Unit thermometers and sterilization indicators help confirm that correct temperatures have been reached.

Temperatures that are too high can cause problems as easily as those that are too low. If the temperature is too high inside the autoclave compartment, the steam does not have the correct level of moisture. The heat and moisture will not penetrate wrapped instrument packs, resulting in an unsterilized load.

If the temperature is too low, the steam contains too much moisture. Packs will be oversaturated and the drying cycle will be insufficient. Wet packs can easily pick up contaminants from surfaces they touch after you unload them from the autoclave. Common causes of low temperature are failing to preheat the autoclave chamber, loading cold instruments into an overheated chamber, opening the unit door too wide during drying, and overfilling the water reservoir. Always make sure you are familiar with the manufacturer's recommendations before running a load through an autoclave.

Overcrowding Packs or instruments placed in too close proximity in the autoclave chamber may not be sterilized because of the inability of the steam to penetrate or reach all surfaces.

Steam Level Guidelines Steam under pressure is necessary for sterilization. If the correct level of steam is not present during the autoclave cycle, items will not be sterile at the end of the cycle. It is vital that the unit force all air out of the chamber at the beginning of the sterilization cycle. It is also essential that you place items in the chamber in positions that will not cause the formation of air pockets.

To help ensure proper operation of the unit, check all release valves and discharge lines to make sure they are free from obstruction. Clogged valves and lines may prevent elimination of all air from the chamber.

To prevent the formation of air pockets, load items in the autoclave so that the steam can circulate freely around all sides of the items. Place containers on their sides to avoid trapping air. Besides allowing the free flow of steam, careful positioning helps ensure that all items dry thoroughly before you remove them from the autoclave.

Storing Sterilized Supplies Sterilized packs and instruments must be stored in a clean, dry location where they will not be disturbed or shuffled around. This keeps the wrapping material from being torn or otherwise compromised.

The method you use to wrap an item for sterilization determines the item's sterile shelf life. As a general rule, double-layer fabric- or paper-wrapped packages are considered sterile for 30 days. The manufacturers of other wrapping products provide their own guidelines for sterile shelf life.

Return items for sanitization, disinfection, and sterilization after the sterile shelf life period has elapsed. Do not reuse any wrapping or labeling products. Instead, open the packs or wrappings and process each item as if it had never been cleaned.

Cleaning the Autoclave and Work Area Clean the autoclave after each use to prevent accumulation of deposits that might affect the unit's operation. You may use a nontoxic all-purpose cleaner, although specific cleaning products are available for autoclave use.

You are responsible for ensuring that routine cleaning is done correctly and thoroughly. When you clean the unit, also check for signs of cracking or wear in gaskets, drain valves, and tubing. Check the level of distilled water in the reservoir. Service representatives who specialize in the maintenance of your unit should periodically clean and check all seals and gauges.

The work area around the autoclave unit should be divided into two clearly marked areas: one for nonsterile, not-yet-autoclaved items and one for sterile equipment as it is removed from the unit. Do not use supplies from one area in the other. Be sure to move any sterile packs or equipment to the correct storage areas when cleaning the counters and other work surfaces. If anything is spilled on a sterile pack or instrument, return the item for sanitization, disinfection, and sterilization.

Chemical Sterilization

Chemical, or cold, sterilization involves the use of liquids to eliminate microorganisms. It is used on instruments and equipment that are sensitive to heat and steam. For example, in a gastroenterologist's office, you may need to disinfect or sterilize an endoscope. Although each facility may perform this process differently, the process involves five steps after performing a leak test on the endoscope:

1. **Clean:** Mechanically clean internal and external surfaces, including brushing internal channels and flushing each internal channel with water and a detergent or enzymatic cleaners.
2. **Disinfect:** Immerse the endoscope in a high-level disinfectant or chemical sterilant and ensure contact of the germicide into all accessible channels, such as the suction/biopsy channel and air/water channel. Expose for the time recommended for specific products.
3. **Rinse:** Rinse the endoscope and all channels with sterile water, filtered water, or tap water (high-quality potable water that meets federal clean water standards at the point of use).

4. Dry: Rinse the insertion tube and inner channels with alcohol, and dry with forced air after disinfection and before storage. Drying the endoscope is essential to greatly reduce the chance of recontamination of the endoscope by microorganisms that may be present in the rinse water.
5. Store: Store the endoscope in a way that prevents recontamination and promotes drying, such as hanging it vertically.

► Reporting Guidelines for Infectious Diseases

LO 35.8

The CDC requires the reporting of certain diseases to the state or county department of health. This information, which is forwarded to the CDC, helps research epidemiologists control the spread of infection. Table 35-1 lists diseases that must be reported to the National Notifiable Disease Surveillance System of the CDC, through your state or county health department. When you report a communicable disease, you must fill out a report form. Your state health department may have a different form for each reportable disease. You must obtain the correct form and a disease identification number from the

health department every time you report a communicable disease. To fill out such a form, you need access to the following information:

- Disease identification (usually a code number as well as the name of the disease)
- Patient identification (including name, address, date of birth, sex, ethnic origin, and occupational or educational status) if required
- Infection history (date of onset, vaccination history, laboratory results)
- Reporting-institution information (name of person completing report, title, contact information)

Each state and each medical facility has specific guidelines for filling out such a form. Procedure 35-5 describes, in general, how to notify state and county agencies about reportable diseases. This procedure uses a paper form; however, electronic reporting may be available in the facility where you are employed.

Reporting guidelines also must be followed if a worker comes in contact with a substance that may transmit infection. These guidelines, which are explained in OSHA's Bloodborne Pathogens Standard, include reporting exposure incidents to employers immediately.

TABLE 35-1 The National Notifiable Disease Surveillance System

Anthrax	Giardiasis
Arboviral neuroinvasive and non-neuroinvasive diseases	Gonorrhea
Babesiosis	<i>Haemophilus influenzae</i> , invasive disease
Botulism, foodborne	Hansen disease (leprosy)
Botulism, infant	Hantavirus pulmonary syndrome
Botulism, other (wound and unspecified)	Hemolytic uremic syndrome, post-diarrhea
Brucellosis	Hepatitis A, acute
Chancroid	Hepatitis B, acute
<i>Chlamydia trachomatis</i> , genital infections	Hepatitis B, chronic
Cholera	Hepatitis B virus, perinatal infection
Coccidioidomycosis	Hepatitis C, acute
Cryptosporidiosis	Hepatitis C, past or present
Cyclosporiasis	HIV infection*
Dengue fever	• HIV infection, adult/ adolescent (age ≥ 13 years)
Dengue hemorrhagic fever	• HIV infection, child (age ≥ 18 months and < 13 years)
Dengue shock syndrome	• HIV infection, pediatric (age < 18 months)
Diphtheria	Influenza-associated pediatric mortality
Ehrlichiosis/anaplasmosis	Legionellosis
• <i>Ehrlichia chaffeensis</i>	Listeriosis
• <i>Ehrlichia ewingii</i>	Lyme disease
• <i>Anaplasma phagocytophilum</i>	Malaria
• Undetermined	Measles

(continued)

TABLE 35-1 The National Notifiable Disease Surveillance System

Meningococcal disease	Syphilis, congenital
Mumps	Syphilitic stillbirth
Novel influenza A virus infections	Tetanus
Pertussis	Toxic-shock syndrome (other than Streptococcal)
Plague	Trichinellosis (trichinosis)
Poliomyelitis, paralytic	Tuberculosis
Poliovirus infection, nonparalytic	Tularemia
Psittacosis	Typhoid fever
Q fever, acute and chronic	Vancomycin-intermediate <i>Staphylococcus aureus</i> (VISA)
Rabies, animal	Vancomycin-resistant <i>Staphylococcus aureus</i> (VRSA)
Rabies, human	Varicella (deaths only)
Rubella	Varicella (morbidity)
Rubella, congenital syndrome	Vibriosis
Salmonellosis	Viral hemorrhagic fevers, due to
Severe acute respiratory syndrome—associated coronavirus (SARS-CoV) disease	• Ebola virus
Shiga toxin—producing <i>Escherichia coli</i> (STEC)	• Marburg virus
Shigellosis	• Arenavirus
Smallpox	• Crimean-Congo hemorrhagic fever virus
Spotted fever rickettsiosis	• Lassa virus
Streptococcal toxic-shock syndrome	• Lujo virus
<i>Streptococcus pneumoniae</i> , invasive disease	• New world arena viruses
Syphilis, all stages	Yellow fever

*Acquired immunodeficiency syndrome (AIDS) (reclassified as HIV stage III).

PROCEDURE 35-1 Removing Contaminated Gloves

Procedure Goal: To remove gloves contaminated with blood, body fluids, or other potentially hazardous substances while avoiding cross-contamination of your hands or other surfaces

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue if performed correctly.

Materials: Contaminated gloves, lined trash container or bio-hazardous waste container

Method:

1. Using your dominant hand, grasp the palm of the glove of your nondominant hand.
2. Gently pull the glove downward off the nondominant hand, turning it inside out and holding it in your dominant hand.
3. Encase the removed glove completely in the dominant hand.

RATIONALE: *To contain any contaminants in the glove so that they are not accidentally transferred to your hands; encasing the glove also limits the possibility of splattering contaminants by flipping the glove*

4. Place the thumb or two fingers of the ungloved hand under the cuff of the remaining glove, being careful not to touch the outside of the glove with your bare hand.

RATIONALE: *The inside of the glove is most likely not contaminated.*

5. Pull the glove over your hand, turning it inside out over the other glove, leaving no outside surface exposed.
6. Throw the gloves away in the appropriate waste container.
7. Wash your hands.

PROCEDURE 35-2 Removing a Contaminated Gown

Procedure Goal: To remove a gown contaminated on the front and sleeves with blood, body fluids, or other potentially hazardous substances while avoiding cross-contamination of your hands, body, or other surfaces

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue if performed correctly.

Materials: Contaminated gown, lined trash container or biohazardous waste container

Method:

1. Unfasten ties from the neck, then from behind your back.

2. Peel the gown down and away from neck and shoulders, touching inside of gown only.

RATIONALE: *You should always move from clean to dirty to avoid cross-contamination.*

3. Continue pulling the gown down from the neck and shoulders and away from your body.
4. Turn gown inside out, making sure you do not touch the outer surface of the gown.

RATIONALE: *To avoid contaminating your hands*

5. Slowly fold or roll into a bundle and discard.
6. Wash your hands if they become visibly contaminated; otherwise use an alcohol-based hand sanitizer.

PROCEDURE 35-3 Wrapping and Labeling Instruments for Sterilization in the Autoclave

Procedure Goal: To enclose instruments and equipment to be sterilized in appropriate wrapping materials to ensure sterilization and to protect supplies from contamination after sterilization

OSHA Guidelines:

Materials: Dry, sanitized, and disinfected instruments and equipment; wrapping material (paper, muslin, gauze, bags, envelopes); sterilization indicators; autoclave tape; labels (if wrapping does not include space for labeling); and a waterproof pen

Method:

For Wrapping Instruments or Equipment in Pieces of Paper or Fabric

1. Wash your hands and don gloves before beginning to wrap the items to be sterilized.
2. Place a square of paper or muslin on the table with one point toward you. With muslin, use a double thickness. The paper or fabric must be large enough to allow all four points to cover the instruments or equipment you will be wrapping. It also must be large enough to provide an overlap, which will be used as a handling flap.
3. Place each item to be included in the pack in the center area of the paper or fabric “diamond.” Items that will be used together should be wrapped together. Make sure, however, that surfaces of the items do not touch each other inside the pack so that steam can penetrate every surface of all instruments in the pack. Inspect each item to ensure it is operating correctly. Place hinged instruments in the pack in the open position. Wrap a small piece of paper, muslin, or gauze around delicate edges or points to protect against damage to other instruments or to the pack wrapping.
4. Place a sterilization indicator inside the pack with the instruments. Position the indicator correctly, following the manufacturer’s guidelines (Figure a).
RATIONALE: *A sterilization indicator must always be placed inside the pack to ensure the contents have been sterilized properly.*
5. Fold the bottom point of the diamond up and over the instruments in to the center (Figure b). Fold back a small portion of the point (Figure c).
RATIONALE: *This “handle” will be used later, when the sterile pack is opened.*
6. Fold the right point of the diamond in to the center. Again, fold back a small portion of the point to be used as a handle (Figure d).
7. Fold the left point of the diamond in to the center, folding back a small portion to form a handle. The pack should now resemble an open envelope (Figure e).
8. Grasp the covered instruments (the bottom of the envelope) and fold this portion up, toward the top point (Figure f). Fold the top point down over the pack, making sure the pack is snug but not too tight.
9. Secure the pack with autoclave tape (Figure g). A “quick-opening tab” can be created by folding a small portion of the tape back onto itself. The pack must be snug enough to prevent instruments from slipping out of the wrapping or damaging each other inside the pack but loose enough to allow adequate steam circulation through the pack.
10. Label the pack with your initials and the date. Then list the contents of the pack. If the pack contains syringes, be sure to identify the syringe size(s).

FIGURE Procedure 35-3 Steps 4 through 9 Follow the sequence in this figure when you wrap instruments in a paper or fabric pack for sterilization in an autoclave.

RATIONALE: Dating helps you keep up with the date the pack expires. Items should be easily identified without opening the pack.

11. Place the pack aside for loading into the autoclave.
12. Remove gloves, dispose of them in the appropriate waste container, and wash your hands.

For Wrapping Instruments and Equipment in Bags or Envelopes

1. Wash your hands and put on gloves before beginning to wrap the items to be sterilized.

2. Insert the items into the bag or envelope as indicated by the manufacturer's directions. Hinged instruments should be opened before insertion into the package.

RATIONALE: This allows steam to penetrate inside the hinge.

3. Close and seal the pack. Make sure the sterilization indicator is not damaged or already exposed.

RATIONALE: If the sterilization indicator is damaged or already exposed, you have no way of knowing if the sterilization cycle was completed.

4. Label the pack with your initials and the date. Then list the contents of the pack. The pens or pencils used to label the pack must be waterproof; otherwise, the contents of the pack and date of sterilization will be obliterated.

RATIONALE: Dating helps you keep up with the date the pack expires. Items should be easily identified without opening the pack.

5. Place the pack aside for loading into the autoclave.
6. Remove gloves, dispose of them in the appropriate waste container, and wash your hands.

PROCEDURE 35-4 Running a Load Through the Autoclave

Procedure Goal: To run a load of instruments and equipment through an autoclave, ensuring sterilization of items by properly loading, drying, and unloading them

OSHA Guidelines:

Materials: Dry, sanitized, and disinfected instruments and equipment, both individual pieces and wrapped packs; oven mitts; sterile transfer forceps; and storage containers for individual items

Method:

1. Wash your hands and don gloves before beginning to load items into the autoclave.

2. Rest packs on their edges and place jars and containers on their sides.

3. Place lids for jars and containers with their sterile sides down.

4. If the load includes plastic items, make sure no other item leans against them.

RATIONALE: Pressure that results from the high temperatures can cause plastic items to bend or warp.

5. If your load is mixed—containing both wrapped packs and individual instruments—place the tray containing the instruments below the tray containing the wrapped packs.

RATIONALE: This arrangement prevents any condensation that forms on the instruments from dripping onto the wrapped packs and saturating the wrapping.

6. Close the door and start the unit. For automatic autoclaves, choose the cycle based on the type of load you are

running. Consult the manufacturer's recommendations before choosing the load type.

7. For manual autoclaves, start the timer when the indicators show the recommended temperature and pressure.
8. Right after the end of the steam cycle and just before the start of the drying cycle, open the door to the autoclave slightly (between $\frac{1}{4}$ and $\frac{1}{2}$ inch).

RATIONALE: *Opening the door more than $\frac{1}{2}$ inch causes cold air to enter the autoclave, possibly creating excessive condensation in the chamber. This condensation would cause incomplete drying. Consult the manufacturer's recommendations regarding opening the door. Some automatic autoclaves do not require opening the door during the drying cycle.*

9. Dry according to the manufacturer's recommendations. Packs and large items may require up to 45 minutes for complete drying.
10. Unload the autoclave after the drying cycle is finished. Do not unload any packs or instruments with wet wrappings, or the objects inside will be considered unsterile and must be processed again.

RATIONALE: *Wet wrappings can transfer bacteria from your hands to the interior of the pack.*

11. Unload each package carefully once they have cooled completely. Use sterile transfer forceps to unload unwrapped individual objects.
12. Inspect each package or item, looking for moisture on the wrapping, underexposed sterilization indicators, and tears or breaks in the wrapping. Consider the pack unsterile if any of these conditions is present.
13. Place sterile packs aside for transfer to storage.
14. Place individual items that are not required to be sterile in clean containers.
15. Place items that must remain sterile in sterile containers; close container covers tightly.
16. As you unload items, avoid placing them in an overly cool location; the cool temperature could cause condensation on the instruments or packs.
17. Remove gloves, dispose of them in the appropriate waste container, and wash your hands.

PROCEDURE 35-5 Notifying State and County Agencies About Reportable Diseases **WORK // DOC**

Procedure Goal: To report cases of infection with reportable disease to the proper state or county health department

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Communicable disease report form, pen, envelope, and stamp

Method:

1. Check to be sure you have the correct form. Some states have specific forms for each reportable infectious

disease or type of disease. CDC forms also may be used for reporting specific diseases.

2. Fill in all blank areas unless they are shaded (generally for local health department use).
3. Follow office procedures for submitting the report to a supervisor or physician before sending it out.
4. Sign and date the form. Address the envelope, put a stamp on it, and place it in the mail.

FIGURE Procedure 35-5 Step 1 Some states have specific forms for use with particular communicable diseases or diseases of a certain type.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
35.1 Identify various healthcare-associated infections (HAI) specific to the ambulatory care setting.	The most common HAI specific to the ambulatory care setting is MRSA. Other types of HAI that occur in outpatient settings include <i>Clostridium difficile</i> (C. diff), central line–associated bloodstream infections (CLABSI), catheter-associated urinary tract infections (CAUTI), and surgical site infections (SSIs).
35.2 Describe methods of infection control, including those for preventing healthcare-associated infections.	The two basic methods of infection control are medical asepsis (clean technique) and surgical asepsis (sterile technique). OSHA recommends that healthcare workers who work with high-risk patients know their HIV and HBV status, participate in an HBV vaccination program, and avoid direct patient contact if they have a skin condition characterized by sores that secrete fluid. Any healthcare worker who is HIV- or HBV-positive should not perform procedures that might expose a patient without first consulting an expert review panel.

LEARNING OUTCOMES	KEY POINTS
35.3 Describe various methods of injection safety, including engineered safety devices and work practice controls.	Injection safety procedures include always following strict aseptic procedures and standard precautions when administering injections. In addition, use safety-engineered devices whenever feasible.
35.4 Summarize proper respiratory hygiene/cough etiquette practices utilized in the medical office.	Post reminders for patients and staff to always cover their coughs and sneezes with a tissue and properly dispose of the tissue in an appropriate waste container. When assisting with a patient who has symptoms of a respiratory infection, ask patients to wear masks and use isolation precautions to stop the spread of infections.
35.5 Describe infection control procedures related to medical equipment.	Multi-use medical equipment should be properly cleaned, disinfected, and sterilized according to the manufacturer's recommendations before use with every patient. Single-use medical equipment should be properly disposed of and never reused with a different patient.
35.6 Describe surgical site infections (SSIs) and ways to prevent them.	A surgical site infection (SSI) is an infection that occurs after a surgical procedure at the site of the surgery. The signs of an SSI include purulent drainage, heat and redness at the site, and fever. Giving patients clear instructions about what to do before and after surgery and always following surgical aseptic procedures reduces the incidence of SSI.
35.7 Discuss the procedures used in a medical office to sterilize surgical instruments and equipment.	Instruments and equipment that must be sterilized before use should be sanitized to remove blood and gross tissue and then sterilized either in an autoclave or by chemical means.
35.8 Describe Centers for Disease Control and Prevention (CDC) requirements for reporting cases of infectious disease.	The CDC requires the reporting of certain diseases to the state or county department of health, which then reports the information to the National Notifiable Disease Surveillance System of the CDC.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall Ken Washington from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. Is it significant that Ken had a urinary catheter in place for 6 days while he was in the hospital?
2. Dr. Buckwalter plans to send Ken home with a urinary catheter in place. What information can you give him to help him prevent infection?
3. You note on the chart that Dr. Buckwalter wants to see Ken again in 2 days. You ask Ken to schedule an appointment for that time. Ken's wife states that they are going out of town for a week and will not be able to return until after that time. What should you tell Ken about making an appointment for more than a week?

EXAM PREPARATION QUESTIONS

- (LO 35.2) When opening a sterile container, you should place the lid
 - On the sterile field
 - Facedown on the counter
 - On a separate sterile field
 - In your opposite hand
 - Face-up on the counter
- (LO 35.1) Which of the following best describes a CAUTI?
 - An infection at the site of surgery
 - An infection caused by microorganisms entering the bladder by way of a catheter
 - A blood infection caused by a central line
 - A procedure to stop bleeding
 - A skin infection caused by antibiotic-resistant bacteria
- (LO 35.4) All of the following are considered good respiratory hygiene *except*
 - Isolating patients with respiratory infections in a separate reception area
 - Placing a mask and goggles on anyone with symptoms of a respiratory infection
 - Performing hand hygiene after coughing or sneezing
 - Asking patients who are coughing to sit at least 3 feet away from other patients
 - Immediately discarding used tissues into appropriate waste containers
- (LO 35.6) A superficial incisional surgical site infection is one that involves
 - Only the skin and subcutaneous tissue
 - Organs and body cavities
 - Muscles and fascia
 - Bones and joints
 - Intestinal tissue
- (LO 35.8) All of the following are reportable diseases *except*
 - Hantavirus
 - Giardiasis
 - Chickenpox
 - Adenovirus
 - Malaria
- (LO 35.6) Which of the following is the term for surgical site infections caused by microorganisms found on the skin?
 - Remote
 - Exogenous
 - Purulent
 - Endogenous
 - Extrinsic
- (LO 35.1) A procedure that requires entry into a body cavity or cutting into skin or mucous membranes is known as
 - Infectious
 - Systemic
 - Invasive
 - Internal
 - Vital
- (LO 35.3) Self-blunting, or blunt tip, blood drawing needles have
 - A device that slides through the lumen of the needle past the sharp point
 - A sheath that slides over the needle and locks
 - A needle that retracts into the syringe
 - A needle that automatically breaks off after removing from the patient
 - A needle with a hinged safety cover
- (LO 35.7) The sterile shelf life of a paper-wrapped surgical pack is
 - 1 month
 - 1 year
 - 6 months
 - 2 months
 - 14 days
- (LO 35.2) Another name for medical asepsis is
 - Sterile technique
 - Aseptic principles
 - Safe technique
 - Clean technique
 - Surgical cleaning

SOFT SKILLS SUCCESS

Recall Ken Washington from the case study at the beginning of the chapter. While you are giving Ken Washington care instructions for urinary catheterization, his wife states that she is not happy that Ken has to have another urinary catheter. She tells you that she thinks that the “man in the hospital” did not insert his urinary catheter properly and that is what has caused Ken’s problem. She asks you if you think it is possible that Ken was “damaged” at the hospital when

he had his urinary catheter inserted. What should you tell Ken’s wife?

Go to PRACTICE MEDICAL OFFICE and complete the module Admin: Check Out - Privacy and Liability.

Patient Interview and History

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Peter Smith	3/28/19XX	NKA
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	428-69-544	Sleep study scheduled with Metro Sleep Specialists

Peter Smith, a 73-year-old male with mild Type 2 diabetes, calls to schedule an appointment. He states that he is feeling very anxious and fatigued and is having difficulty eating and sleeping. He arrives at the clinic with his wife and needs to check in.

© Image Source/Getty Images RF

During the patient interview, he states that he wakes up in the middle of the night almost nightly. He also has many nights when he cannot even fall asleep. In addition, he has lost about 8 pounds in the last month. His symptoms started when his son died 6 months ago.

Keep Mr. Smith in mind as you study this chapter. There will be questions at the end of the chapter

based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 36, you will be able to:

- 36.1** Identify the skills necessary to conduct a patient interview.
- 36.2** Recognize the signs of anxiety; depression; and physical, mental, or substance abuse.
- 36.3** Use the six Cs for writing an accurate patient history.
- 36.4** Carry out a patient history using critical thinking skills.

KEY TERMS

- | | |
|----------------|-----------------|
| addiction | restatement |
| clarification | subjective data |
| mirroring | substance abuse |
| objective data | verbalizing |
| reflection | |

- I.P.3** Perform patient screening using established protocols
- I.A.1** Incorporate critical thinking skills when performing patient assessment
- I.A.2** Incorporate critical thinking skills when performing patient care
- V.C.2** Identify types of nonverbal communication
- V.C.4** Identify techniques for overcoming communication barriers
- V.C.15** Differentiate between adaptive and non-adaptive coping mechanisms
- V.C.16** Differentiate between subjective and objective information
- V.P.1** Use feedback techniques to obtain patient information including:
 - (a) reflection
 - (b) restatement
 - (c) clarification
- V.P.2** Respond to nonverbal communication
- V.P.3** Use medical terminology correctly and pronounced accurately to communicate information to providers and patients
- V.A.1** Demonstrate
 - (b) active listening
 - (c) nonverbal communication
- X.P.2** Apply HIPAA rules in regard to:
 - (a) privacy
 - (b) release of information
- X.P.3** Document patient care accurately in the medical record
- X.P.4** Apply the Patient's Bill of Rights as it relates to:
 - (a) choice of treatment
 - (b) consent for treatment
 - (c) refusal of treatment
- X.A.1** Demonstrate sensitivity to patient rights

- 3. Medical Terminology**
 - d. Define and use medical abbreviations when appropriate and acceptable
- 4. Medical Law and Ethics**
 - a. Follow documentation guidelines
 - b. Institute federal and state guidelines when releasing medical records or information
 - f. Comply with federal, state, and local health laws and regulations as they relate to healthcare settings
 - g. Display compliance with Code of Ethics of the profession
- 5. Psychology of Human Relations**
 - a. Respond appropriately to patients with abnormal behavior patterns
 - c. Intervene on behalf of the patient regarding issues/concerns that may arise, i.e. insurance policy information, medical bills, physician/provider orders, etc.
- 9. Clinical Procedures**
 - b. Obtain vital signs, obtain patient history, and formulate chief complaint
- 11. Career Development**
 - b. Demonstrate professional behavior

► Introduction

As a medical assistant, it is your job to prepare the patient and the patient's chart before the physician enters the exam room to examine the patient. You are the first contact with the patient in the exam room. How you conduct yourself during those first few moments can make a major difference in the patient's attitude and perception of the medical office. The patient must cooperate fully to provide the information the physician needs for an accurate diagnosis and successful treatment. Conducting the patient interview and recording the necessary medical history are essential to the practitioner's exam process.

► The Patient Interview and History LO 36.1

The first step in the exam process is the patient interview. A well-conducted initial interview in the exam room helps establish a beneficial relationship between you and the new patient while providing a detailed exchange of pertinent information. Subsequent interviews with established patients may take less time; however, all patient interviews require good communication skills.

When you interview a patient, you will ask the patient (or an attending family member) for specific information about the reason for his or her visit. If the visit is for a medical problem, you will ask about his or her symptoms

and determine the patient's chief complaint. The chief complaint is a subjective statement made by the patient describing the patient's most significant symptoms or signs of illness. Medicare and most insurers require this information. When a patient makes an office visit for a routine checkup, you will ask the patient about general health and lifestyle and about any changes in health status since the last visit.

A patient's medical and health history is the basis for all treatment rendered by the practitioner. The history also provides information for research, reportable diseases, and insurance claims. The information contained on the chart becomes a legal record of the treatment rendered to the patient. It must be complete and accurate to be a good defense in case of legal action. Document all information regarding the patient precisely and accurately.

Patient Rights, Responsibilities, and Privacy

It is important to remember that all the data you obtain are subject to legal and ethical considerations. Most states have adopted a version of the American Hospital Association's (AHA) Patient's Bill of Rights, written in 1973 and revised in 1992. Although AHA has replaced this bill of rights with "The Patient Care Partnership: Understanding Expectations, Rights, and Responsibilities," each state encourages health-care workers to be aware of and provide for the patient's rights. Familiarize yourself with the information about patient rights contained in the following list. All patients have the right to

- Receive considerate and respectful care.
- Receive complete and current information concerning his or her diagnosis, treatment, and prognosis.
- Know the identity of physicians, nurses, and others involved with his or her care as well as know when those involved are students, residents, or trainees.
- Know the immediate and long-term costs of treatment choices.
- Receive information necessary to give informed consent prior to the start of any procedure or treatment.
- Have an advance directive concerning treatment or be able to choose a representative to make decisions.
- Refuse treatment to the extent permitted by law.
- Receive every consideration of his or her privacy.
- Be assured of confidentiality.
- Obtain reasonable responses to requests for services.
- Obtain information about his or her healthcare and be allowed to review his or her medical record and to have any information explained or interpreted.
- Know whether treatment is experimental and be able to consent or decline to participate in proposed research studies or human experimentation.
- Expect reasonable continuity of care.
- Ask about and be informed of the existence of business relationships between the hospital and others that may influence the patient's treatment and care.

- Know which hospital policies and practices relate to patient care, treatment, and responsibilities.
- Be informed of available resources for resolving disputes, grievances, and conflicts, such as ethics committees or patient representatives.
- Examine his or her bill and have it explained, and be informed of available payment methods.

Medical assistants also should know that patients have certain responsibilities when they seek medical care. Patients are responsible for

- Providing information about past illnesses, hospitalizations, medications, and other matters related to their health status. If an incorrect diagnosis is made because a patient fails to give the physician the proper information, the physician is not liable.
- Participating in decision making by asking for additional information about their health status or treatment when they do not fully understand information and instructions.
- Providing healthcare agencies with a copy of their written advance directive if they have one.
- Informing physicians and other caregivers if they anticipate problems in following a prescribed treatment.
- Following the physician's orders for treatment. If a patient willfully or negligently fails to follow the physician's instructions, that patient has little legal recourse.
- Providing healthcare agencies with necessary information for insurance claims and working with the healthcare facility to make arrangements to pay fees when necessary.

Additionally, in April 2003, enforcement of the Health Insurance Portability and Accountability Act (HIPAA) began. If this act is not followed, individual healthcare workers can be subject to fines up to \$250,000 and 10 years in jail. The privacy standards of this act ensure the following:

- Healthcare facilities must provide patients with a written notice of their practices regarding the use and disclosure of all individually identifiable health information.
- Healthcare facilities may not use or disclose protected health information for any purpose that is not in the privacy notice.
- Patient consent is required when protected information is used or disclosed for purposes of treatment, payment, or health operations.
- Written authorization is required for other types of disclosures.
- Hospitals must make the privacy notice available either prior to or at the time of the delivery of care.
- A privacy notice must be posted in a clear and prominent location within the hospital facility.

Communicating with Professionalism

Remember, the first impression you make with patients in the exam room can be everlasting, as it can affect the way patients view the entire office's practice, including the physicians. As a medical assistant, communicating with professionalism is key. In addition to your awareness of patient rights, responsibilities, and privacy, your overall professionalism and poise

can be a direct result of your verbal communication skills. If you use improper language skills, such as poor grammar or slang, or appear to have sloppy body language, you may give the patient the perception that you are not educated or intelligent. Your communication skills will have a direct impact on your career. Take care and pride in what you know and how you communicate. Think before you speak or react and you will learn to avoid communication pitfalls.

Interviewing Skills

To conduct a successful patient interview and obtain history and health information, you will need to apply a variety of skills, including the following:

- Using effective listening
- Being aware of nonverbal clues and body language
- Using a broad knowledge base
- Summarizing to form a general picture

Using Effective Listening Listening attentively is one of the most important skills you will need for a successful interview. When you listen to what the patient is saying, you not only listen for details but also try to get an overall view of the patient's situation. As you become more experienced in conducting patient interviews, these skills will improve. One way to be a good listener is to hear, think about, and respond to what the patient has said. This technique is called *active listening*. Passive listeners simply sit back and hear. When you are an active listener, you look at the patient, pay attention, and provide feedback. For example, you may use the technique of **restatement**. Simply repeat what the patient says, in your own words, back to the patient. This helps to ensure that you have understood the meaning of the patient's words.

Being Aware of Nonverbal Clues and Body Language Verbal communication is the asking and answering of questions. To conduct a successful interview, you also must be aware of nonverbal communication. The patient's tone of voice, facial expression, and body language are examples of nonverbal communication. These signs often communicate more than words could ever say. For example, a patient who has difficulty making eye contact may be embarrassed by some symptoms and may need your extra patience and encouragement to report symptoms fully. A child or adolescent may deny or exaggerate pain. Pay attention to the patient's facial expression and how much the patient guards the area in question.

Using a Broad Knowledge Base To conduct a successful interview, you must have a broad knowledge base so that you can ask questions that will elicit the most meaningful information about the patient. You must take every opportunity to expand your knowledge base by learning more about medical terminology, anatomy and physiology, symptoms, and diseases.

Summarizing to Form a General Picture You will gather a variety of subjective and objective data as you conduct a patient interview. You must consider the relative importance of each piece of information so that you can summarize the data to formulate a general picture of the patient. It is always

a good idea to repeat back a summary of information to the patient. This will ensure that all important data are recorded. Patients will sometimes forget to add something, and repeating the summary may jog their memory.

Interviewing Successfully

One of the main goals of the patient interview is to give the patient an opportunity to fully explain, in her own words, the reason for the current office visit. These eight steps will help you conduct a successful interview.

1. Do your research before the patient interview.
2. Plan the interview.
3. Approach the patient and request the interview.
4. Make the patient feel at ease.
5. Conduct the interview in private without interruptions.
6. Deal with sensitive topics with respect.
7. Do not diagnose or give a diagnostic opinion.
8. Formulate the general picture.

Doing Research Before the Patient Interview Before the interview, review the patient's medical record for history, medications, and chronic problems (for example, diabetes or high blood pressure). Note whether the patient has family problems that might have an impact on health issues. Make sure that all currently ordered diagnostic testing, laboratory work, and consultation results are in the chart. If you discover that you are missing a result, you have some time to retrieve it from the facility while the patient is in the office.

Planning the Interview Develop an interview plan by having a general idea of the questions you will ask. For example, if a patient is being treated for high blood pressure, you might ask about headaches or tinnitus (ringing in the ears), which are common signs of high blood pressure. Planning the interview helps you maintain your focus and ensures that you will obtain all the necessary information.

It is important to be organized before the interview takes place. Follow the office policies when gathering patient information. For example, you may record the patient's height, weight, and vital signs before you begin the interview. Make sure that you follow office policy on the types of information you will need to ask the patient during the interview. For example, some physicians prefer that you record the patient's medication list before the exam, whereas others prefer to record the medication list themselves. Planning for the types of information that you need to collect will save time for the visit itself.

Approaching the Patient and Requesting the Interview Ask the patient for permission before conducting the interview. You may need to explain that questions about the reason for the visit and the patient's current health situation are necessary to plan the most effective care. It is more courteous to seek permission to ask questions than to say that you "need to take a history." Asking permission helps the patient feel more comfortable and emphasizes the importance

of the interview process. It also makes the patient feel more like a participant in the medical care being provided.

Making the Patient Feel at Ease Using certain words or phrases known as icebreakers can help set the stage for the interview. Icebreakers put the patient at ease and create a relaxed atmosphere. Examples of icebreakers include acknowledging the patient's reason for the visit, introducing yourself, and commenting about the weather. Icebreakers that also convey a sincere and sensitive interest in the patient are asking the patient how she prefers to be addressed and clarifying the pronunciation of a difficult name.

Another way to convey an image of a professional who is sensitive to the patient's needs is to sit with the patient and appear relaxed. By appearing relaxed, you help the patient relax and encourage a more open and comfortable interview. Eye contact is important when interviewing a patient. Sometimes patients will feel intimidated if they are forced to look up at you. If the patient

sits in a chair, then it is best that you sit; if the patient sits on the examining table, then it is appropriate to stand while recording the visit. Remember, if you are entering data into an electronic record, there is a patient in the room with you. If you pay more attention to inputting information into the computer than looking at and speaking with your patient, she may feel as if she is just another patient and not an individual being cared for by you.

Conducting the Interview in Private Without Interruptions After setting the stage for the interview, ensure privacy by showing the patient to a private room or area or by closing the door if the patient is already in a private room. You can then begin to ask relevant questions. Some approaches are more effective than others, as shown in Table 36-1. Listening carefully to the patient's responses may lead you to ask questions other than those in your interview plan.

Developing a rapport with the patient is essential. Keep the atmosphere relaxed, do not rush, maintain eye contact, and

TABLE 36-1 Methods of Collecting Patient Data

Effective Methods	Characteristics
Asking open-ended questions	Requires more than a yes or no answer; allows the patient to more fully explain the situation, resulting in more relevant data. Instead of asking, "Do you have a cough?" ask, "Can you tell me about your symptoms?"
Asking hypothetical questions	Allows you to determine the patient's knowledge of the situation and whether it is accurate. For example, ask a patient who has been prescribed nitroglycerin for chest pain, "What would you do if you had chest pain?"
Mirroring patient's responses and verbalizing the implied	Allows nonthreatening ways for the patient to discuss the situation further and to provide underlying meaning. Mirroring means restating what the patient says almost exactly as the patient says it. Verbalizing means stating what you believe the patient is suggesting by his response. If the patient says, "I have been hurting for 3 days and it is just getting worse and worse. It hasn't quit all day," you might say, "So the pain started about 3 days ago and has been getting worse each day, and today it has not let up at all."
Focusing on patient	Shows the patient that you are really listening to what he is saying. You maintain eye contact (as culturally appropriate), assume a relaxed and open body posture, and use the proper responses.
Encouraging patient to take the lead	Motivates the patient to discuss or describe the situation in his own way. Ask a question such as "Where would you like to begin?"
Encouraging patient to provide additional information	Conveys sincere interest in the patient by continuing to explore topics in more detail when appropriate. You might ask the patient if he has experienced a symptom before or if he associates it with a change in routine. This provides for clarification , or increased understanding of the problem.
Encouraging patient to evaluate his situation	Provides an idea of the patient's point of view about the situation; allows you to determine the patient's knowledge of the situation and possible fears. Ask the patient, "What do you think is going on here?" This will allow you and the patient to use reflection . Reflection is when a thought, an idea, or an opinion is formed as a result of deeper thought, in this case stimulated by a question.
Ineffective Methods	Characteristics
Asking closed-ended questions	Provides little information because closed-ended questions offer the patient little freedom to explain his answers. Closed-ended questions require only yes or no answers.
Asking leading questions	Leading questions suggest a desired response instead of the patient's true response. The patient tends to agree with such statements instead of elaborating on them. An example of a leading question is "You seem to be making progress, don't you agree?" This type of question limits the patient's response.
Challenging patient	The patient may feel you are disagreeing with what he is saying if you ask an emotional or challenging question or use a certain tone of voice. The patient may become defensive, which might block further communication. An example of challenging the patient is "You are not having that much pain from this small wound, are you?"
Probing	Continuing to question a patient after he appears to have finished giving information can make him feel that you are invading his privacy. The patient may become defensive and withhold information.
Agreeing or disagreeing with patient	When you agree or disagree with a patient, it implies that the patient is either "right" or "wrong." This action can block further communication.

use the patient's name in conversation. Avoid interruptions, like taking phone calls and letting people walk in and out of the room. Make sure that you do not use "pet names" for your patients, such as "honey" or "sweetie." Doing so can offend some patients and can be misinterpreted as being insincere.

Dealing with Sensitive Topics with Respect Sometimes you will have to ask patients questions about sensitive topics. Such topics may be related to sexuality, lifestyle, or behaviors that put a person at risk for diseases. You must approach these topics gently so that the patient does not feel threatened by the questioning. You can show respect for the patient's rights and privacy by knowing when to stop. Both verbal and nonverbal clues can guide you in this area. It is also important to be conscious of your body language when dealing with sensitive subjects. You may find yourself exposed to situations that you do not have any experience with, and "shock" may register on your face.

Avoiding Making a Diagnosis or Giving a Diagnostic Opinion Only the physician can make a diagnosis, based on the patient's symptoms and complaints. If the patient asks for your opinion about a diagnosis, explain that the physician should be asked about diagnoses. If pressed, you may need to say you are not able to give opinions about a diagnosis and the physician will answer any questions he or she may have. Never go beyond your scope of practice or job description. Remember, your role as a medical assistant is to observe and report.

Formulating the General Picture Summarize the key points of the interview. Ask the patient whether he or she has questions or other information to add. You will be most successful with the interview process if you remain alert and organized but flexible. Procedure 36-1, at the end of the chapter, demonstrates the proper approach to an interview.

▶ Your Role as an Observer

LO 36.2

During the pre-exam stage of the office visit, you will gather most of your information through verbal and nonverbal communication. The nonverbal communication that occurs during the interview and history taking, however, sometimes reveals more about a patient than the patient's words. Listening attentively and observing the patient closely may help you detect a problem that might otherwise go unnoted.

Anxiety

Anxiety is a common emotional response in patients. Some patients respond with anxiety to a specific fear, such as fear of pain. Others simply feel anxious when they are in an unfamiliar situation. For example, many patients have what is called "white coat syndrome," which is anxiety related to seeing a physician.

To recognize anxiety, you must understand that it varies from mild to severe. A patient with mild anxiety may have a heightened ability to observe and to make connections. A patient with severe anxiety has difficulty focusing on details, feels panicky, and is virtually helpless. Whether a patient has a heightened focus or a lack of focus, it can hinder your ability to get the information and cooperation you need. A patient may use an adaptive (helpful) or a non-adaptive (harmful) coping mechanism to relieve the anxiety. When you observe signs of anxiety in a patient, make every effort to help her use adaptive coping mechanisms such as deep breathing to help her relax and reduce the anxious feelings. You may be able to help by allowing the patient to describe her feelings. If a patient becomes agitated while discussing a physical complaint, you may need to postpone talking about the matter until the patient is calmer. In either situation, give support in nonverbal ways by trying to make the patient as comfortable as possible. Give the patient time to respond and then wait quietly, provide privacy, make eye contact, and communicate at the patient's level of understanding.

Depression

Depression can be difficult to recognize, as some of its symptoms are the same as those of many common illnesses. For example, fatigue and sleep disturbances are symptoms of both depression and hypothyroidism. To complicate matters, many patients with major depression develop great skill in hiding depression or are unaware they are suffering from it. Consequently, many patients—especially the elderly—have undiagnosed depression.

To recognize depression, you must be aware of common symptoms associated with the condition. Classic symptoms of depression are profound sadness and fatigue. In addition, a depressed person may have difficulty falling asleep at night or getting up in the morning. The depressed patient may suffer from loss of appetite, loss of energy, or both.

Depression seems to occur most frequently during late adolescence, in middle age, and after retirement. In late adolescence, depression can be difficult to distinguish from addiction and substance abuse. Depression in middle age is often triggered by life events like financial troubles or death of a family member. It is sometimes confused with midlife crises. And in the elderly, depression is common but often mistaken for senility. If you observe any signs of depression, indicate them in the patient's chart and alert the physician.

As mentioned in the previous paragraph, depression, addiction, and substance abuse in adolescents can be difficult to distinguish, as the signs of substance abuse or addiction can be mistaken for those of depression. The reverse is also true. And sometimes all three conditions exist simultaneously. If you have any clues that point to one of these conditions in an adolescent patient, notify the physician immediately. For symptoms that may be signs of these disorders, see the *Caution: Handle with Care* feature.

Physical and Psychological Abuse

Abuse can involve people from all walks of life and of all ages. Abuse can be physical, psychological, or both. As a medical assistant, you are in a unique position to detect abuse in the patients you see.

CAUTION: HANDLE WITH CARE

Signs of Depression, Substance Abuse, and Addiction in Adolescents

Signs of depression, substance abuse, and addiction are often hard to distinguish in adolescents. Part of the difficulty is that adolescents are particularly skilled at hiding signs of all three disorders.

Various signs may indicate depression in an adolescent. One teenager may lose interest in or be unable to enjoy everyday activities. Another may sleep for long periods and have difficulty getting up in the morning, whereas yet another may sleep very little. Chronic fatigue or aches and pains may signal depression, as may trouble with concentration or school absenteeism. These signs also may indicate substance abuse or addiction.

It is important to know the difference between substance abuse and addiction. **Substance abuse** refers to the use of a substance, even an over-the-counter drug, in a way that is not medically approved. Inappropriate use includes such practices as using diet pills to stay awake and consuming large quantities of cough syrup that contains codeine. It also includes taking larger-than-prescribed doses of a medication. Substance abusers are not necessarily addicts, however.

Addiction refers to a physical or psychological dependence on a substance. Addiction usually involves a pattern of behavior that includes an obsessive or compulsive preoccupation with a

substance and the security of its supply, as well as a high rate of relapse after withdrawal.

As a medical assistant, you should not try to make a diagnosis. Quite likely, an adolescent with one or more of these disorders will be uncooperative and refuse to answer relevant questions. You must be aware, however, of physical signs or behaviors that may be associated with depression, substance abuse, or addiction in an adolescent patient. The following signs or behaviors are important clues that you should report immediately to the doctor.

- The patient complains of altered eating habits or disturbed sleep patterns (either too much or too little sleep).
- The patient's weight has changed drastically (either up or down) since the previous office visit.
- The patient appears lethargic or sullen, or exhibits radical mood changes.
- The patient has slurred speech.
- The patient appears to have illogical thought patterns.
- The patient appears to have needle tracks (anywhere on the body, especially on the arms or legs).
- The patient has pinpoint (highly constricted) pupils.

Although you must not make hasty judgments, you may suspect abuse when a patient speaks in a guarded way. An unlikely explanation for an injury also may be a sign of abuse. There may be no history of the injury, or the history may be suspicious. In either case, the following injuries may be signs of physical abuse:

- Head injuries and skull fractures
- Burns (especially those that appear to be deliberate, such as from a cigarette or an iron)
- Broken bones
- Bruises (especially multiple bruises, those that are clearly in the shape of an object, and those in various stages of healing)

Although a patient can recover physically from abuse, the emotional and psychological scars may last a lifetime. Other signs of physical abuse (including sexual abuse and neglect) and signs of psychological abuse include the following:

- A child's failure to thrive
- Severe dehydration or being underweight
- Delayed medical attention
- Hair loss
- Drug use
- Genital injuries

Women, children, and elderly patients are more likely to be abused. Pay extra attention to these patients when performing the interview. If you suspect abuse, report it to your supervisor

or physician. Prepare a list of local abuse hotline numbers for potential abuse victims.

The Interview and Abuse

Again, because women, children, and the elderly are more likely to be victims of abuse, it is crucial to pay extra attention to them during the interview.

Women According to the Domestic Violence Resource Center, 85% of victims of domestic violence are women, and those ages 20 to 24 are at the greatest risk. Victims stay in abusive relationships for a variety of reasons, including fear of the abuser, threats of suicide by the abuser, financial dependence, lack of housing options, low self-esteem, and isolation. Women who are abused often feel shame. They may make excuses for their abuser or simply will not talk about it. It is important that you not be embarrassed to approach the subject of abuse with the patient. As with any other sensitive topic, you should not worry about embarrassing or insulting the patient by asking sensitive questions. Be kind, supportive, and nonjudgmental while interviewing a woman you suspect may be a victim of abuse. Careful listening and encouragement will build rapport with the patient, making the interview easier for the patient and more productive for you.

Children Children pose a unique situation during the patient interview. For infants and younger children, you will be asking the parent or other caregiver about the child's condition.

However, no matter what the age of the child, you should consider the child first. Communicate with the child, observe the child for nonverbal signs of pain or other problems, and ask questions whenever possible.

Remember, children are often the targets of violence, much of which occurs in the home. In addition to being physically, emotionally, or sexually abused, children can be abused by being neglected. In addition to watching for physical signs of abuse during the interview, watch for any problems in the relationship between the child and the caregiver. If you suspect a problem, report it to the physician.

The Elderly Physical and mental disabilities can make elderly people dependent on a caregiver. So elderly patients may or may not be able to communicate with you verbally during the patient interview. You may need to speak with their caregiver. However, always observe elderly patients for nonverbal signs of problems, such as grimacing, foul odors, or bruising, even if they cannot speak to you verbally. The caregiver may perceive the patient as a burden and abuse can occur. Disabilities may make the elderly person defenseless against abuse. If you suspect a problem, report it to the physician.

Drug and Alcohol Abuse

Substance abuse and addiction to drugs or alcohol are serious social problems. Individuals often use drugs or alcohol

as a non-adaptive coping mechanism to relieve anxiety or emotional pain. Symptoms of substance abuse or addiction differ from drug to drug, as indicated in Table 36-2. Addiction, however, typically causes a gradual decline in the quality of someone's work or relationships. The patient may behave erratically, have frequent mood changes, suffer from loss of appetite, and be constantly tired.

Someone who is abusing alcohol may have no apparent signs or symptoms at first. As time goes on, however, that person may suffer from blackouts (failure to remember what happened while drinking) or may become secretive and guilty about drinking and deny that there is a problem. She may suffer from bruises she does not remember getting, trembling hands, or chronic stomach problems. Even though the patient may feel she does not have a substance abuse or addiction problem, healthcare team members may recognize a problem. When this occurs, their job is to try to persuade the patient to seek help.

Documenting Patient Information LO 36.3

Whenever you interview a patient, keep in mind that the patient chart is a legal document. The chart can be used as evidence in a court of law, so you must meet certain guidelines when recording data.

TABLE 36-2 Symptoms Associated with Commonly Abused Drugs

Drug Names/Type	Trade or Other Name	Symptoms, Effects
Amphetamines/stimulants	Benzedrine, Dexedrine®, methamphetamine, beans, black beauty, speed, uppers, uppies	Altered mental status, from confusion to paranoia; hyperactivity, then exhaustion; insomnia; loss of appetite
Anabolic steroids	Anadrol®, Depo®-testosterone, roids, juice	Irritability, aggression, nervousness, male-pattern baldness
Barbiturates/sedatives	Amobarbital, phenobarbital, Butisol®, secobarbital, yellow jackets, red birds	Slowed thinking, slowed reflexes, slowed respiration, loss of anxiety
Benzodiazepines/sedatives	Ativan®, diazepam, Librium®, Valium®, downers, candy	Poor coordination, drowsiness, increased self-confidence
Cocaine/stimulant	Coke, snow, crack	Alternating euphoria and apprehension, intense craving for more of the drug
Ecstasy/psychoactive	Adam, XTC, MDMA	Confusion, depression, anxiety, paranoia, increased heart rate and blood pressure
GHB/depressants	G, liquid ecstasy, Georgia homeboy	Slow pulse and breathing, lowered blood pressure, drowsiness, poor concentration
Heroin	Big H, black tar, dope, nanoo, nickel deck, smack	Track marks, slowed or slurred speech, vomiting
Inhalants	Solvents: paint thinner Gases: aerosol, butane, or propane	Stimulation, intoxication, hearing loss, arm or leg spasms
LSD (lysergic acid diethylamine)/hallucinogen	Acid, battery acid, microdot	Heightened sense of awareness, grandiose hallucinations, mystical experiences, flashbacks
Marijuana/cannabinoids/hashish	Pot, grass, joints, reefer, weed, chronic, Mary Jane, hash, boom	Altered thought processes, distorted sense of time and self, impaired short-term memory
Opium, morphine, codeine/opiate narcotics	Monkey, white stuff	Decreased level of consciousness, detachment, drowsiness, impaired judgment
PCP (phencyclidine)/hallucinogen	Angel dust, angel mist, hog, rocket fuel, DOA, peace pill	Decreased awareness of surroundings, hallucinations, poor perception of time and distance, possible overdose and death

The Six Cs of Charting

To help ensure that you record patient data accurately, you must follow the six Cs of charting. These guidelines are as follows:

1. *Client's words* must be recorded exactly. The doctor may uncover clues to use in diagnosing the patient's condition. Place quotation marks to indicate what the patient said.
2. *Clarity* is essential when you describe the patient's condition. You must use medical terminology and precise descriptions.
3. *Completeness* is required on all the forms used in the patient record.
4. *Conciseness* can save time and space when you are recording information.
5. *Chronological order* and dates on all entries in patient records are critical in the documentation of patient care. This information also can be used for legal questions regarding medical services. Most charts are arranged with the most recent information on top. This type of charting is known as *reverse chronological order*.
6. *Confidentiality* is essential to protect the patient's privacy. You cannot discuss a patient's records, forward them to

another office, fax them, or show them to anyone except the doctor unless the patient gives you written permission to do so. The only exception is when the records must be sent to ensure continuity of care of the patient and the patient is unable to grant permission.

Contents of Patient Charts

In most medical offices, patient records are electronic. Whether they are electronic or paper, all records must contain the following standard information:

- The patient registration form contains general information, including the date of the patient's current visit, and generally lists the patient's age, address, medical insurance, occupation, education, racial or ethnic background, marital status, number of children, and nearest relative. There is a section that allows the patient to indicate his or her preference about telephone contact, such as leaving messages, or relaying information to designated family members or friends. Some medical offices also use e-mail to communicate with patients. Make sure the patient understands the privacy information section and chooses the appropriate action.

The screenshot displays the Practice Fusion EHR interface for a patient named Nancy Evans. The main window shows the patient's profile with tabs for Summary, Timeline, and Profile. A sidebar on the left contains navigation icons for Home, Schedule, Tasks, Charts, Messages, and Reports. The main content area is divided into sections for Environmental allergies, Medications (with a table showing M-Vit Oral Tablet), Social history, Smoking status, Social history (free text), Past medical history, Major events, Ongoing medical problems, and Allergies (free text). A modal window titled 'Past medical history > Record past medical history' is open on the right, containing fields for MAJOR EVENTS (Gravida 3 Para 4, Menopause 20XX), ONGOING MEDICAL PROBLEMS (Memory loss; poor long and short term memory), ALLERGIES (FREE TEXT) (Amoxicillin), FAMILY HEALTH HISTORY (Mother died with Alzheimer's disease at age 65, Aunt died of Alzheimer's disease at age 68), PREVENTIVE CARE (Annual exams, Pap and Pelvic exam 20XX, Colonoscopy 20XX), SOCIAL HISTORY (Brings husband to appointments; he confirms that her memory issues have been growing more severe.), NUTRITION HISTORY (N/A), and DEVELOPMENTAL HISTORY (N/A). The modal window has 'Cancel' and 'Done' buttons at the bottom.

FIGURE 36-1 Medical history forms in an electronic health record, like this one from Practice Fusion®, allow you to select, enter, or delete items based upon your patient interview.

© Practice Fusion®

- Patient medical history usually includes the chief complaint, history of the present illness, past medical history (including medical treatment, surgeries, known allergies, and current medications), family history, and social and occupational history (including diet, exercise, smoking, and use of alcohol or drugs). This section also may be used to record the results of a general physical exam. See Figure 36-1 for one example.
- Test results include those performed in the office and those received from other physicians, hospitals, or independent laboratories. Physicians may have tests run on a patient's blood, urine, or tissue samples to aid in their diagnoses. Figure 36-2 shows examples of laboratory reports of a panel of chemical tests on blood performed by an outside laboratory.
- Records from other physicians or hospitals are accompanied by a copy of the patient's written authorization to release the records.
- The physician's diagnosis and treatment plan are specific and detailed.
- Operative reports include a record of all procedures, surgeries, follow-up care, and additional notes the physician makes

regarding the patient's case. Continuation forms can be used for additional information. Some medical offices also keep a separate log of telephone calls to and from the patient.

- Informed consent forms verify that the patient has understood the treatment offered and the possible outcomes or side effects of it. The patient signs the consent form but may withdraw consent if she decides to change or discontinue treatment.
- A discharge summary form is used when a patient is hospitalized. This form includes information that summarizes the reason the patient entered the hospital; tests, procedures, or operations performed in the hospital; medications administered; and the disposition, or outcome, of the case.
- Correspondence with or about the patient is marked or stamped with the date the physician's office received the document.

When recording information in the patient chart, be sure to date and initial every entry. This documentation makes it easy to tell which items you entered into the chart and which items others entered. The physician usually initials reports before they are filed to prove that she saw them.

The screenshot shows a software window titled "Lab Test Res..." with a tab labeled "LAB TEST RESULTS". The interface includes a toolbar with various icons for navigation and actions. Below the toolbar, there are two tabs: "Main Info" and "Extra Info". The "Main Info" tab is active, displaying the following fields:

- ID: TEST001
- Test type: COMPLETE BLOOD COUNT
- Date of the Analysis: 5/4/20XX
- Patient Name: Smith, Peter
- Pathologist: Henderson, John
- Date requested: 5/3/20XX
- Physician: Buckwalter, Paul F.

Below these fields is a section titled "Lab Test Criteria" which contains a table with the following data:

W	E	Analyte	Result	Lower Limit	Upper Limit	Units	Remarks
☐	☐	RBC	5.3	4.7	6.1	(males) million cells/mcL	
☐	☐	Hb	15.2	13.8	17.2	(males)gm/dL	
☐	☐	HCT	45.6	40.7	50.3	(males)%	
☐	☐	MCV	82	80	95	femtoliter	
☐	☐	MCH	29	27	31	pg/cell	
☐	☐	MCHC	33	32	36	gm/dL	
☐	☐	Platelets	289,000	150,000	400,000	Platelets/mcL	
☐	☐	WBC	9,600	4,500	10,000	cells/mcL	
☐	☐	Neutrophils	57	40	60	%	
☐	☐	Lymphocytes	32	20	40	%	
☐	☐	Monocytes	7	2	8	%	
☐	☐	Eosinophils	3	1	4	%	
☐	☐	Basophils	1	0.5	1	%	

At the bottom of the window, there is a "Lab Report" button and a status bar showing "Waiting request:0 received-0 sent" and the email address "lab@BWWassociates".

FIGURE 36-2 Laboratory reports (b) Laboratory results paper reports also include normal ranges. All laboratory reports provide valuable information about patients' health.

Methods of Charting

Various methods of charting are used on the medical record. Most methods are based on a series of steps to document the information. These steps are referred to as the SOAP method of documentation (Figure 36-3). Understanding the parts of SOAP will help you document information in a logical manner.

1. *Subjective data.* You obtain **subjective data** from conversation with the patient or an attending family member. Subjective data include thoughts, feelings, and perceptions, including the chief complaint. Such data are based on the patient's interpretation and opinion. They are not measurable by an outside observer; however, you should remember that they are real to the patient. An example of subjective

OUTLINE FORMAT PROGRESS NOTES

Patient Name Chen Cindy M. Date of Birth 07/15/XX Chart # H234
 Last First Middle

Prob. No. or Letter	Date	Subjective	Objective	Assess	Plans
	6/16/XX	<i>Patient complaining of pain in lower right quadrant. Has been running fever of between 100.5° F and 101.3° F since Sunday morning. Has queasy feeling in stomach and has been unable to eat since yesterday morning.</i>			
		<i>BP 125/75. Temperature 101.2° F. Abdominal exam revealed rebound tenderness and distension in lower right quadrant.</i>			
		<i>Appendicitis</i>			
		<i>1. Admit to hospital</i>			
		<i>2. Surgically remove appendix.</i>

PROGRESS NOTES

FIGURE 36-3 When you use the SOAP approach to documenting patient information, start each progress note at the appropriate shaded column to create an outline form. Write through the intervening columns to the right margin of the page. Reprinted with permission from Bibbero Systems, Inc., An InHealth Company, Petaluma, CA (800) 242-2376, www.bibbero.com.

information is the patient's statement about his or her chief complaint: "I have an itchy, red rash on my left hand that I noticed 3 days ago." The patient states that the rash is itchy; since itchiness cannot be observed or measured by the physician, it is considered subjective. The chief complaint should always be recorded in the patient's own words.

2. **Objective data.** **Objective data** are readily apparent and measurable, such as vital signs, test results, and the physician's exam. An example of objective data is the examination of the rash by the physician.
3. **Assessment.** Assessment is the physician's diagnosis or impression of the patient's problem.
4. **Plan of action.** Options for treatment, the type of treatment chosen, medications, tests, consultations, patient education, and follow-up are included in a plan of action. The plan of action may include an order for injection or other treatment that you as the medical assistant will need to perform.

The following are three common methods for maintaining notes on a patient chart:

1. **Conventional or source-oriented medical records (SOMR).** Information is arranged according to who supplied the data or the source. This could be the patient, the

doctor, a specialist, or someone else. The medical form may have a space for patient remarks followed by a section for the doctor's comment.

2. **Problem-oriented medical records (POMR).** This method is used more extensively by large clinics or practices that may have more than one physician who may see the same patient. POMR includes a problem list that is dated, and numbers are assigned to each patient condition or problem. At the patient's initial visit, conditions or problems are identified by a number throughout the record until the problem is resolved. The POMR has four components:
 - **Database.** This includes the patient's medical history, diagnostic and laboratory results, and physical exam reports. This is the foundation of the problem-oriented medical record.
 - **Problem list.** Each patient condition or problem is listed individually, assigned a number, and dated.
 - **Diagnostic and treatment plan.** Laboratory and other diagnostic tests are completed and the physician's treatment plan for the condition is documented.
 - **Progress notes.** The physician enters notes on every condition or problem recorded on the problem list. Progress notes are entered chronologically and include

TABLE 36-3 Common Medical Abbreviations

Abortion	Ab	Headache	HA

Follow-up	F/U	Years old	Y/O
Fracture	FX	Within normal limits	WNL
Growth and development	G & D		

the chief complaint, problems, conditions, treatments, and responses to treatment.

3. Computerized medical records. This method uses a combination of SOMR and POMR but provides accessibility by the physician or other healthcare workers at any time from a computer terminal. This accessibility enhances the patient's continuity of care between departments and specialty physicians in other practices because everyone is looking at the same record.

Common Chart Terminology and Abbreviations

Most of the information that you collect verbally from a patient will be documented in the patient's medical record. Table 36-3 lists some of the most common abbreviations used in the medical chart. Abbreviations used must be accepted by the facility where you are employed as well as The Joint Commission (TJC).

The Joint Commission (TJC) and the Institute for Safe Medication Practice (ISMP) are two healthcare organizations whose mission includes promotion of patient safety. These organizations have identified frequently misinterpreted abbreviations, acronyms, and symbols that have contributed to harmful medical errors. TJC, in 2005, published the *Official "Do Not Use" List*, a standardized list of abbreviations, acronyms, and symbols that are not to be used. See Table 36-4. The ISMP publishes the more comprehensive *ISMP's List of Error-Prone Abbreviations, Symbols, and Dose Designations*,

which is updated periodically. This list includes all of the abbreviations on TJC's "Do Not Use" list, denoting them with a double asterisk (**). It is found at <http://www.ismp.org/tools/abbreviations/>. Although you may see some of these on preprinted order sheets, *do not use* the error-prone abbreviations when charting.

Recording the Patient's Medical History

LO 36.4

A patient's medical history includes pertinent information about the patient and the patient's family. Age, previous illnesses, surgical history, allergies, medication history, and family medical history are key items.

When recording a patient history, you must do more than just fill out the form (Figure 36-4). You must review the pieces of information, organize them, determine their importance, and document the facts. When you write your first histories, you may find it to be a lengthy process. When you become more experienced, however, you will be able to write histories more quickly. Whenever you write information on the chart, you must consider its completeness and accuracy. First determine the chief complaint, or the main reason for the patient visit. For example, the patient may have a rash or pain. Then ask more questions. A good interview technique is the "PQRST" interview technique. It will help you remember the types of questions that are appropriate for the condition. Each letter stands for a word that will remind you to ask more specific questions about the chief complaint or problem the patient is having:

- P: Provoke or Palliative
- Q: Quality or Quantity
- R: Region or Radiation
- S: Severity Scale
- T: Timing

See Table 36-5 for questions and charting examples using the PQRST interview technique.

You will need to chart other information prior to the physician visit. Figure 36-5b shows a form used by the medical assistant and the licensed practitioner when seeing a patient. When keying information in an electronic record, it is just as important to correctly type the information into the record. Pay special attention to spelling when entering data into the chart or electronic record. If you do not know how to spell a word, look it up. Use only TJC-approved and office-recognized abbreviations (see Tables 36-3 and 36-4). Many facilities have a document identifying these abbreviations. Electronic health records often use drop-down menus with common medical information provided. Take care to click the correct box when using drop-down menus. Remember, the chart is a legal document, so special attention to detail is required when charting.

The Progress Note

Many offices use a variation of the progress note for established patients who are seen for routine visits or follow-ups like hypertension, arthritis, or flu (see Figures 36-3 and 36-5).

TABLE 36-4 TJC “Do Not Use” Abbreviations, Acronyms, and Symbols

Abbreviation	Potential Problem	Preferred Term
U (for unit)	Mistaken as zero, four, or cc.	Write “unit.”
IU (for international unit)	Mistaken as IV (intravenous) or 10 (ten).	Write “international unit.”
Q.D., QD, qd, q.d., Q.O.D., QOD, q.o.d, qod (Latin abbreviation for once daily and every other day)	Mistaken for each other. The period after the Q can be mistaken for an “I” and the “O” can be mistaken for “L.”	Write “daily” and “every other day.”
Trailing zero (X.0 mg), lack of leading zero (.X mg) except when trailing zero is used to indicate a level of precision when reporting a lab value	Decimal point is missed.	Never write a zero by itself after a decimal point (X mg), and always use a zero before a decimal point (0.X mg) when writing medication documentation.
MS MSO ₄ MgSO ₄	Confused for one another. Can mean morphine sulfate or magnesium sulfate.	Write “morphine sulfate” or “magnesium sulfate.”
Other Abbreviations, Acronyms, and Symbols to Avoid		
µg (for microgram)	Mistaken for mg (milligrams), resulting in one-thousand-fold dosing overdose.	Write “mcg.”
c.c. (for cubic centimeter)	Mistaken for U (units) when poorly written.	Write “mL” for milliliters.
> (greater than) < (less than)	Misinterpreted as the number “7” or the letter “L”; confused for one another.	Write “greater than” and “less than.”
Abbreviations for drug names	Misinterpreted due to similar abbreviations for multiple drugs.	Write drug names in full.
Apothecary units	Unfamiliar to many practitioners. Confused with metric units.	Use metric units.
@	Mistaken for the number “2” (two).	Write “at.”
H.S. (for half-strength or Latin abbreviation for bedtime)	Mistaken for either half-strength or hour of sleep (at bedtime). qH.S. mistaken for every hour. All can result in a dosing error.	Write out “half-strength” or “at bedtime.”
T.I.W. (for three times a week)	Mistaken for three times a day or twice weekly, resulting in an overdose.	Write “3 times weekly” or “three times weekly.”
S.C. or S.Q. (for subcutaneous)	Mistaken as SL for sublingual, or “5 every.”	Write “Sub-Q,” “subQ,” or “subcutaneously.”
D/C (for discharge)	Interpreted as discontinue whatever medications follow (typically discharge meds).	Write “discharge.”
A.S., A.D., A.U. (Latin abbreviation for left, right, or both ears) O.S., O.D., O.U. (Latin abbreviation for left, right, or both eyes)	Mistaken for each other (such as AS for OS, AD for OD, AU for OU, etc.).	Write “left ear,” “right ear,” or “both ears”; “left eye,” “right eye,” or “both eyes.”

The medical history form is primarily used for new patients the physician is seeing for the first time. The following are some important guidelines to consider when using a progress note:

- It must be arranged in reverse chronological order.
- Every entry must be initialed and signed by the person making the entry. Typically, the first initial, last name, and credentials are used—for example, K. Haddix, RMA (AMT).
- Entries most commonly made on progress notes include documentation for prescription refills, follow-up visits, telephone conversations with patients, appointment cancellations or no shows, and referrals and consultation efforts made by the office for the patient.

- The patient name must be recorded on every progress note along with any other identifying information such as birth date or chart number.
- All entries must be dated. All entries typically include the time and must always include the date.

Procedure 36-2, at the end of this chapter, will guide you in how to use a progress note.

Polypharmacy

Many patients will take a variety of medications to treat several conditions, such as hypertension, elevated cholesterol, and diabetes. Some patients take several medications for the same condition, with each one treating a different aspect of the condition. The chapters *Principles of Pharmacology* and

Name _____ Today's Date _____
Age _____ Birthdate _____ Date of last physical examination _____
What is your reason for visit? _____

FIGURE 36-4 The health history form must be complete and accurate. The patient should start the form and the medical assistant should check and complete it.

TABLE 36-5 Example Questions When Using the PQRST Interview Technique

PQRST Interview Technique	Chief Complaint: <i>Itching/Rash Under Arms</i>	Chief Complaint: <i>Pain in the Left Shoulder</i>	Chief Complaint: <i>Persistent Cough</i>
P: Provoke or Palliative	- What causes the itching to occur? - Does anything make the itching go away?	- When did you first notice the pain? - Is there anything you do that reduces the pain?	- When is the cough worse? Morning? Night? - Is there anything that relieves the cough? Aggravates it?
Q: Quality or Quantity	- How severe is the rash/itching? - How often does the itching occur?	- Can you describe the pain: dull, aching, burning, or sharp? - When does the pain occur?	- Is the cough productive or nonproductive? - Are you coughing anything up? If so, does it have any color? - Do you have pain when you cough?
R: Region or Radiation	Where is the itching/rash?	- Where do you feel the pain? - Does the pain move from one location to another?	- Is the pain on one side or both? - Does the pain radiate?
S: Severity Scale	Is the rash/itching interfering with your daily life?	- Is the area red or tender to the touch? - Is there any swelling? - Rate the pain on a scale of 1 to 10, with 10 being the worst. (See Figure 36-6.)	- Rate the pain on a scale of 1 to 10, with 10 being the worst. - Does the cough disturb your sleep?
T: Timing	When did you first notice the rash/itching?	- How long have you had the pain? - Is the pain intermittent or continuous? - How long does the pain last?	- Does the cough come in bouts or fits or is it continuous? - How long have you had the cough?

Medication Administration provide detailed information regarding various medications. During the patient interview, it is important to document medications the patient is currently taking. The patient will often see several physicians or specialists, and it is important for your office to be up to date on the treatments a patient is receiving. This reduces the likelihood of polypharmacy or unnecessarily repeating medical tests.

Some offices may use a medication flowsheet for the physicians to record patient medication histories. In some cases, the medical assistant gathers the information for the current medication flowsheet (see Figure 36-7). A helpful hint for organizing this task is to develop a form or card for the patient to use (if the office does not already have a form) and gather the initial medication history. Then instruct the patient to use the list and to have it updated by the other physicians whom he or she sees. A drug reference guide or the Internet will assist you with the spelling of medications.

The Health History Form

The medical office usually has a standard medical history form that is used for all patients. The specific arrangement and wording of items on this form, however, may vary from office to office. The following sections contain brief descriptions of each of the parts of this form. Procedure 36-3, at the end of this chapter, will assist in your practice of obtaining medical histories.

Personal Data This information is obtained from the administrative sheet and includes the patient's name, birth date, and other basic data.

Chief Complaint Abbreviated as CC, the chief complaint is the reason the patient came to visit the practitioner. It should be short and specific and should cover subjective and/or objective data stated by the patient.

History of Present Illness This history includes detailed information about the chief complaint, including when the problem started and what the patient has done to treat the problem (including any medications taken). For example, a chief complaint might be "sore throat" and the history of the present illness would include when the sore throat started (such as 3 days ago), how severe the pain is on a scale of 1 to 10 (such as pain scale rating of 6 out of 10), and what treatments have been used (such as throat lozenges and four to six aspirin daily).

Past Medical History The past medical history includes any and all health problems both present and past, including major illnesses and surgery. The past medical history also includes important information about medications and allergies. It should list any medications taken by the patient, including their dosages and the reasons for taking them. Over-the-counter and herbal medications should be listed as well. Known or suspected allergies to medications or other substances should be listed and clearly visible. Some facilities use a red sticker or other means on charts to identify allergies immediately. Most electronic health record programs

automatically run drug allergy and drug-drug interaction checks. If you are entering medication data into an EHR program that does not have this feature, make sure you flag patient drug allergies according to office policy.

Family History This section includes information about the health of the patient's family members. Many times, the family history can help lead a practitioner to the cause of a current medical problem. Obtain specific information about family members' current ages and medical conditions or, if deceased, their age at death and the cause. Ask open-ended

questions about the siblings, parents, and grandparents. Because the death of a parent or sibling or the limited knowledge of an adopted child can be difficult to discuss, use great care and sensitivity when asking these questions.

Social and Occupational History Information like marital status, sexual behaviors and orientation, occupations, hobbies, and the use of chemical substances helps determine a patient's risk for disease. Patients should be asked about their use of alcohol, tobacco, recreational drugs, or other chemical substances. Be aware that patients may feel uncomfortable

FIGURE 36-6 Assessing a patient's pain, considered the fifth vital sign, is part of the interview and history-taking process. A chart similar to this is used to make the process easier for the patient and the medical assistant.

or may refuse to provide certain information. Depending on the circumstances, you may ask the question later in the interview. For example, an adolescent child may not want to answer questions about his sexual behaviors in front of his parents. Occupational information regarding the patient's level of stress, exposure to hazardous substances, and heavy lifting also may be included here.

Review of Systems Some of this information may be started by the patient but is completed by the practitioner. This systematic review of each of the body systems includes questions and an exam by the practitioner. The information is obtained in an orderly fashion but may vary depending on the physician or practitioner.

PROCEDURE 36-1 Using Critical Thinking Skills During an Interview

WORK // DOC

Procedure Goal: To be able to use verbal and nonverbal clues and critical thinking skills to optimize the process of obtaining data for the patient's chart

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Progress note, patient chart or electronic health record, pen (if using a paper record)

Method:

Example 1: Getting at an Underlying Meaning

1. You are interviewing a female patient with Type 2 diabetes who has recently started insulin injections. She is in the office for a follow-up visit.
2. Use open-ended questions such as "How are you managing your diabetes?"

RATIONALE: *Open-ended questioning allows the patient to explain the situation in her own words and often provides more information than closed-ended questioning.*

3. The patient states that she "just can't get used to the whole idea of injections."
4. To encourage her to verbalize her concerns more clearly, you can mirror her response or restate her comments in your own words. For example, you might say, "You seem to be having some difficulty giving yourself injections."

FIGURE Procedure 36-1 Example 2 Step 4 Do not try to handle by yourself a patient who may become violent. Ask for help from other staff members.

© McGraw-Hill Education

RATIONALE: *This response should encourage her to verbalize the specific area in which she is having problems such as loading the syringe, injecting herself, finding the time for the injections, and so on.*

5. Verbalize the implied, which means that you state what you think the patient is suggesting by her response.

RATIONALE: *Restating her response ensures you have understood.*

6. After you determine the specific problem, you will be able to address it in the interview or note it in the patient's chart for the doctor's attention.

Example 2: Dealing with a Potentially Violent Patient

1. You are interviewing a 60-year-old male patient who is new to the office. He appears agitated. You ask his reason for seeing the doctor today.
2. The patient explains that he does not want to talk to "some assistant" about his problem. He just wants to see the doctor.
3. You say that you respect his wish not to discuss his symptoms but explain that you need to ask him a few questions so that the doctor can be prepared to provide the proper medical care. Ask questions that help the patient reflect on his or her situation.

RATIONALE: *The patient has the right to refuse to answer a question, even if it is a reasonable one.*

4. The patient begins to yell at you, saying he wants to see the doctor and does not "want to answer stupid questions."

FIGURE Procedure 36-1 Example 3 Step 2 Gather any symptom information you can from the child. Then ask the parent or caregiver similar questions.

© McGraw-Hill Education

5. The fact that the patient appears agitated and begins to raise his voice in anger should be a warning to you that he may become violent. It would be best not to handle this patient by yourself.
6. If you are alone with the patient, leave the room and request assistance from another staff member.

Example 3: Gathering Symptom Information About a Child

1. A parent brings a 5-year-old boy to the office because the child is complaining about stomach pain.
2. To gather the pertinent symptom information, ask the child various types of questions.

RATIONALE: *Talking to the child first allows him to feel that his view of the problem is important.*

- a. Can he tell you about the pain?

RATIONALE: *Open-ended questioning allows him to tell you about his problem in his own words.*

- b. Can he tell you exactly where it hurts?
 - c. Is there anything else that hurts?
3. To clarify the child's answers, ask the parent to answer similar questions.
 4. You should then ask the parent additional questions. Begin with an open-ended question, as above. Follow up with specific questions such as these:
 - a. How long has he had the pain?
 - b. Is the pain related to any specific event (like going to school)?
 5. Ask the child to confirm the parent's answers. He may be able to provide additional information at this time.

PROCEDURE 36-2 Using a Progress Note

WORK // DOC

Procedure Goal: To accurately record a chief complaint on a progress note

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Progress note, patient chart or electronic health record, pen (if using a paper record)

Method:

1. Wash your hands.
2. Review the patient's chart notes from the patient's previous office visit. Verify that all results for any previously ordered laboratory work or diagnostics are in the chart.

RATIONALE: *Ensures that all reports have been reviewed by the physician*

3. Greet the patient and escort her to a private exam room.
4. Introduce yourself and ask the patient her name.
5. Using open-ended questions, find out why the patient is seeking medical care today.

RATIONALE: *Asking open-ended questions like "What is the reason for your visit today?" and "How long have you been feeling this way?" will encourage the patient to provide more details.*

6. Accurately document the chief complaint on the progress note. Document vital signs. Initial or sign the chart entry according to office policy.

BWW PROGRESS NOTE

7. File the progress note in chronological order within the patient's chart if the record is a paper record. Refer to Progress Note.

RATIONALE: *This ensures that the most current patient information is reviewed by the physician and the medical staff.*

8. Thank the patient and offer to answer any questions she may have. Explain that the physician will come in soon to examine her.
9. Wash your hands.

PROCEDURE 36-3 Obtaining a Medical History

WORK // DOC

Procedure Goal: To obtain a complete medical history with accuracy and professionalism

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Medical history form, physical examination form, patient chart, pen or electronic medical record

Method:

1. Wash your hands.

2. Assemble the necessary materials. Review the medical history form and plan your interview.
RATIONALE: *This saves time and improves the effectiveness of the visit; plus, it will assist in determining the appropriate questions to ask.*
3. Invite the patient to a private exam room and correctly identify the patient by introducing yourself and asking his or her name and date of birth.
4. Explain the medical history form while maintaining eye contact. Make the patient feel at ease.
5. Using language that the patient can understand, ask appropriate, open-ended questions related to the

medical history form. Listen actively to the patient's response using reflection, restatement, and clarification.

6. Accurately document the patient's responses.
7. Thank the patient for his or her participation in the interview. Offer to answer any questions.
8. Sign or initial the medical history form and file it in the patient's chart.
9. Inform the physician that you are finished with the medical history according to the physician's office policy.
10. Wash your hands.

SUMMARY OF LEARNING OUTCOMES	
LEARNING OUTCOMES	KEY POINTS
36.1 Identify the skills necessary to conduct a patient interview.	The skills necessary to conduct an interview include effective listening, awareness of nonverbal cues, use of a broad knowledge base, and the ability to summarize a general picture.
36.2 Recognize the signs of anxiety; depression; and physical, mental, or substance abuse.	Anxiety can range from a heightened ability to observe to a difficulty in being able to focus. Depression can be demonstrated through severe fatigue, sadness, difficulty sleeping, and loss of appetite. Abuse can be physical (such as an injury) or psychological (such as neglect).
36.3 Use the six Cs for writing an accurate patient history.	The six Cs for writing an accurate patient history are client's words, clarity, completeness, conciseness, chronological order, and confidentiality.
36.4 Carry out a patient history using critical thinking skills.	When obtaining a patient history, you can use open-ended questions, active listening, clarification, restatement, reflection, and the PQRST interview technique; review the information obtained; determine the importance; and then document the facts accurately.

CASE STUDY CRITICAL THINKING

© Image Source/Getty Images RF

Recall Peter Smith from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. What diagnosis will the licensed practitioner most likely give this patient?

2. What specific symptoms make you suspect this condition?
3. Mr. Smith complains of not being able to fall asleep. Is this information objective or subjective data?
4. Why do you think a sleep study was ordered?

EXAM PREPARATION QUESTIONS

- (LO 36.3) Which of the following represents objective data?
 - Headache
 - Pain
 - Itching
 - Rash
 - Nausea
- (LO 36.1) Which of the following is an open-ended question?
 - How long have you had the rash under your arm?
 - So, have you had a headache for 3 days on the left side of your head?
 - Can you tell me more about your symptoms?
 - How long does your pain last?
 - Does your left arm hurt?
- (LO 36.1) Which of the following is the most effective question to use during a patient interview?
 - Do you agree that you are getting better when you use the medicine?
 - Have you had a headache every day this week?
 - Do you agree you should not have taken so much medication?
 - What do you think is going on here?
 - You haven't been taking your medicine, have you?
- (LO 36.2) Which type of patient is the *least* likely victim of abuse?
 - A 2-year-old child
 - A 48-year-old male
 - A 78-year-old male
 - A 35-year-old female
 - An 85-year-old female
- (LO 36.3) Which of the following is an accepted abbreviation?
 - HA
 - OU
 - HS
 - ASA
 - AU
- (LO 36.4) In the PQRST interview technique, the "P" stands for
 - Prescription
 - Problem
 - Provoke
 - Plan
 - Prevent
- (LO 36.2) The intentional use of a medication or other substance in a way that is not medically approved is known as
 - Medication error
 - Substance abuse
 - Polypharmacy
 - Addiction
 - Palliation
- (LO 36.3) Which of the following is considered subjective data?
 - Rash
 - Fever
 - Increased pulse rate
 - Headache
 - Hypertension
- (LO 36.1) "You seem to be having trouble taking your medication, don't you agree?" is an example of
 - Asking a leading question
 - Asking an open-ended question
 - Asking a hypothetical question
 - Focusing on the patient
 - Mirroring the patient's response
- (LO 36.4) Asking a patient if his pain moves from one location to another is an example of which part of the PQRST interview technique?
 - P
 - Q
 - R
 - S
 - T

Go to CONNECT to see activities about *Building a Patient's Face Sheet*, *Printing a Patient's Face Sheet*, and *Documenting in a Patient's Progress Note*.

SOFT SKILLS SUCCESS

Mrs. Smithers, an 83-year-old established patient, is in today for follow-up after falling and breaking her arm 2 weeks ago. Her daughter is with her and insists on going back to the exam room. During the patient interview, you notice that each time you ask Mrs. Smithers a question her daughter answers before she is able to. How should you handle this situation?

Go to PRACTICE MEDICAL OFFICE and complete the module Clinical - Interactions.

Vital Signs and Measurements

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Mohammad Nassar	5/17/20XX	Animal dander
	Attending	MRN	Other Information
	Elizabeth H. Williams, MD	423-90-687	Current medication: albuterol 4 mg bid

Mohammad Nassar, a 16-year-old male, comes to the office because he has had several episodes of what he describes as “my heart is beating too fast.” Mohammad has a known history of asthma that is being managed using albuterol. You measure his vital signs and record that his blood pressure is 104/62, his pulse is currently 88 beats per minute, his oral temperature is 99.1°F, and his respirations are 18

© David Sacks/Getty Images

breaths per minute. He is 5'10" tall and weighs 140 lb. When you ask about the episodes he has experienced, he says they often occur in the evening while he is studying for a big exam. He says he drinks coffee in order to stay awake later and is worried about keeping his grades up so that his parents will continue to allow him to play sports.

Keep Mohammad in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 37, you will be able to:

- 37.1** Describe the vital signs.
- 37.2** Identify various methods of taking a patient's temperature.
- 37.3** Describe the process of obtaining pulse and respirations.
- 37.4** Carry out blood pressure measurements.
- 37.5** Summarize orthostatic, or postural, vital signs.
- 37.6** Illustrate various body measurements.

KEY TERMS

- | | |
|----------------------------|-------------------------|
| afebrile | hypotension |
| apnea | orthostatic hypotension |
| auscultated blood pressure | palpatory method |
| body mass index (BMI) | positive tilt test |
| bradycardia | postural hypotension |
| calibrate | rales |
| dyspnea | rhonchi |
| febrile | sphygmomanometer |
| hyperpnea | stethoscope |
| hyperpyrexia | tachycardia |
| hypertension | tachypnea |
| hyperventilation | thermometer |

- I.P.1** Measure and record:
- (a) blood pressure
 - (b) temperature
 - (c) pulse
 - (d) respiration
 - (e) height
 - (f) weight
 - (i) pulse oximetry
- I.P.6** Analyze healthcare results as reported in:
- (a) graphs
 - (b) tables
- II.P.4** Document on a growth chart
- V.P.11** Report relevant information concisely and accurately
- X.P.3** Document patient care accurately in the medical record

- 2. Anatomy and Physiology**
- c. Identify diagnostic and treatment modalities as they relate to each body system
- 4. Medical Law and Ethics**
- f. Comply with federal, state, and local health laws and regulations as they relate to healthcare settings
- 9. Clinical Procedures**
- b. Obtain vital signs, obtain patient history, and formulate chief complaint
 - j. Make adaptations with patients with special needs

► Introduction

Vital signs are one of the most important assessments you can make when preparing the patient to be examined by the practitioner. Temperature, pulse, respirations, and blood pressure give information about how a patient will adjust to changes within the body and in the environment. Changes in the vital signs can indicate an abnormality.

Measurements such as height, weight, and head circumference can indicate physical growth and development, especially in infants and children. These measurements also are used to evaluate health problems such as obesity, and other measurements are completed to evaluate a patient's condition. For example, you may need to measure the size of a wound or bruise or the diameter of an arm or a leg. In all cases, you must be accurate when performing and recording vital signs and body measurements. The practitioner uses your results when making a diagnosis.

► Vital Signs

LO 37.1

As a medical assistant, you will usually take the vital signs before the doctor examines the patient. Vital signs include temperature, pulse, respirations, and blood pressure. Pain assessment, which was discussed in the *Patient Interview and History* chapter, is considered by some practitioners to be the “fifth vital sign.” Pain level is typically evaluated during the patient interview and recorded along with the vital signs. These measurements provide the doctor with information about the patient's overall condition.

In some offices, pre-exam procedures such as vital signs are performed in a general area outside the patient exam

room. In other offices and in most pediatric offices, these measurements are taken in the exam room. In either case, you typically take the measurements before the patient disrobes. Follow the standard procedure used in your office and be sure to follow the HIPAA regulations and provide for the privacy of your results.

Vital signs are usually measured at every office visit. There is a standard range of values for each measurement, as shown in Table 37-1, and each patient has an individual baseline value that is normal for that patient. The difference between a patient's current values and normal values can help the licensed practitioner in making a diagnosis. You must follow closely the guidelines from the Department of Labor's Occupational Safety and Health Administration (OSHA) for taking measurements of vital signs (Table 37-2). These guidelines are intended to prevent transmission of disease to or from the patient. They help protect the patient and you, and they keep the workplace safe.

► Temperature

LO 37.2

When you take a patient's temperature, you will determine whether the patient is **febrile** (has a body temperature above the patient's normal range) or **afebrile** (has a body temperature within the patient's normal range). A fever is usually a sign of inflammation or infection. An exceptionally high fever is known as **hyperpyrexia**. Body temperature is the balance between heat produced by metabolic processes and heat lost from the body; it varies based on numerous factors. These factors include the time of day (usually higher at night due to exercise and food intake), age, gender, physical exercise, emotion, pregnancy, drugs, food, environmental changes, and

TABLE 37-1 Normal Ranges for Vital Signs*

Vital Sign	Age					
	0–1 Year	1–2 Years	2–5 Years	6–12 Years	Greater Than 12 Years	Adult
Temperature						
Oral (°F)	—	—	—	97.4–99.5	97.6–99.6	97.8–99.1
Rectal (°F)	99–100	97.9–100.4	97.9–100.4	97.9–100.4	98.6–100.6	98.8–100.1
Pulse (beats per minute)	100–160	90–150	80–140	70–120	60–100	60–100
Respirations (per minute)	30–60	24–40	22–34	18–30	12–16	12–18
Blood pressure (mmHg)**						
Systolic	80–106	80–106	84–112	91–123	101–136	Less than 120
Diastolic	34–54	34–59	39–70	53–79	59–84	Less than 80

*Normal vital signs vary. Always compare your results with previous results obtained on the patient.

**Classifications for adult blood pressure are shown in Table 37-4.

*Pediatric blood pressure ranges vary greatly based on height percentiles and gender. Always consult the licensed practitioner regarding specific ranges for each patient.

TABLE 37-2 OSHA Guidelines for Taking Measurements of Vital Signs

Situation	OSHA Guidelines
Before and after all patient contact	- Examination area cleaned according to OSHA standards - Aseptic handwashing
Temperature by oral or rectal route	Gloves always worn for rectal route
Contact with patient with lesions	Gloves worn for oral route if contact precautions exist
Contact with patient suspected of having infectious disease	Biohazard bags used for disposal of used thermometer sheaths, otoscope tips, alcohol swabs, dressings, and bandages
In presence of patient suspected of having an airborne infectious disease (particularly sneezing)	- Mask worn - Patient weighed, measured, and examined in room away from staff and other patients - Protective clothing (laboratory coat, gown, or apron) worn - Biohazard bags used as above

metabolism (a slow metabolism, as seen in hypothyroidism, would cause a lower temperature). The body location where the temperature is measured also can affect the result.

Temperature is measured with either an electronic or a disposable **thermometer**. You can take a temperature in one of five locations: mouth (oral), ear (tympanic), rectum (rectal), armpit or axilla (axillary), and temporal artery (temporal). Temperature can be measured in degrees Fahrenheit (°F) or degrees Celsius (°C). Table 37-3 gives equivalent values for these two temperature scales. Normal adult oral temperature is considered to be about 98.6°F or 37.0°C. See the *Points on Practice* box to review formulas and example conversions.

Electronic Digital Thermometers

Electronic digital thermometers are used frequently in medical offices. These thermometers provide a digital readout of the patient's temperature (Figure 37-1). They are accurate, fast, easy to read, and comfortable for the patient. Separate probes and tips are available for oral and rectal use. Most units beep or have another audible indicator to let you know when the temperature has registered and is displayed.

Another type of electronic thermometer is the tympanic thermometer, which is designed for use in the ear. See Figure 37-2. This thermometer measures infrared energy

TABLE 37-3 Fahrenheit and Celsius Equivalents for Temperature

°F	°C	°F	°C	°F	°C	°F	°C
95.0	35.0	98.4	36.9	101.8	38.8	105.2	40.7

98.2	36.8	101.6	38.7	105.0	40.6		

POINTS ON PRACTICE

Math for Measurements

When performing vital signs and measurements, certain basic math conversions may be required. You may need to convert a temperature from Fahrenheit (°F) to Celsius (°C), weight from pounds (lb) to kilograms (kg), or inches to feet and inches. Review the following formulas and examples in preparation for practice.

To convert °C to °F, use this formula:

$$^{\circ}\text{F} = (^{\circ}\text{C} \times 9/5) + 32$$

Example: Convert 37.6°C to °F:

$$^{\circ}\text{F} = (37.6 \times 9/5) + 32$$

$$^{\circ}\text{F} = (338.4/5) + 32$$

$$^{\circ}\text{F} = 67.68 + 32$$

$$^{\circ}\text{F} = 99.68, \text{ rounded to the nearest tenth equals } 99.7$$

To convert °F to °C, use this formula:

$$^{\circ}\text{C} = (^{\circ}\text{F} - 32) \times 5/9$$

Example: Convert 99.6°F to °C:

$$^{\circ}\text{C} = (99.6 - 32) \times 5/9$$

$$^{\circ}\text{C} = 67.6 \times 5/9$$

$$^{\circ}\text{C} = 338/9$$

$$^{\circ}\text{C} = 37.55, \text{ rounded to the nearest tenth equals } 37.6$$

To convert kg to lb, use this formula:

$$\text{lb} = \text{kg} \times 2.205$$

Example: Convert 52.4 kg to lb:

$$\text{lb} = 52.4 \times 2.205$$

$$\text{lb} = 115.542, \text{ rounded to the nearest tenth equals } 115.5$$

To convert lb to kg, use this formula:

$$\text{kg} = \text{lb} \times 0.454$$

Example: Convert 134 lb to kg:

$$\text{kg} = 134 \times 0.454$$

$$\text{kg} = 60.836, \text{ rounded to the nearest tenth equals } 60.8$$

To convert inches to feet and inches:

Divide the number of inches by 12 and carry the remainder. The answer is the number of feet and the remainder indicates the number of inches. For example, $66/12 = 5$ with a remainder of 6, so a person who is 66 inches tall is 5 feet, 6 inches tall.

FIGURE 37-1 An electronic digital thermometer provides a digital readout of the patient's temperature.

© McGraw-Hill Education

emitted from the tympanic membrane (eardrum). This energy is converted into a temperature reading. The tip is covered with a disposable sheath to prevent cross-contamination.

A third type of electronic thermometer is a temporal scanner (Figure 37-3). This thermometer measures the infrared heat of the temporal artery and the ambient temperature (the temperature around the area) at the site where the temperature is taken. These two readings are processed to calculate the body temperature, which is then displayed on the screen.

Disposable Thermometers

Disposable, single-use thermometers are usually made of thin strips of plastic with specially treated dot or strip indicators (Figure 37-4). The indicators change color according to the temperature. This type of thermometer is used for oral and

FIGURE 37-2 The tympanic thermometer measures infrared energy emitted from the tympanic membrane. The result, converted to body temperature, is displayed within seconds of insertion of the shielded tip into the ear.

axillary or skin temperature measurements, particularly in children. Although not as accurate, disposable thermometers are useful for patients in their homes.

Taking Temperatures

Using the proper instrument and technique provides the most accurate temperature readings and prevents the spread of infection. All temperature measurements should be recorded to the nearest one-tenth of a degree. The procedure for taking temperatures is described in Procedure 37-1 at the end of this chapter.

Measuring Oral Temperatures To take an oral temperature, make sure the patient is able to hold the thermometer in the mouth. The patient also must be able to breathe through the nose. Place the thermometer under the tongue in either pocket just off-center in the lower jaw (Figure 37-5). The patient should hold the thermometer with lips closed. Wait at least 15 minutes after a patient has been eating, drinking, or smoking before taking an oral temperature; otherwise, you may obtain an inaccurate result.

Measuring Tympanic Temperatures Proper technique must be used when measuring a tympanic temperature. These thermometers are easy to use, but you must follow manufacturers' instructions precisely. First, remove the thermometer from its recharging cradle and then wait for the indicator light to show that the unit is ready. Attach a disposable sheath and place the thermometer in the opening of the ear so that the fit is snug. To make sure you have a tight fit and the thermometer is pointing at the eardrum, pull the ear up and back for adults; pull the ear down and back for children. Pull the ear correctly for each age group to ensure that the thermometer is aiming directly at the eardrum. Press the button and the result will be displayed within seconds. Be certain to press the correct button to read the temperature. Another button on the thermometer releases the sheath. You do not want to release the sheath into the patient's ear. See the *Caution: Handle with Care* box for problems that can occur with tympanic thermometers.

FIGURE 37-5 When taking an oral temperature, place the thermometer under the tongue to the side of the mouth, as shown here.

Measuring Rectal Temperatures Rectal temperatures are usually 1°F higher than oral temperatures and are considered the most accurate measurement of body temperature. Temperatures are sometimes measured rectally in infants and in adults in whom an oral temperature cannot be taken. Gloves are always worn and the patient is placed on his or her side. The left side is the preferred position because the rectum is angled in this direction. This position promotes comfort and prevents accidental puncture of the rectal wall. The tip of the thermometer should be inserted slowly and gently until it is covered or until you feel resistance, at approximately 1 inch for adults and ½ inch for infants and small children. For safety, always hold the thermometer in place while taking the temperature.

Measuring Axillary Temperatures To take an axillary temperature, first have the patient sit or lie down. Place the tip of the thermometer in the middle of the axilla (armpit), with the shaft facing forward. The patient's upper arm should be pressed against his side and his lower arm should be crossed over the stomach to hold the thermometer in place. Make sure the tip of the thermometer touches skin on all sides of the probe. The axillary temperature is 0.5 to 1 degree lower than the oral temperature and 2 degrees lower than the rectal temperature. Therefore, if the patient's axillary temperature is 99 degrees or higher, verify the patient's temperature using another method, because the patient may have a fever. Be sure to note the location of temperature measurement on the patient's chart.

CAUTION: HANDLE WITH CARE

Tympanic Thermometers: Where Problems Can Occur

The technique for taking a tympanic temperature may vary slightly, depending on which brand of thermometer you use. Most units have an indicator to let you know when the thermometer is ready for use. Some units require taking the temperature within a certain period after removing the thermometer from its charging base. Read the manufacturer's instructions for specific information.

There can be problems if the outer opening of the ear is not sealed completely when the probe is placed at the ear canal or the thermometer is not aimed at the eardrum. You may need to tug gently on the ear to position the thermometer properly and aim it at the eardrum. For adults pull the ear up and back; for children pull the ear down and back.

If the thermometer has been charging for several hours before use, the initial reading may be inaccurately high. So some experts believe you should take two measurements on the first patient after charging the unit and record only the second reading.

Even with good technique, problems can sometimes occur. For example, excessive or impacted cerumen (earwax) or otitis media (ear infection) may prevent an accurate reading. If you obtain a reading that does not appear to match the patient's general condition, repeat the temperature measurement to be sure. It may be necessary to use a different method. Additionally, if a patient has otitis media, the tympanic temperature reading may be higher than the actual body temperature.

Measuring Temporal Temperatures The temporal scanner is a quick, noninvasive procedure for taking temperatures. You gently stroke the thermometer across the forehead, crossing over the temporal artery (on the side of the forehead at the temple). An infrared scanner measures the difference in the temperature of the forehead and that of the temporal artery and then electronically calculates the patient's body temperature. As with all electronic devices, check the manufacturer's instructions before using.

► Pulse and Respiration

LO 37.3

Pulse and respiration are related because the circulatory and respiratory systems work together. Pulse is measured as the number of times the heart beats in 1 minute. Respiration is the number of times a patient breathes in 1 minute. One breath, or respiration, equals one inhalation and one exhalation. Usually, if either the pulse or respiration rate is high or low, the other is also. The usual ratio of the pulse rate to the respiration rate is about 4:1 (for example, a pulse of 80 and a respiration of 20). In general, the younger the patient, the higher the normal pulse and respiration rate. Additionally, adult female rates tend to be faster than those for males. You should be familiar with these rates and how to perform the procedure. See Table 37-1 and Procedure 37-2, at the end of this chapter.

Pulse

A pulse rate gives information about the patient's cardiovascular system. It is an indirect measurement of the patient's cardiac output or the amount of blood the heart is able to

pump in one minute. If the pulse is weak or irregular, or if the patient has **tachycardia** (abnormally fast pulse) or **bradycardia** (abnormally slow pulse), the patient may have a medical problem.

Measure the pulse of adults at the radial artery, where it can be felt in the groove on the thumb side of the inner wrist. Press lightly on this pulse point with your fingers and not your thumb (a pulse is located in your thumb, and you may feel it instead of the patient's pulse). Count the number of beats you feel in a set period of time (up to 1 minute). Also note the rhythm and volume. The rhythm can be regular or irregular. The volume can be weak, strong, or bounding. A bounding pulse feels like it is leaping out and then quickly disappearing with each pulse beat and sometimes can be seen at the pulse site. You may be asked to document the pulse volume on a numerical scale from 0 to 4+. Following are the characteristics of this scale.

- 0 = no palpable pulse
- 1+ = weak
- 2+ = faint pulse
- 3+ = normal pulse
- 4+ = bounding pulse

Count the pulse for 30 seconds and, if the beat is regular, multiply the results by 2 to obtain the beats per minute. If the pulse is irregular, weak, or bounding, you must count for a full minute and document the irregularities. In some cases, you may be able to count the pulse for as little as 15 seconds and multiply by 4 to obtain the beats per minute. However, this should only be done when you are comfortable with the procedure and you are certain the pulse is normal (3+) and regular.

Pulse sites other than the radial pulse may be used for various reasons. For example, in young children, the radial artery may be hard to feel. You may instead take the pulse at the brachial artery, which is in the medial aspect of the antecubital

fossa (the bend of the elbow) or on the medial (inner) side of the upper arm. If you cannot feel the brachial pulse, then take the pulse over the apex (the left lower corner) of the heart, where the strongest heart sounds can be heard. Count the apical pulse (the heartbeat at the apex of the heart) while you listen with a **stethoscope**, an instrument that amplifies body sounds. The apex is located in the fifth intercostal space between the ribs on the left side of the chest, directly below the center of the clavicle. Consult Figure 37-6 for placement of the stethoscope. Though the condition is rare, you may encounter a patient with *dextrocardia*—a congenital condition in which the heart is pointed toward the right side of the chest. In this case, you will find the apical pulse on the right side of the chest, directly below the clavicle in the fifth intercostal space. You also may use other locations to take a pulse. Figure 37-7 shows the location of common pulse points.

Electronic Pulse The pulse may be measured electronically using a device attached to the finger or sometimes the nose or earlobe. Figure 37-8 shows one type of device used as part of an electronic blood pressure machine. A pulse oximeter machine, which measures the oxygen level of the blood, also can be used (Figure 37-9).

When using these devices, be certain to attach the clip firmly to the finger, lobe, or nose. When using a nose bridge pulse oximeter, make sure there is good skin contact. The nose bridge pulse oximeter should only be used with patients who have good peripheral circulation. See Figure 37-10. The finger clip uses an infrared light to measure the pulse and

FIGURE 37-6 A stethoscope is used over the apex of the heart to listen for the heart sounds and measure the heart rate in patients in whom pulse is not otherwise detectable.

oxygen levels, so it works best when no nail polish is present on the patient's finger. The pulse reading and the oxygen saturation of the blood will display on the screen. If the pulse is outside the normal range (see Table 37-1), it should be taken again or performed manually. If the oxygen level is less than 92%, the patient should be asked to take deep breaths during the procedure to increase her oxygen level. An oxygen level below 92% that does not improve with deep breaths should be reported.

FIGURE 37-7 There are many locations on the body where major arteries are close enough to the surface to allow a pulse to be felt and counted.

FIGURE 37-8 Pulse, blood pressure, and oxygen saturation can all be measured with this electronic blood pressure device.

© Total Care Programming, Inc.

FIGURE 37-9 A pulse oximeter measures the pulse and oxygen saturation of the blood. Attach the clip firmly to the patient's finger, as shown.

© Jim Varney/Science Source

Respiration

Respiration rate indicates how well a patient's body is providing oxygen to tissues. The best way to check respiration is by watching, listening, or feeling the movement at the patient's chest, stomach, back, or shoulders. If you cannot see the chest

FIGURE 37-10 Make sure there is good skin contact when using a nose bridge pulse oximeter.

© McGraw-Hill Education

movement, then place your hand over the patient's chest, shoulder, or abdomen and listen and feel for the movement of air.

Respirations also may be counted with a stethoscope. Place the stethoscope on one side of the patient's spine in the middle of the back to count respirations. You need to count respirations subtly because once the patient is aware that respiration is being measured, he may unintentionally alter his breathing. If using a stethoscope, tell the patient that you want to listen to his lungs. When you are not using a stethoscope, count the respirations while you have your hand on the pulse site.

Respirations are counted for 1 full minute in order to determine the rate, rhythm, and effort (quality). Counting for less than a minute may cause you to miss certain breathing abnormalities. Record the rhythm as either regular or irregular. Record the quality of effort as normal, shallow, or deep. Irregularities such as **hyperventilation** (excessive rate and depth of breathing), **dyspnea** (difficult or painful breathing), **tachypnea** (rapid breathing), or **hyperpnea** (abnormally rapid, deep, or labored breathing) are indications of possible disease and should be noted. Rales and rhonchi are types of noisy breathing that can indicate an abnormality. **Rales**—crackling sounds—indicate fluid in the lung and can be heard in patients with pneumonia, atelectasis, pulmonary edema, or other conditions. **Rhonchi**—deep snoring or rattling sounds—are associated with asthma, acute bronchitis, or any condition involving partial obstruction of the lung's airway. They may be noted in pneumonia, bronchitis, asthma, or other pulmonary diseases. Cheyne-Stokes respirations are characterized by periods of increasing and decreasing depth of respiration between periods of **apnea** (the absence of respiration). This pattern of breathing may be seen in patients with strokes, head injuries, brain tumors, and congestive heart failure.

Go to **CONNECT** to see a video exercise about
Measuring and Recording Pulse and Respirations.

► Blood Pressure

LO 37.4

Blood pressure (also known as arterial blood pressure) is the force at which blood is pumped against the walls of the arteries. The standard unit for measuring blood pressure is millimeters of mercury (mmHg). The pressure measured when the left ventricle of the heart contracts is known as the systolic pressure. The pressure measured when the heart relaxes is known as the diastolic pressure. The diastolic pressure indicates the minimum amount of pressure exerted against the vessel walls at all times.

According to the Joint National Committee of Prevention, Detection, Evaluation, and Treatment of High Blood Pressure, expected adult systolic readings are less than 120 mmHg and adult diastolic readings are less than 80 mmHg. These values may increase with advancing age. Table 37-4 outlines blood pressure classifications.

Factors Affecting Blood Pressure

High blood pressure, known as **hypertension**, is a common health problem. If the blood pressure reading is consistently elevated after two or more office visits, the patient may be diagnosed with hypertension. According to the American Heart Association, more than 76 million Americans over the age of 20 have high blood pressure. Hypertension may be categorized as essential or secondary. There is no identifiable cause for essential hypertension. According to the Joint National Committee, 95% of all hypertension is essential. Secondary hypertension occurs as a result of some other condition, such as kidney or heart disease.

Many factors affect the blood pressure. Internal factors such as cardiac output (amount of blood pumped by the heart), blood volume (amount of blood in the body), vasoconstriction (peripheral resistance), and blood viscosity (thickness) regulate the blood pressure within the body.

Malignant hypertension is high blood pressure that is high enough to cause renal or heart failure, *papilledema* (swelling of the optic nerve), or other vital organ damage. Patients with elevated blood pressure are frequently checked more than once during an office visit and may be monitoring their blood pressure at home.

Hypotension, or low blood pressure, is not generally a chronic health problem. Slightly low blood pressure may be normal for some patients and does not usually require treatment. Severe hypotension may be present with shock, heart failure, severe burns, and excessive bleeding.

TABLE 37-4 Blood Pressure Classifications

Classification	Systolic (mmHg)	Diastolic (mmHg)
Normal	Less than 120	AND less than 80
Prehypertension	120–139	OR 80–89
Stage 1 hypertension	140–159	OR 90–99
Stage 2 hypertension	Greater than 160	OR greater than 100
Hypertensive crisis (emergency care needed)	Greater than 180	OR greater than 110

Blood Pressure Measuring Equipment

Blood pressure is measured with an instrument called a **sphygmomanometer**. A sphygmomanometer consists of an inflatable cuff, a pressure bulb or automatic device for inflating the cuff, and a manometer to read the pressure. The three basic types of sphygmomanometers differ in how the pressure is displayed.

Aneroid Sphygmomanometers Aneroid sphygmomanometers have a circular gauge that registers pressure. The needle on the gauge rotates as pressure rises. This type of sphygmomanometer is very accurate as long as calibration is done on a regular basis. Each measurement line indicates 2 mmHg (Figure 37-11).

Electronic Sphygmomanometers Electronic sphygmomanometers provide a digital readout of blood pressure (Figure 37-12). Unlike aneroid sphygmomanometers, these devices do not require use of a stethoscope to determine blood pressure. They are easy to use but can be costly. Accuracy can sometimes be an issue, so maintain the equipment according to the manufacturer's instructions. If you question the results of an electronic blood pressure measurement, take it again with an aneroid cuff.

Mercury Sphygmomanometers Mercury sphygmomanometers contain a column of mercury that rises with an increase in pressure as the cuff is inflated. Mercury instruments are gradually being replaced because the government has restricted the use of mercury due to its effects on people and the environment. In 2007, the World Health Organization, in conjunction with Healthcare Without Harm, began an initiative to eliminate the use of mercury thermometers and sphygmomanometers by the year 2017. Consequently, no new mercury sphygmomanometers are being manufactured in the United States.

FIGURE 37-11 Each line on the aneroid gauge indicates 2 mmHg. To prevent inaccuracies, look directly at this gauge when performing a blood pressure test.

FIGURE 37-12 This electronic sphygmomanometer displays the patient's blood pressure, pulse, and oxygen saturation. If you question any of the results, repeat the test using a manual method.

© Total Care Programming, Inc.

Calibrating the Sphygmomanometer

To ensure that sphygmomanometers are working properly, you or a medical supply dealer must calibrate them regularly. To **calibrate** means to standardize a measuring instrument. Follow the manufacturer's instructions for an electronic sphygmomanometer.

Using an uncalibrated sphygmomanometer will result in inaccurate blood pressure readings, so do not use a sphygmomanometer unless you are certain it is calibrated. To calibrate an aneroid sphygmomanometer, follow these steps:

1. Check that the needle on the dial rests within the small square at the bottom of the dial when no pressure is applied to the cuff.
2. To calibrate the dial, use a Y connector to attach the dial to a pressure bulb and a calibrated manometer.
3. Use the pressure bulb to elevate both manometer readings to 250 mmHg. As you let the pressure fall, record both readings at four different points.
4. The difference between paired readings should not exceed 3 mmHg.
5. If the sphygmomanometer does not calibrate properly, check the manufacturer's instructions and send the sphygmomanometer for repair if needed.

The Stethoscope

A stethoscope amplifies body sounds, making them louder. It consists of earpieces, binaural tubes (one for each earpiece), rubber or plastic tubing, and a chestpiece (Figure 37-13). For best results, the earpieces should fit snugly and comfortably in your ears. When placing them in your ears, make sure the earpieces are facing forward, toward your face, for the best fit.

The chestpiece consists of two parts: the diaphragm and the bell. The diaphragm is the larger, flat side of the chestpiece, which is covered by a thin, plastic disk. The diaphragm—best at amplifying high-pitched sounds, such as bowel and lung

FIGURE 37-13 The stethoscope amplifies body sounds.

sounds—must be placed firmly against the skin for proper amplification of sound.

The bell is the cone-shaped side of the stethoscope chestpiece. It must be held lightly against the skin to amplify sound. The bell is best at amplifying low-pitched sounds, such as vascular and heart sounds. With practice, you may find you prefer to use one side rather than the other for various purposes.

Measuring Blood Pressure

To measure blood pressure, wrap the cuff of the sphygmomanometer around the patient's upper arm, just above the brachial artery's pulse point (Figure 37-14). This pulse point is located in the antecubital fossa (bend of the elbow). When measuring blood pressure, you should first determine the palpatory pressure that represents the target peak inflation. With the cuff placed just above the brachial artery pulse, palpate the radial pulse. This **palpatory method** provides an approximation of the systolic blood pressure to ensure an adequate level of inflation when the actual measurement is made. Inflate the cuff until you can no longer feel the radial pulse and note the pressure at that point. Allow the arm to rest for 30 to 60 seconds or remove the cuff and replace. Checking the chart or asking the patient his or her usual blood pressure may be helpful if you have difficulty obtaining a palpatory result. Then determine the **auscultated blood pressure**, a precise measurement of blood pressure

FIGURE 37-14 The blood pressure cuff should be 1 inch above the elbow with the center of the bladder directly above the brachial pulse.

© McGraw-Hill Education

obtained by using the sphygmomanometer with a stethoscope to amplify the heart sounds. Inflate the cuff to 30 mmHg above the palpatory result, or no more than 180 to 200 mmHg. Then, while you release the air in the cuff, listen with the stethoscope placed over the brachial pulse point. The sounds you hear are the result of blood flowing through the circulatory system. Refer to the chapter *The Cardiovascular System* for more information about heart sounds and their relationship to blood pressure readings. The heart sounds will change as the pressure in the blood pressure cuff decreases. These sounds are called Korotkoff sounds and they have five phases:

- Phase 1: The first tapping sound you hear represents the systolic pressure.
- Phase 2: A strong heartbeat changes to a softer, swishing sound.
- Phase 3: A crisp, tapping sound resumes.
- Phase 4: Sounds become muffled.
- Phase 5: The point at which the sound disappears; this represents the diastolic pressure.

Sometimes the sound will vanish temporarily between phase 1 and phase 2. This happens when the blood vessels beneath the cuff become congested and is often a sign of hypertension. When the congestion clears, the sound resumes. The period during which the sound either changes or vanishes is called the *auscultatory gap*.

Blood pressure is usually recorded with the systolic and diastolic sounds separated by a slash—for example, 116/76. If there is a pressure difference greater than 10 mmHg between the muffled sound and its disappearance, the blood pressure may be recorded with all three sounds, noted as 120/80/60. The process of taking blood pressure is described in Procedure 37-3, at the end of this chapter.

Special Considerations in Adults Blood pressure is elevated during and just after exercise. If a patient has engaged in strenuous activity before the exam, you should wait 15 minutes before taking blood pressure measurements. This waiting period also applies to patients with ambulatory disabilities, to those who are obese, and to those who have a known blood pressure problem. If you ensure that patients have relaxed for 15 minutes before you measure their blood pressure, you should get an accurate reading.

Blood pressure also may be elevated when a patient is anxious or under stress. The patient may be aware that a blood pressure reading is high or low and upset about the reading. If the patient seems stressed or upset, allow him to rest for about 5 minutes before measuring his blood pressure. To help the patient relax, try to engage the person in conversation rather than calling attention to the fact that you are waiting to take his blood pressure. If the patient still appears anxious or under stress, take his blood pressure anyway and make a notation for the licensed practitioner (who may want to repeat the measurement later in the visit).

However, there are certain instances when you should not take a blood pressure measurement on a particular arm. Blood pressure should not be taken on an arm that is on the same side as a mastectomy (breast removal) or on an arm that

has an injury, a blocked artery, or a device under the skin (implant) at the site. In such cases, use the other arm or the upper leg, placing the stethoscope over the popliteal artery behind the knee. Note the measurements and their locations in the patient's chart.

Be sure you use the proper size cuff when taking blood pressure. The bladder inside the cuff should encircle 80% to 100% the distance around the arm or leg. Although the standard adult cuff can be used for most adults, some may require the larger size. Using an improper size may result in an inaccurate reading.

Go to CONNECT to see a video exercise about Taking the Blood Pressure of Adults and Older Children.

► Orthostatic, or Postural, Vital Signs

LO 37.5

Orthostatic vital signs are taken in different positions to assess for **orthostatic**, or **postural**, **hypotension**. This means that as the patient moves from a lying to sitting or standing position, the blood pressure becomes lower and, as a result, the pulse increases. This usually indicates some sort of fluid loss or malfunctioning of the cardiovascular system, which may be the result of vomiting, diarrhea, or prolonged bed rest.

Orthostatic vital signs are taken in three different positions. Blood pressure and pulse are taken with the patient lying down, then sitting up, and then standing. The recommended interval between checking the blood pressure in the various positions is 2 to 5 minutes. This allows the body's systems to adjust between readings. Do not allow the patient's arm to hang down while taking the blood pressure because this could cause a false blood pressure increase. Instead, rest the patient's arm on the bed or table. Watch the patient carefully, because the patient is at increased risk for passing out during these position changes. If there is an increase in the pulse rate of more than 10 bpm and the blood pressure drops more than 20 points, then the patient is considered to have orthostatic hypotension. This is sometimes documented as a **positive tilt test**. A positive tilt test may be due to dehydration, heart disease, diabetes, medications, or a nervous system disorder.

► Body Measurements

LO 37.6

Certain measurements are obtained before the patient is seen by the practitioner. These include height and weight for adults and older children, and weight, length, and head circumference for infants. Usually, these measurements are taken before or after the vital signs, depending on the office policy. Depending on the patient, you may choose to take the patient's vital signs first. For example, if a patient may become upset about her weight, you should take her vital signs first so that the patient's vital signs will not be affected by the weight results. Anxiety can cause a patient's pulse, respirations, and blood pressure to increase. Follow the policy at your facility.

Measurements taken at each visit provide baseline values for a patient's current condition. Any extreme or abnormal changes may indicate a disease or disorder and should be noted for the practitioner. For children and adolescents, these measurements should be taken at each office visit, which allows the licensed practitioner to follow growth and development.

Measurements are also important in determining the extent of an injury or illness and help define certain treatment regimens. For example, dosages of some medications are based on patient weight; a wound or bruise may be measured to determine how well it is healing. These measurements also may be necessary for correct interpretation of certain diagnostic tests, such as electrocardiography.

Metric conversions for weight and height measurements are given in Tables 37-5 and 37-6. To complete these conversions yourself, review the *Points on Practice* feature, Math for Measurements.

Measuring the Weight of Adults

Measure the weight of adults and older children at each office visit. Weight should be listed in the patient's chart to the nearest quarter of a pound. In some cases it will need to be converted to metric units. See Table 37-5. The steps for weighing an adult or child are described in Procedure 37-4.

Measuring the Height of Adults

The height of an adult should be measured at the patient's initial visit and whenever a complete physical exam is performed or at least yearly. Height for older children is typically measured at each visit. Height should be measured to the nearest quarter of an inch. In some cases it will need to be converted to metric units. See Table 37-6. Measure the patient's height

TABLE 37-5 Metric Conversions for Weight

lb	kg	lb	kg	lb	kg
10	4.5	95	43.1	180	81.7
15	6.8	100	45.4	185	84.0
20	9.1	105	47.7	190	86.3
25	11.4	110	49.9	195	88.5
30	13.6	115	52.2	200	90.8
35	15.9	120	54.5	205	93.1
40	18.2	125	56.8	210	95.3
45	20.4	130	59.0	215	97.6
50	22.7	135	61.3	220	99.9
55	25.0	140	63.6	225	102.2
60	27.2	145	65.8	230	104.4
65	29.5	150	68.1	235	106.7
70	31.8	155	70.4	240	109.0
75	34.1	160	72.6	245	111.2
80	36.3	165	74.9	250	113.5
85	38.6	170	77.2		
90	40.9	175	79.5		

Note: kg = lb $\times$ 0.454; lb = kg $\times$ 2.205. Conversions are rounded to nearest tenth.

40	102				

Note: cm = in $\times$ 2.54; in = cm $\times$ 0.394. Conversions are rounded to the nearest whole number.

after weighing the patient. Most office scales have a height bar located in the center of the scale. This bar is calibrated in inches and quarter inches. The steps for measuring the height of an adult are described in Procedure 37-4.

Body Mass Index

A reliable indicator of healthy weight is **body mass index (BMI)**, which is calculated based on height and weight. If you are asked to calculate a patient's BMI, use the CDC's BMI chart (Figure 37-15). Hand-held BMI calculators are

FIGURE 37-15 Use a BMI chart to calculate a patient's body mass index.

also available. See the chapter *Nutrition and Health* for more information on healthy weight management.

Other Body Measurements

In some facilities, you may be asked to obtain other body measurements. For example, if a patient has edema (swelling) of an arm or a leg, you might be asked to measure the diameter. You should measure both arms or legs to determine the

difference in size. If a patient has a wound, bruise, or other injury, you may need to measure its length and width to evaluate the healing process. Additionally, sometimes an infant will need her chest circumference measured, or an adult may require a measurement around his abdomen, which is known as *abdominal girth*. Infant vital signs and measurements are described in more detail in the *Assisting in Pediatrics* chapter.

PROCEDURE 37-1 Measuring and Recording Temperature

WORK // DOC

Procedure Goal: To accurately measure patient temperature while preventing the spread of infection

OSHA Guidelines:

Materials: Thermometer, probe cover if required by thermometer, lubricant for rectal temperature, gloves, trash receptacle, patient's chart or progress note, and a black pen if recording in a paper record

Method:

1. Gather the equipment and make sure the thermometer is in working order.
2. Identify the patient and introduce yourself.
3. Wash your hands and explain the procedure to the patient.
4. Prepare the patient.
 - a. *Oral.* If the patient has had anything to eat or drink, or has been smoking, wait at least 15 minutes before measuring the temperature orally.
RATIONALE: *Inaccurate reading could result.*
 - b. *Rectal.* Have the patient remove the appropriate clothing; assist as needed. Have the patient lie on his or her left side and drape for comfort.
RATIONALE: *Proper positioning is necessary for the patient's safety and comfort.*
 - c. *Axillary.* Assist the patient to expose the axilla. Provide for privacy and comfort. Pat dry the axilla.
RATIONALE: *Perspiration or heavy deodorant prevents the thermometer from coming in direct contact with the skin.*
 - d. *Temporal or tympanic.* If the patient is wearing a hat, ask the patient to remove it.
5. Prepare the equipment.
 - a. Prepare an electronic thermometer by inserting the probe into the probe cover if necessary.

RATIONALE: *Probe covers are needed to prevent contamination of the probe.*

- b. Prepare a disposable thermometer by removing the wrapper to expose the handle end. Avoid touching the part of the thermometer that goes in the mouth or on the skin.

RATIONALE: *Touching the thermometer could interfere with an accurate reading.*

- c. Prepare a temporal scanner by removing the protective cap and making sure the lens is clean.

RATIONALE: *This will ensure an accurate reading.*

6. Measure the temperature.

- a. *Oral.* Place the thermometer under the tongue in the back of the mouth on one side. Have the patient hold it in place with his or her lips and tongue. Wait for the electronic thermometer to beep or indicate completion. For a disposable thermometer, wait the required time, usually 60 seconds.
- b. *Rectal.* Put on gloves. Lubricate the thermometer tip. Raise the buttock with one hand to expose the anus and insert the thermometer into the anal canal using your other hand, approximately 1 inch for adults and ½ inch for infants and children. Hold the thermometer securely in place until the indicator beeps or blinks.

RATIONALE: *Injury could occur if the thermometer is inserted too far or if the patient moves during the procedure.*

- c. *Axillary.* Place the thermometer into the axilla, making sure the tip is in direct contact with the top of the axilla and is touching skin on all sides. Hold the arm firmly against the body until the indicator light blinks or beeps or the proper amount of time has passed.

RATIONALE: *Ensures accuracy.*

- d. *Tympanic.* Hold the outer edge of the ear (pinna) with your free hand. Gently pull the pinna up for adults and down for children (see figure). Insert the probe into the ear canal directed toward the eardrum and sealing the ear canal. Press the scan button.

(a)

(b)

FIGURE Procedure 37-1 Step 6d When placing a tympanic thermometer, seal the ear canal by holding the pinna (outer ear) upward and outward for an adult (a) and downward and backward for a child (b).

© McGraw-Hill Education

RATIONALE: Ensures accuracy.

- e. *Temporal.* Position the probe flat on the center of the exposed forehead. Press and hold the SCAN button and then slide the thermometer straight across the forehead until it beeps and the red light blinks.

FIGURE Procedure 37-1 Step 6e A temporal scanner is a safe, fast, and noninvasive method for taking temperature.

© McGraw-Hill Education

7. Remove and read the measurement in the display or on the thermometer. Discard the disposable thermometer. Eject and discard the probe cover for an electronic thermometer. Replace the cap and/or place the thermometer into the charging base.

RATIONALE: Contaminated items should be removed and the thermometer should be protected and charged until the next use.

8. Record the results. Chart by including the date and location where the temperature was taken.

- Oral: 98.6
- Rectal: 99.6 R
- Axillary: 97.6 Ax
- Temporal: 97.6 Temp or TA
- Tympanic: 97.6 Tymp

RATIONALE: The temperature varies depending upon the location; this location should be charted to ensure an accurate diagnosis.

9. Help the patient to replace clothing as necessary. Clear the area and provide for safety and comfort for the patient.
10. Wash your hands.

PROCEDURE 37-2 Measuring and Recording Pulse and Respirations

WORK // DOC

Procedure Goal: To accurately measure a patient's pulse and respirations while keeping the patient unaware the respirations are being counted

OSHA Guidelines:

Materials: Watch with a second hand, patient's chart or progress note, and black pen if recording in a paper chart

Method:

1. Gather the equipment and wash your hands.
2. Introduce yourself and identify the patient.
3. Explain the procedure, saying, "I am going to take your vital signs. We'll start with your pulse first." Do not tell him you are counting the respirations.
RATIONALE: If the patient is aware you are counting respirations, he may unconsciously change his breathing rate.
4. Ask the patient to sit or lie in a comfortable position. Have the patient rest his arm on a table. The palm should be facing downward.

5. Position yourself so you can observe and/or feel the chest wall movements. You may want to lay the patient's arm over the chest to feel the respiratory chest movements.
6. Place two or three fingers on the radial pulse site. Find the radial bone on the thumb side of the wrist; then slide your fingers into the groove on the inside of the wrist to locate the pulse.
7. Count the pulse for 30 seconds if regular. Note the rhythm and volume. If irregular, count for a full minute. Remember or note the number.

RATIONALE: *An irregular pulse is counted for a full minute to ensure accuracy and to note abnormalities.*

8. Without letting go of the wrist, observe and feel the respirations, counting for 1 full minute. Observe for rhythm, volume, and effort.
9. Once you are certain of both numbers, release the wrist and record them. If the pulse was measured for less than 1 minute, obtain the number of beats per minute. Multiply the number of beats counted in 30 seconds by 2.
10. Document results with the date and time (example: 6/18/16 P 88 regular and strong R 16 regular).
11. Report any findings that are a significant change from a previous result or outside the normal values, as shown in Table 37-1.

PROCEDURE 37-3 Taking the Blood Pressure of Adults and Older Children

WORK // DOC

Procedure Goal: To accurately measure blood pressure in adults and older children

OSHA Guidelines:

Materials: Sphygmomanometer, stethoscope, alcohol gauze squares, patient's chart or progress note, and black pen if recording in a paper chart

Method:

1. Gather the equipment and make sure the sphygmomanometer is in working order and correctly calibrated.
RATIONALE: *Calibration helps ensure an accurate result.*
2. Identify the patient and introduce yourself.
3. Wash your hands and explain the procedure to the patient.
4. Have the patient sit in a quiet area. If she is wearing long-sleeved clothing, have her loosely roll up one sleeve. If she cannot, have her change into a gown.
5. Have the patient rest her bared arm on a flat surface so that the midpoint of the upper arm is at the same level as the heart.
RATIONALE: *Doing so helps ensure an accurate reading.*
6. Select a cuff that is the appropriate size for the patient. The bladder inside the cuff should encircle 80% of the arm in adults and 100% of the arm in children younger than the age of 13. If you are not sure about the size, use a larger cuff.
RATIONALE: *Using the proper cuff size helps ensure an accurate reading.*
7. Locate the brachial artery in the antecubital space.
8. Position the cuff so that the midline of the bladder is above the arterial pulsation. Then wrap and secure the cuff

snugly around the patient's bare upper arm. The lower edge of the cuff should be 1 inch above the antecubital space, where the head of the stethoscope is to be placed.

RATIONALE: *If the blood pressure cuff touches the stethoscope, it could interfere with your ability to hear.*

9. Place the manometer so that the center of the aneroid dial is at eye level and easily visible and so that the tubing from the cuff is unobstructed.
10. Close the valve of the pressure bulb until it is finger-tight.
11. Inflate the cuff rapidly to 70 mmHg with one hand and increase this pressure in 10 mmHg increments while palpating the radial pulse with your other hand. Note the level of pressure at which the pulse disappears and subsequently reappears during deflation. This procedure is the palpatory method.
12. Open the valve to release the pressure, deflate the cuff completely, and wait at least 30 seconds or remove and replace the cuff.
RATIONALE: *If you do not deflate the cuff completely and wait, blood may pool in the artery and give a falsely high reading.*
13. Place the earpieces of the stethoscope in your ear canals and adjust them to fit snugly and comfortably. When placed in the ears, they should point toward the nose. Switch the stethoscope head to the diaphragm position. Confirm the setting by listening as you tap the stethoscope head gently.
14. Place the head of the stethoscope over the brachial artery pulsation, just above and medial to the antecubital space but below the lower edge of the cuff. Hold the stethoscope firmly in place using your index and middle fingers, making sure the head is in contact with the skin around its entire circumference.
RATIONALE: *Do not hold the stethoscope with your thumb because the pulse of your thumb can interfere with the reading.*

15. Inflate the bladder rapidly and steadily to a pressure 30 mmHg above the level previously determined by the palpatory method. Then partially open (unscrew) the valve and deflate the bladder at approximately 2 mm per second while you listen for the Korotkoff sounds.
16. As the pressure in the bladder falls, note the level of pressure on the manometer at the first appearance of repetitive sounds. This reading is the systolic pressure.
17. Continue to deflate the cuff gradually, noting the point at which the sound changes from strong to muffled.
18. Continue to deflate the cuff, and note when the sound disappears. This reading is the diastolic pressure.
19. Continue to listen for an additional 10 mmHg, listening carefully for a return of the repetitive sounds.

RATIONALE: *Continue listening to ensure that the lack of sound is not the result of an auscultatory gap.*

20. Deflate the cuff completely and remove it from the patient's arm.
21. Record the systolic and diastolic numbers, separated by a slash, in the patient's chart. Chart the date and time of the measurement, the arm on which the measurement was made, the subject's position, and the cuff size when a nonstandard size is used. The value recorded is an exact measurement of the auscultated blood pressure.
22. Fold the cuff and replace it in the holder.
23. Inform the patient that you have completed the procedure.
24. Disinfect the earpieces and diaphragm of the stethoscope with gauze squares moistened with alcohol.
25. Properly dispose of the used gauze squares and wash your hands.

PROCEDURE 37-4 Measuring Adults and Children

WORK // DOC

Procedure Goal: To accurately measure weight and height of adults and children

OSHA Guidelines:

Materials: For an adult or older child, adult scale with height bar, disposable towel; for toddler, adult scale with height bar or height chart, disposable towel, patient chart/progress note

Method:

Adult or Older Child: Weight

1. Identify the patient and introduce yourself.
2. Wash your hands and explain the procedure to the patient.
3. Check to see whether the scale is in balance by moving all the weights to the left side. The indicator should be level with the middle mark. If not, check the manufacturer's directions and adjust it to ensure a zero balance. If you are using a scale equipped to measure either kilograms or pounds, check to see that it is set on the desired units and that the upper and lower weights show the same units.
RATIONALE: *Proper functioning of the scale helps ensure an accurate result.*
4. Ask the patient to remove her shoes, if that is the standard office policy.
RATIONALE: *Follow the policy and use the same procedure for all visits for consistency of results.*
5. Place a disposable towel on the scale or have the patient leave her socks on.

RATIONALE: *Prevents cross-contamination of the scale from various patients' feet*

6. Ask the patient to step on the center of the scale, facing forward. Assist as necessary.
7. Place the lower weight at the highest number that does not cause the balance indicator to drop to the bottom.
RATIONALE: *To ensure accuracy*
8. Move the upper weight slowly to the right until the balance bar is centered at the middle mark, adjusting as necessary.
RATIONALE: *To ensure accuracy*
9. Add the two weights together to get the patient's weight.
10. Record the patient's weight in the chart to the nearest quarter of a pound or tenth of a kilogram.
11. Return the weights to their starting positions on the left side.

Adult or Older Child: Height

12. With the patient off the scale, raise the height bar well above the patient's head and swing out the extension. (This can also be done before the patient steps on the scale for his weight measurement.)
RATIONALE: *Doing so prevents hitting the patient with the extension bar.*
13. Ask the patient to step on the center of the scale and to stand up straight and look forward.
RATIONALE: *Standing straight is necessary for accuracy.*
14. Gently lower the height bar until the extension rests on the patient's head.
15. Have the patient step off the scale while you hold the height bar before reading the measurement.
RATIONALE: *To better visualize the height measurement*

FIGURE Procedure 37-4 Step 14 The medical assistant adjusts the height bar to meet the top of the patient's head.

© McGraw-Hill Education

16. If the patient is fewer than 50 inches tall, read the height on the bottom part of the ruler; if the patient is more than 50 inches tall, read the height on the top, movable part of the ruler at the point at which it meets the bottom part of the ruler. Note that the numbers increase on the bottom part of the bar and decrease on the top, movable part of the bar. Read the height in the right direction.
17. Record the patient's height.
18. Have the patient put shoes back on, if necessary.
19. Properly dispose of the used towel and wash your hands.

Toddler: Weight

1. Identify the patient and obtain permission from the parent to weigh the toddler.
2. Wash your hands and explain the procedure to the parent.
3. Check to see whether the scale is in balance and place a disposable towel on the scale or have the patient wear shoes or socks, depending on the facility's policy.
4. Ask the parent to hold the patient and to step on the scale. Follow the procedure for obtaining the weight of an adult.
5. Have the parent put the child down or hand the child to another staff member.
6. Obtain the parent's weight.
RATIONALE: *This is done to find the difference between the two weights.*
7. Subtract the parent's weight from the combined weight to determine the child's weight.
8. Record the patient's weight in the chart to the nearest quarter of a pound or tenth of a kilogram.

Toddler: Height

9. Measure the child's height in the same manner as you measure adult height, or have the child stand with her back against the height chart. Measure height at the crown of the head.
10. Record the height in the patient's chart.
11. Properly dispose of the towel (if used) and wash your hands.
RATIONALE: *Doing so prevents infection.*

SUMMARY OF LEARNING OUTCOMES	
LEARNING OUTCOMES	KEY POINTS
37.1 Describe the vital signs.	Vital signs include temperature, pulse, respirations, and blood pressure; some practitioners also consider pain assessment to be one of the vital signs.
37.2 Identify various methods of taking a patient's temperature.	Using either an electronic digital or disposable thermometer, a patient's temperature may be measured by the oral, tympanic, rectal, axillary, or temporal method.
37.3 Describe the process of obtaining pulse and respirations.	Pressing lightly at the radial artery using your fingers, count the number of beats you feel in 1 minute to get the pulse. While still keeping fingers on the patient's pulse site, observe and feel the patient's respirations, and count the respirations for 1 full minute. See Procedure 37-2.
37.4 Carry out blood pressure measurements.	To obtain a blood pressure, have the patient sit in a quiet area, rest his or her bared arm on a flat surface at heart level, locate the brachial artery, snugly secure the cuff above the brachial artery, use the palpatory method to determine the approximate systolic pressure, and use a stethoscope to auscultate the systolic and diastolic blood pressure.

LEARNING OUTCOMES**37.5 Summarize orthostatic, or postural, vital signs.****KEY POINTS**

Orthostatic, or postural, vital signs consist of taking the blood pressure and pulse in different positions, from lying to sitting to standing, waiting 2 to 5 minutes between repositioning to allow the body's systems to adjust to the change.

37.6 Illustrate various body measurements.

For adults and older children, the measurements obtained are the height and weight; for infants, they are the weight, length, and head circumference. See Procedure 37-4. BMI, extremities, and wounds are also measured according to facility policy and patient condition.

C A S E S T U D Y C R I T I C A L T H I N K I N G

Recall Mohammad from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. Why is an accurate measurement and recording of Mohammad's vital signs critical in this case?

- 2.** After examining Mohammad and ordering and reviewing the results of an ECG test, Dr. Williams indicates that Mohammad's heart appears to be normal. What factors might be contributing to Mohammad's episodes of tachycardia?
- 3.** The physician is going to give Mohammad an injection and needs to know his weight in kilograms. You measured his weight as 140 pounds. Convert this weight to kilograms.

E X A M P R E P A R A T I O N Q U E S T I O N S

- (LO 37.4) If a patient's blood pressure is 138/82, it is considered
 - Normal
 - Hypotension
 - Prehypertension
 - Stage 1 hypertension
 - Stage 2 hypertension
- (LO 37.1) When taking a patient's oral temperature, you should wear gloves if
 - The patient is in for a routine physical exam
 - There are contact precautions for the patient
 - The patient is less than 5 years old
 - You suspect the patient has a fever
 - The patient cannot hold the thermometer in her mouth
- (LO 37.2) Using the formula to convert degrees Fahrenheit to degrees Celsius, determine which of the following is equal to 99.8°F (round to the nearest tenth).
 - 37.7°C

Go to CONNECT to see an animation exercise about *Hypertension.*

SOFT SKILLS SUCCESS

The electronic pulse oximeter is in use and, although you would rather not do it, you take the patient's pulse manually. While counting the pulse you notice it seems irregular and every so often it seems to feel stronger. You look at the patient who appears pale and has a slight grimace on his face. What should you do?

Go to PRACTICE MEDICAL OFFICE and complete the module *Clinical - Office Operations.*

Assisting with a General Physical Examination

38

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Valarie Ramirez	8/4/19XX	Penicillin
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	829-78-462	Previous eye injury Denies pain or blurred vision

Valarie Ramirez, a 33-year-old female, is at the office for a pre-employment general physical exam. Her vital signs are BP 122/80, T 98.6 P 84 R 20, height 62 inches, and weight 140 pounds. While you are interviewing her, she shows you

© McGraw-Hill Education

a wart on her right hand and says it is very painful and would like it taken off.

Keep Valarie Ramirez in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 38, you will be able to:

- 38.1** Identify the purpose of a general physical exam.
- 38.2** Describe the role of the medical assistant in a general physical exam.
- 38.3** Explain safety precautions used during a general physical exam.
- 38.4** Carry out the steps necessary to prepare the patient for an exam.
- 38.5** Carry out positioning and draping a patient in each of the nine common exam positions.
- 38.6** Apply techniques to assist patients from different cultures and patients with physical disabilities.
- 38.7** Identify the six examination methods used in a general physical exam.
- 38.8** List the components of a general physical exam.
- 38.9** Describe follow-up steps after a general physical exam.

- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.9** Assist provider with a patient exam
- III.P.2** Select appropriate barrier/personal protective equipment (PPE)
- V.P.3** Use medical terminology correctly and pronounced accurately to communicate information to providers and patients
- V.P.5** Coach patients appropriately considering:
 - (a) cultural diversity
 - (c) communication barriers
- X.P.3** Document patient care accurately in the medical record

2. Anatomy and Physiology

- c. Identify diagnostic and treatment modalities as they relate to each body system

5. Psychology of Human Relations

- c. Intervene on behalf of the patient regarding issues/concerns that may arise, i.e. insurance policy information, medical bills, physician/provider orders, etc.

8. Medical Office Business Procedures Management

- f. Display professionalism through written and verbal communications

9. Medical Office Clinical Procedures

- a. Practice standard precautions and perform disinfection/sterilization techniques
- b. Obtain vital signs, obtain patient history, and formulate chief complaint
- c. Assist provider with general/physical examination
- h. Teach self-examination, disease management and health promotion
- j. Make adaptations with patients with special needs

► Introduction

Whether a patient comes for a regular checkup or to have a problem diagnosed and treated, the physical exam is the first step in the process for the physician or other licensed practitioner. As the medical assistant, your role during the physical exam is to make the patient comfortable and assist the physician as necessary. A skilled medical assistant who is sensitive to patient needs and proficient in performing these skills can create an atmosphere that results in a positive outcome for the patient during the exam.

► The Purpose of a General Physical Exam

LO 38.1

Physicians perform general physical exams for two purposes. The first is to examine a healthy patient to confirm an overall state of health and to provide baseline values for vital signs and measurements. The second is to examine a patient to diagnose a medical problem.

To confirm a patient's health status, physicians usually perform exams on a routine basis, such as once a year. Some exams are done to fulfill a requirement before an individual starts school, begins a new job, or starts an exercise program.

When a physician performs an examination to diagnose medical problems, she usually focuses on a particular organ

system. The organ system is indicated to the physician by the patient's condition and chief complaint. Because organ systems are so interdependent, however, physicians generally perform an overall physical exam even when a specific medical problem exists.

During a general physical exam, physicians check all the major organs and body systems. They can determine much about a patient's general condition of health from the exam. If appropriate, they also try to make an initial, or **clinical, diagnosis**—a diagnosis based on the signs and symptoms of a disease. A **sign** is objective information that can be detected by a person other than the affected person. Some examples of signs are blood in the stool and a bloody nose. A **symptom** is subjective information supplied by the patient. Anxiety, back pain, abdominal pain, and fatigue are examples of symptoms. Only the patient can perceive these sensations, which are typically part of the chief complaint.

After forming an initial diagnosis of a patient's problem, physicians may order laboratory or other diagnostic tests. These tests are done to confirm a clinical diagnosis or to rule out other possible disorders and are necessary when a patient has symptoms that may indicate more than one condition. Determining the correct diagnosis when two or more diagnoses are possible is called making a **differential diagnosis**.

Laboratory and diagnostic tests also may aid physicians in developing a **prognosis**, or a forecast of the probable course and outcome of the disorder and the prospects of recovery.

In addition, such tests help physicians formulate a treatment plan or appropriate drug therapy. Physicians may ask to have these tests repeated as part of the follow-up evaluation of a patient's progress.

► The Role of the Medical Assistant LO 38.2

Your job as a medical assistant is to assist both the licensed practitioner and the patient during the general physical exam. Your role starts before the actual exam. First, you interview the patient, document an accurate history, determine vital signs, and measure weight and height.

Generally, your responsibilities during the exam include ensuring all instruments and supplies are readily available to the licensed practitioner. You also ensure that patients are physically and emotionally comfortable during the exam by helping them into position and keeping them aware of what is going to happen. It is important to observe the patient for signs that indicate distress or the need for assistance. Providing comfort and safety to the patient and competent assistance to the physician are key during a general physical exam.

► Safety Precautions LO 38.3

As you prepare for and assist with a general physical exam, you will practice safety measures. Some of these are outlined by the Department of Labor's Occupational Safety and Health Administration (OSHA) and the Department of Health and Human Services' Centers for Disease Control and Prevention (CDC). Recall that OSHA standards and guidelines are designed to protect employees and make the workplace safe. The CDC establishes the guidelines intended to protect both patients and healthcare professionals in the medical office and the hospital setting. Taken together, these safety measures help protect you, the physician, and the patient from disease transmission.

Safety measures that you must take before, during, and after a general physical exam include the following:

- Perform a thorough aseptic handwashing before and after contact with each patient and before and after each procedure. Waterless, alcohol-based hand cleanser may be used between patients if no gross contamination or visible soilage is on your hands. Refer to the chapter *Infection Control Fundamentals* for a review of these procedures.
- Wear gloves whenever there is a possibility that you may come in contact with blood, body fluids, nonintact skin, or moist surfaces, both during the patient exam and when handling specimens.
- Instruct symptomatic patients to maintain respiratory hygiene/cough etiquette by covering their mouth and nose when coughing; using tissues and disposing of them in a no-touch receptacle; observing hand hygiene; and wearing a surgical mask or maintaining a distance of greater than 3 feet if possible. See the chapter *Infection Control Practices* for more information about respiratory hygiene/cough etiquette.

- Wear a mask in the presence of a patient suspected of having an infectious disease that is transmitted by airborne droplets, such as tuberculosis (TB) or meningitis.
- Patients with highly contagious infectious diseases, such as diphtheria or chickenpox, must be examined under isolation precautions, such as in a private room. Wear personal protective equipment (PPE) during contact. Table 38-1 provides a summary of necessary PPE based on specific diseases. Refer to the chapter *Infection Control Practices* for additional information.
- Discard in biohazardous waste containers all disposable equipment and supplies that come in contact with a patient's blood or body fluids.
- Clean and disinfect the exam room following each patient's exam.
- Sanitize, disinfect, and sterilize equipment, as appropriate, after each patient's exam.

► Preparing the Patient for an Exam LO 38.4

As a medical assistant, you will need to prepare the patient both emotionally and physically.

Emotional Preparation

To prepare patients, begin by explaining exactly what will occur during the exam. Use simple, direct language that patients can understand. Describe what patients can expect to feel and how their cooperation can contribute to the procedure's success. As discussed in the *Assisting in Pediatrics* chapter, emotional preparedness is particularly important when dealing with children, who deserve to have the same sort of information and reassurance as adults. Mature adults may require special attention to communication during emotional preparation, as discussed in the *Assisting in Geriatrics* chapter.

If you are a male medical assistant, a female physician may ask you to remain in the room when she examines a male patient. Likewise, if you are a female medical assistant, a male physician may ask you to remain in the room when he examines a woman. These measures are for the protection of both the patient and the physician. Such policies depend on the standard procedures in each medical practice or facility.

Physical Preparation

To ensure the patient is physically prepared before the physician enters the exam room, give the patient an opportunity to empty his bladder and/or bowels in order to be more comfortable during the exam. Collect a urine specimen at this time, if needed.

Ensure the room temperature is comfortable and when the patient is ready, ask him to disrobe and put on an exam gown or cover himself with a drape. The extent of disrobing depends on the type of exam and the physician's preference. If the physician requests a gown for the patient, show the patient how to put on the gown. Include specific instructions

TABLE 38-1 PPE for Infection and Precaution Type

Infection	Precaution Type	Appropriate PPE
Abscess	Contact	Gloves and gown
AIDS	Standard	Use appropriate PPE when exposed to blood or body fluids.
Anthrax	Standard	Use appropriate PPE when exposed to blood or body fluids.
Chickenpox (varicella)	Airborne/contact	Respirator (or mask and goggles) and gloves
Diphtheria • Cutaneous • Pharyngeal	Contact droplet	Gloves and gown Mask and goggles when working within 3 feet of patient
Gastroenteritis	Standard/contact	Use appropriate PPE when exposed to blood or body fluids; avoid contact with fecal material by donning gloves and gown.
Hepatitis • A • B • C • E	Contact Standard Standard Standard	Gloves and gown Use appropriate PPE when exposed to blood or body fluids. Use appropriate PPE when exposed to blood or body fluids. Use appropriate PPE when exposed to blood or body fluids.
Herpes zoster (shingles)	Contact	Gloves and gown; <i>note</i> : individuals who have not had chickenpox should avoid contact with patients with shingles.
Influenza	Droplet	Mask and goggles when working within 3 feet of patient
Measles	Airborne	Mask and goggles or respirator
Meningitis	Standard/droplet	Use appropriate PPE when exposed to blood or body fluids; use mask and goggles when working within 3 feet of patient.
Mumps	Droplet	Mask and goggles when working within 3 feet of patient
Pertussis	Droplet	Mask and goggles when working within 3 feet of patient
Poliomyelitis	Standard	Use appropriate PPE when exposed to blood or body fluids.
Rotavirus	Contact	Gloves and gown
Rubella	Droplet	Mask and goggles when working within 3 feet of patient
Scabies	Contact	Gloves and gown
Staphylococcal disease	Contact	Gloves and gown
Streptococcal disease	Contact/droplet	Gloves, gown, mask, and goggles
Tuberculosis	Airborne	Mask and goggles or respirator

on whether the gown should open in the back or front and whether it should be left open or tied. Leave the exam room while the patient disrobes to give him privacy, unless he needs and requests assistance.

Be aware of the patient's modesty and comfort at all times. Imagine what it feels like to visit a physician and, as you disrobe and put on the gown, you notice that it is too small and it's beginning to tear. In order to ensure patient comfort, make sure a variety of sizes are available for patient use. Use your critical thinking skills when selecting a patient gown. Your patient will remember this gesture and appreciate your consideration.

► Positioning and Draping

LO 38.5

During the exam, the patient may need to assume a variety of positions, which facilitate the physician's exam of certain areas of the body. The physician will indicate which positions

are needed for specific exams. You may need to help the patient assume these positions. Depending upon the patient's mobility (ability to move), you may need to help transfer, lift, and move the patient. To protect yourself from injury when helping to positioning a patient, always follow the basic rules of good **body mechanics**. Body mechanics is the application of physical principles to help prevent stress and injury to healthcare practitioners who are lifting, moving and positioning patients:

- Lifting with your strongest muscles, including your legs and arms, rather than your back
- Keeping your feet apart
- Bending from the hip and knees

Some positions are embarrassing or physically uncomfortable for patients. If you perceive embarrassment, explain the need for the position and help the patient assume the position

when necessary. Consider cultural differences and be understanding to each individual's needs. Most important, help minimize the time a patient spends in any embarrassing or uncomfortable position.

If a patient is physically uncomfortable in a position, you may be able to ease the discomfort by using a small pillow to support part of the body. You may have to help the patient maintain a position during the exam. Always try to make the patient as comfortable as possible.

When you need to make changes in the patient's position, do so gradually. If your office is equipped with an examining table that can be adjusted automatically, learn to use the controls efficiently to maximize patient comfort. Always tell the patient what movement to expect.

When patients have assumed the correct position, cover them with an appropriate drape. Drapes vary in size. Make sure you choose one that will help keep the patient warm and maintain privacy. You will position drapes differently depending on the exam position and the parts of the patient's body that the physician examines.

Exam Positions

The following are the positions commonly used during a medical exam (see Figure 38-1):

- Sitting
- Supine (recumbent)
- Dorsal recumbent
- Lithotomy
- Fowler's
- Prone
- Sims'
- Knee-chest or knee-elbow
- Proctologic

Sitting In the sitting position, the patient sits at the edge of the examining table without back support (see Figure 38-1a). The physician examines the patient's head, neck, chest, heart, back, and arms. While the patient is in the sitting position, the physician evaluates the patient's ability to fully expand the

FIGURE 38-1 These positions may be used during the general physical examination.

lungs. She then checks the upper body parts for **symmetry**, the degree to which one side is the same as the other. In the sitting position, the drape is placed across the patient's lap for men or across the patient's chest and lap for women.

If a patient is too weak to sit unsupported, another position is necessary, such as the supine position.

Supine (Recumbent) In the supine, or recumbent, position, the patient lies flat on the back with the hands to the side (Figure 38-1b) or on the abdomen. (*Supine* means "lying down face-up"; *recumbent* means "lying down." Both terms are used to describe this position.) This is the most relaxed position for many patients. A physician can examine the head, neck, chest, heart, abdomen, arms, and legs when a patient is in this position. The patient is normally draped from the neck or underarms down to the feet.

The supine position may not be comfortable for patients who become short of breath easily or for a pregnant patient late in her pregnancy. Also, patients with a back injury or lower back pain may find it uncomfortable. You can make these patients more comfortable by placing pillows under their head and knees. Some patients, however, may need to be placed in the dorsal recumbent position.

Dorsal Recumbent In the dorsal recumbent position, the patient lies face-up, with the back supporting all the weight. (The term *dorsal* refers to the back.) This position is the same as the supine position, except the patient's knees are drawn up and the feet are flat on the table, as shown in Figure 38-1c. Again, the hands can be at the patient's side or on the abdomen. The physician may examine the head, neck, chest, and heart while a patient is in this position. The patient is normally draped from the neck or underarms down to the feet.

Patients who have leg disabilities may find the dorsal recumbent position uncomfortable or even impossible. On the other hand, patients who are elderly or have painful disorders such as arthritis or back pain may find the dorsal recumbent position more comfortable than the supine position because the knees are bent. This position is sometimes used as an alternative to the lithotomy position when patients have severe arthritis or joint deformities.

Lithotomy The lithotomy position is used during examination of the female genitalia. In this position, the patient lies on her back with her knees bent and her feet in stirrups attached to the end of the examining table. You may need to help the patient place her feet in the stirrups. She should then slide forward to position her buttocks near the edge of the table, as shown in Figure 38-1d.

Many women are embarrassed and physically uncomfortable in this position, so you should not ask a patient to remain in this position any longer than necessary. Use a large drape that covers the patient from the breasts to the ankles. Placing the drape with one point or corner between the legs will make the exam easier in this position.

A patient with severe arthritis or joint deformities in the hips or knees may have difficulty assuming the lithotomy position. She may be able to place only one leg in the stirrup,

or she may need your assistance in separating her thighs. An alternative position for such a patient is the dorsal recumbent position. Other patients who may have difficulty with the lithotomy position are those who are obese or in the late stages of pregnancy.

Fowler's In Fowler's position, the patient lies back on an examining table on which the head is elevated at a 45-degree angle, as shown in Figure 38-1e. The physician may examine the head, neck, and chest areas while the patient is in this position. The patient is usually draped from the neck or underarms down to the feet.

Fowler's position is one of the best positions for examining patients who are experiencing shortness of breath or and patients with a lower back injury.

Prone In the prone position, the patient is lying flat on the table, facedown. The patient's head is turned to one side, and the arms are placed at the sides or bent at the elbows, as shown in Figure 38-1f. The patient is normally draped from the upper back to the feet.

With the patient in this position, the physician can examine the back, feet, or musculoskeletal system. The prone position is unsuitable for women in advanced stages of pregnancy, obese patients, patients with respiratory difficulties, and the elderly.

Sims' In the Sims' position, the patient lies on the left side. The patient's left leg is slightly bent, and the left arm is placed behind the back so the patient's weight is resting primarily on the chest. The right knee is bent and raised toward the chest, and the right arm is bent toward the head for support, as shown in Figure 38-1g. The patient is draped from the upper back to the feet.

Sims' position is used during anal or rectal exams and may also be used for perineal and certain pelvic exams. Patients with joint deformities of the hips and knees may have difficulty assuming this position.

Knee-Chest or Knee-Elbow In the knee-chest position, the patient is lying on the table facedown, supporting the body with the knees and chest. The patient's thighs should be at a 90-degree angle to the table and slightly separated. The head is turned to one side, and the arms are placed to the side or above the head. The patient may need your assistance to assume this position correctly and to maintain it during the exam.

The knee-chest position is used during exams of the anal and perineal areas and during certain proctologic procedures. Some patients—those who are pregnant, obese, or elderly—may have difficulty assuming this position. An alternative that puts less strain on the patient and is easier to maintain is the knee-elbow position, shown in Figure 38-1h. This position is the same as the knee-chest position except that the patient supports body weight with the knees and elbows rather than the knees and chest. In either of these two positions, the patient is commonly covered with a **fenestrated drape**, in which a special opening provides access to the area to be examined.

Proctologic The proctologic, or jackknife, position may be used as an alternative to the Sims' or knee-chest position. In the proctologic position, the patient is bent at the hips at a 90-degree angle. The patient can assume this position by standing next to the examining table and bending at the waist until the chest rests on the table. If an adjustable examining table is available, the patient can assume the position by lying prone on the table, which is then raised in the middle with both ends pointing down. This places the patient at the correct 90-degree angle, as shown in Figure 38-1i. In either variation of this position, the patient is draped with a fenestrated drape, as in the knee-chest position.

The steps for placing patients into these positions are described in Procedure 38-1 at the end of this chapter.

► Special Patient Considerations LO 38.6

Patients from other cultures and patients with disabilities may require special considerations during a general physical exam.

Patients from Different Cultures

You can expect to assist with a general physical exam for patients from other cultures. A **culture** is defined as a pattern of assumptions, beliefs, and practices that shapes the way people think and act. Avoid the temptation to stereotype an individual or group on the basis of a single patient's behavior. Stereotyping can lead to incorrect judgments, which may influence the care you provide to patients. Avoid making judgments about patients or cultural groups on the basis of your experience with other patients or with your own family and friends. Remember, if their culture is different from yours, then your culture also seems different to them.

Patients from different cultures may not be familiar with the medical exam and may not know what to expect. These patients may be more modest than other patients and may have a greater need for privacy. They may not want the physician to examine certain areas of their bodies. Procedure 38-2, at the end of this chapter, describes techniques you can use to help ensure effective communication with patients from other cultures while meeting their privacy needs.

Patients with Physical Disabilities

Patients with physical disabilities have different strengths and weaknesses and vary in their ability to ambulate (move from place to place). Many patients with physical disabilities require the use of wheelchairs, canes, walkers, or other equipment that permits or enhances mobility.

Depending on the extent of their disability, these patients may require extra assistance in preparing for a general physical exam. You may need to help them disrobe, move from a

mobility device to the examining table, and assume certain positions on or off the examining table. At all times, you should ask another staff member for assistance if you are not sure whether you can safely move or lift a patient on your own. Procedure 38-3, at the end of this chapter, outlines the steps you would take to transfer a patient from a wheelchair to the examining table.

► Exam Methods LO 38.7

The six methods for examining a patient during a general physical exam enable the practitioner to gather important information about the patient's condition. Although practitioners may have their own preference, the methods are normally performed in the following sequence:

1. Inspection
2. Auscultation
3. Palpation
4. Percussion
5. Mensuration
6. Manipulation

Inspection

Inspection is the visual exam of the patient's entire body and overall appearance. During inspection, the physician assesses posture, mannerisms, and hygiene. The physician also inspects parts of the body for size, shape, color, position, symmetry, and the presence of abnormalities like rashes or growths. You can help the physician perform the inspection by making sure good lighting is available and that the patient's body parts are properly exposed.

Auscultation

Auscultation is the process of listening to body sounds. Physicians use auscultation to detect the flow of blood through an artery and perform auscultation extensively in the general exam to assess sounds from the heart, lungs, and abdominal organs. They use a stethoscope to hear most of these sounds (see Figure 38-2).

Palpation

The physician uses **palpation** (touch) extensively in the general physical exam to assess characteristics such as texture, temperature, shape, and the presence of vibrations or movements. The physician may palpate superficially (on the skin surface), or she may palpate with additional pressure. She uses extra pressure when assessing characteristics of underlying tissues and organs. Depending on the characteristic the physician is measuring, she may perform palpation using the fingertips, one hand, two hands (bimanual), or the palm of the hand.

FIGURE 38-2 Auscultation, or listening to body sounds, can be done using a stethoscope.
© Jose Luis Pelaez/Blend Images LLC RF

Percussion

Percussion involves tapping or striking the body to hear sounds or feel vibrations. Physicians use percussion to determine the location, size, or density of a body structure or organ under the skin. For example, physicians use percussion to determine whether the lungs contain air or fluid.

The physician may perform percussion by striking the body directly with one or two fingers. More commonly, however, he performs indirect percussion by placing one finger of one hand on the area and striking it with a finger from the other hand.

Mensuration

Mensuration is the process of measuring. In addition to the measurements you take before the exam—weight and height—you may need to take other measurements during the exam. For example, measurements may be done to monitor the growth of the uterus during pregnancy or to note the length and diameter of an extremity or a wound. You will usually use a tape measure or small ruler to take measurements.

Manipulation

Manipulation is the systematic moving of a patient's body parts. Physicians may palpate an area of the body while manipulating it to check for abnormalities that affect movement. Physicians often use manipulation to determine a joint's range of motion (ROM).

► Components of a General Physical Exam

LO 38.8

Each physician performs the general physical exam in a certain order. Most physicians begin by assessing the patient's overall appearance and the condition of the patient's skin, nails, and hair. They usually then proceed with the exam in the following order, using the exam methods described in the previous section:

1. Head
2. Neck

3. Eyes
4. Ears
5. Nose and sinuses
6. Mouth and throat
7. Chest and lungs
8. Heart
9. Breasts
10. Abdomen
11. Genitalia
12. Rectum
13. Musculoskeletal system
14. Neurologic system

Learn the standard order that licensed practitioners in your facility follow when performing the general exam. You also should be familiar with the components of the exam and the instruments and supplies needed for each component (see Table 38-2 and Figure 38-3).

The following are the basic items needed for a general physical exam:

- Penlight
- Otoscope/ophthalmoscope
- Vision chart
- Color vision chart

TABLE 38-2 Components and Materials for a General Physical Exam

Component	Materials Required*
General appearance (skin, nails, hair)	No special materials needed
Head	No special materials needed
Neck	No special materials needed
Eyes and vision	Penlight, ophthalmoscope, and vision and color vision charts
Ears and hearing	Otoscope and audiometer
Nose and sinuses	Penlight and nasal speculum
Mouth and throat	Gloves and tongue depressor
Chest and lungs	Stethoscope
Heart	Stethoscope
Breasts	No special materials needed
Abdomen	Stethoscope
Genitalia (women)	Gloves, vaginal speculum, and lubricant
Genitalia (men)	Gloves
Rectum	Gloves and lubricant
Musculoskeletal system	Tape measure
Neurologic system	Reflex hammer and penlight

*Gloves should always be worn if your hands will come in contact with the patient's nonintact skin, blood, body fluids, or moist surfaces. Additional appropriate PPE should be worn when patients have a suspected or actual infectious disease.

FIGURE 38-3 Some common instruments and supplies for the general physical examination are (A) color vision chart, (B) ophthalmoscope, (C) otoscope, (D) tongue blades (depressors), (E) near vision chart, (F) penlight, (G) vaginal speculum, (H) gloves, (I) lubricant, and (J) stethoscope.
© Total Care Programming, Inc.

- Audiometer
- Nasal speculum
- Gloves
- Tongue depressor
- Stethoscope
- Vaginal speculum (for female internal exam only)
- Lubricant (for rectal exam)
- Tape measure

Certain parts of the exam may be your responsibility and you should know how to perform them. You also should understand the physician's responsibilities. Part of the medical assistant's role in the general exam is to ensure the patient is as comfortable as possible. You can do this by helping to protect the patient's modesty as much as you can. For example, when the physician removes a drape or gown to expose an area for inspection, watch the patient for signs of embarrassment. If you notice any such signs, do your best to keep the patient covered without hindering the physician's exam. The steps for assisting the physician with a general physical exam are outlined in Procedure 38-4 at the end of this chapter.

General Appearance

The physician usually begins the exam by reviewing the patient's general appearance and noting whether the patient appears to be in good health and of an acceptable weight. The physician also notes whether the patient appears to be

distressed or in pain and assesses the level of the patient's alertness. Then the physician examines the patient's skin, nails, and hair.

Skin The physician may prefer to examine all of the patient's skin at one time or to look at certain areas of skin while examining specific body parts. The physician notes the skin's color, texture, moisture level, temperature, and elasticity. The condition of the skin is a good indicator of overall health. If the physician notices any lesions, he wears gloves to prevent possible transmission of microorganisms. The physician also may request that a specimen be taken from a lesion or wound for later examination to determine the infecting microorganism.

Nails When the physician examines the patient's nails, he looks at both the nails and the nail beds. The condition of the nails may indicate poor nutrition, disease, infection, or injury. If needed, remind the patient to remove nail cosmetics prior to the appointment.

Hair The physician notes the patient's pattern of hair growth and the texture of the hair on the patient's scalp and on the rest of the body. Sudden hair loss or changes in hair growth may be indicators of an underlying disease.

Head

After reviewing the patient's general appearance, the physician examines the patient's head. He looks for any abnormal condition of the scalp or skin, puffiness around the eyes or lips or in other areas of the face, or any abnormal growths.

Neck

The physician checks the neck for symmetry and range of motion. He also palpates the neck to check the patient's lymph nodes, thyroid gland, and major blood vessels. Enlarged lymph nodes may be a sign of infection or blood cancer.

Eyes

The physician examines the patient's eyes—particularly the eyelids and conjunctiva—for the presence of disease or abnormalities. He checks eye muscles by observing the patient's ability to follow the movement of a finger. He checks the pupils for their response to light (the pupils should constrict—become smaller—when a penlight is directed toward them). Then he uses an ophthalmoscope to examine the patient's retinas and other internal structures of the eyes. You may be required to perform various vision tests either before or after the general physical exam.

Ears

The physician checks the patient's outer ears for size, symmetry, and the presence of lesions, redness, or swelling. Using an otoscope, he then examines the inner structures of the patient's ears. The physician may ask you to assist in keeping the patient's head still during the otoscopic exam, particularly if the patient is a young child. Although this procedure is usually painless, patients with an ear infection may find it uncomfortable or painful.

The physician checks the patient's ear canals for redness, drainage, lesions, foreign objects, or the presence of excessive cerumen (a waxy secretion from the ear, also known as earwax). During the most important part of the ear exam, the physician assesses the color, shape, and reflectiveness of the eardrums. If an eardrum bulges outward or reflects light abnormally, the middle ear could be infected. One of your responsibilities may be to perform various hearing tests either before or after the general physical exam.

Nose and Sinuses

When examining the nose, the physician checks for the presence of infection or allergy. She uses a penlight to view the color of the **nasal mucosa** (lining of the nose) and notes any discharge, lesions, obstructions, swelling, or inflammation. Mucosa that is red or swollen and is accompanied by a yellowish discharge usually indicates an infection. A pale, swollen mucosa accompanied by a clear discharge indicates an allergy. When examining adults, the physician uses the nasal speculum to view the structures of the nose.

The physician may use palpation to check for tenderness in a patient's sinuses. Tenderness is an indication of inflammation or swelling.

Mouth and Throat

The condition of the patient's mouth provides a general impression of overall health and hygiene. Using a tongue depressor to draw back the patient's cheeks, the physician examines the lining of the cheeks, the underside of the tongue, and the floor of the mouth. Changes in color or any lesions in these areas may indicate possible infection or oral cancer. The physician also assesses the condition of the teeth and gums. When examining children, he counts the number of teeth. Most physicians leave this part of the exam of infants and toddlers until last because children of this age tend to resist opening their mouths.

The physician also examines the patient's throat carefully, as it is a common site of infection. He uses a tongue depressor to press the patient's tongue down and out of the way while asking the patient to say "ah." This procedure allows the physician to view the throat and tonsils more clearly while checking them for redness or swelling, which can indicate the presence of infection.

Chest and Lungs

The physician usually assesses the patient's chest and lungs while the patient sits at the end of the examining table. The physician may remove the patient's gown or lower the drape from the waist up. Then he asks the patient to breathe normally or to take deep breaths. A patient who becomes dizzy during deep breathing may be hyperventilating. **Hyperventilation** is overly deep breathing that leads to a loss of carbon dioxide in the blood. You can help by having the patient breathe into a paper bag. If no bag is available, the patient can breathe into cupped hands.

The physician inspects the patient's chest from the back, side, and front. He checks its shape, symmetry, and postural position and looks for the presence of any type of deformity.

For example, **kypnosis**, better known as humpback, is commonly seen in the elderly.

The physician then uses a stethoscope to auscultate the chest from the back, side, and front. He listens to the lung sounds during both normal and deep breathing. The stethoscope allows him to hear abnormal breathing that may result from disorders such as bronchitis, asthma, or pneumonia. The physician also palpates the chest and performs percussion to check for the presence of fluid or a foreign mass in the lungs.

Heart

The physician usually examines the patient's heart and vascular system at the same time as, or immediately after, the lung exam. He may palpate the area first to locate the correct anatomical landmarks for placing the stethoscope. He may use percussion to check the heart's size. The patient should not speak while the physician auscultates the heart sounds with the stethoscope. The physician notes the heart's rate, rhythm, intensity, and pitch.

Breasts

During a general physical exam, every woman should have a complete breast exam to check for signs of cancer. The physician begins the exam with the patient in a sitting position. The physician asks the patient to hold her arms at her sides while he inspects the breasts for symmetry, contour, masses, and retracted areas. He then asks the patient to raise her arms above her head while he palpates the lymph nodes under her arms.

Next, the physician asks the patient to lie down and place her hand under her head on the first side to be examined. (The physician may ask you to place a small pillow or folded towel under the patient's shoulder blade on the same side.) This procedure allows the breast tissue to flatten evenly against the chest wall, permitting easier palpation. The physician then palpates the breast in a circular, systematic manner to check for lumps, examines the areola and nipple, and then repeats the procedure on the other side.

The breasts of men are also checked. When examining male patients, the physician palpates the patient's breasts and lymph nodes in the same manner that he does with his female patients. He also checks the breasts for lesions or swelling.

Abdomen

The physician examines the patient's abdomen while the patient is in a supine position with arms down at the sides. The abdominal muscles should be completely relaxed for this part of the exam. The physician may ask you to place a small pillow under the patient's head or knees (or both) to help keep the abdomen relaxed. If the patient is wearing a gown, it is raised to just under the breasts. If the patient is draped, the drape must be lowered to just above the genitalia to allow a complete view of the area. A separate drape should be placed to cover a female patient's breasts.

The order of exam methods for the abdomen should be followed correctly. The physician begins with inspection and auscultation, followed by percussion and palpation. Following this order allows the physician to listen to bowel sounds before palpating the abdominal organs. Palpation of the

abdominal area can change bowel sounds in such a way that the physician could misdiagnose a patient's condition.

The physician begins with an inspection of the abdominal skin's color and surface and follows with an inspection of the abdomen's shape and symmetry. He then uses auscultation to check bowel and vascular sounds and uses percussion to note the size and position of the organs. Finally, he uses palpation to check muscle tone and to determine the presence of any tenderness or masses.

The physician describes observations based on a system of landmarks that map out the abdominal region. The abdomen is typically divided into four equal sections, or **quadrants**. Some physicians divide the abdomen into nine sections, similar to a tic-tac-toe board. For example, if a patient has had her appendix removed, the physician might note that the patient has an abdominal scar on the right lower quadrant.

Female Genitalia

Female patients may feel self-conscious or anxious in the lithotomy position—most commonly used during examination of the genitalia. The medical assistant may help the patient relax during this procedure to assist the patient in maintaining the position. This type of exam may be performed by a specialist or by a primary care physician. The procedure for a gynecologic exam is described in detail in the *Assisting in Reproductive and Urinary Specialties* chapter.

Male Genitalia

During the genitalia exam, men may be just as embarrassed or uncomfortable as women. If the physician performing the assessment is female, a male medical assistant, if available, should be in the room to protect both the patient and the physician from potential lawsuits.

The procedure begins with the patient in the supine position. The physician puts on gloves and visually inspects the patient's penis for signs of infection or structural abnormalities, palpating any lesions. The physician then examines the scrotum in the same manner, palpating the testicles for lumps. The patient is asked to stand while the physician checks for any bulges in the groin that may indicate a hernia. At the same time, the physician palpates the local lymph nodes to check for any abnormality.

Rectum

The physician usually examines the rectum after examining the genitalia. You may need to assist an adult patient into a dorsal recumbent or Sims' position. Female patients may already be in the lithotomy position for this exam. The physician normally examines a child when the child is in the prone position and inspects only the external areas of the rectum.

In adults, the physician may perform a **digital examination** to palpate the rectum for lesions or irregularities. Physicians recommend that patients older than age 40 have a yearly digital examination for early detection of colorectal cancer. For this exam, the physician puts on a clean pair of gloves. You may assist by applying lubricant to the physician's gloved index finger before the exam begins.

After performing the procedure, the physician may request that any stool found on the glove be tested for the presence of

occult blood using a guaiac-based fecal occult blood test. The presence of occult blood in the stool is a possible indication of colorectal cancer or gastrointestinal bleeding. This test—often called by its brand name, Hemocult® or Seracult® test—involves placing a sample of stool on a cardboard slide. You assist by presenting the slide to the physician. To produce an accurate test, three consecutive bowel movements are tested; this sample is usually the first. After the exam, you may be responsible for instructing the patient on how to collect the additional two samples. The procedure is outlined on the package of the occult blood-testing kit and in the *Collecting, Processing, and Testing Urine and Stool Specimens* chapter.

After the rectal exam, offer the patient the opportunity to clean the anal area before you adjust the drape. Dispose of gloves and soiled materials in a biohazardous waste container.

Musculoskeletal System

If the physician did not examine the patient's back during the chest exam, he does so during the musculoskeletal assessment. The physician checks for good posture from the back and side. He may ask the patient to walk so he can assess her gait. The physician always asks a child to bend at the waist so that he can check for the presence of **scoliosis**, a lateral curvature of the spine.

During the musculoskeletal assessment, the physician determines range of motion, the strength of various muscle groups, and body measurements. The physician also examines the arms, hands, legs, and feet for any lesions, deformities, or circulatory problems.

The physician checks a patient's range of motion to detect joint deformities and to learn whether the patient has any limitations in movement caused by an injury or other conditions, such as arthritis. Checking a patient's range of motion also allows the physician to follow a patient's progress during recovery from an injury or surgery.

Neurologic System

The physician's neurologic assessment includes an evaluation of the patient's reflexes, mental and emotional status (including intelligence, speech, and behavior), and sensory and motor functions. The physician often performs the neurologic assessment at the same time as the musculoskeletal assessment because both systems are involved in movement and coordination.

The physician may incorporate certain aspects of the neurologic assessment into other parts of the exam. For example, testing how a patient's pupils react to light is part of an eye exam, but because this test also examines the patient's light reflex, the test includes a neurologic assessment as well. To check reflexes, the physician uses a reflex hammer to tap tendons in different areas of the patient's body.

Most exams of children also include an intellectual assessment, in which the physician asks the child general questions appropriate to the child's age. Physicians may also test the mental status and memory of older adults to detect disorders such as senility and Alzheimer's disease in patients who show signs of confusion or complain of memory loss.

► After the Exam

LO 38.9

After the physician completes the exam, you should assist in making the patient comfortable. Help her into a sitting position; then allow her to perform any necessary self-hygiene. Additionally, tests and procedures may be ordered. Depending upon what is ordered, you will complete them either before the patient dresses or after she is dressed. In addition, you may be responsible for patient education as well as follow-up care based on the physician's recommendations.

Additional Tests and Procedures

Post-exam procedures may include taking body fat measurements, obtaining blood samples, or preparing the patient for a diagnostic or therapeutic procedure, such as an X-ray or a physical therapy session. Other procedures medical assistants may perform before the patient dresses include administering cold or heat therapy, applying a bandage, collecting specimens, and administering certain medications.

If the physician has not ordered any additional procedures—or if wearing clothing does not interfere with the procedures ordered—the patient may dress. Help the patient get off the examining table and allow her to dress in privacy. Make sure she knows you are available to assist if she needs help dressing. Tests and procedures that can be done after the patient has dressed include urinalysis, pulmonary function tests, administration of oral medications, and eye or ear irrigation or medication administration.

Patient Education

The general physical exam provides you with the opportunity to assess the patient's educational needs. Based on the findings of the patient's interview, history, and exam, you may identify areas in which the patient will benefit from additional education.

Pay special attention to educating patients about risk factors for disease. For example, women are often instructed about the risk factors for breast cancer, and men are instructed about the risk factors for prostate cancer. The physician also may request that you teach patients how to administer certain

medications or how to perform self-help or diagnostic techniques. These procedures may involve collecting samples for occult blood testing or urine testing, applying cold or hot packs, or instilling eye drops. It is important to teach the patient the correct way to perform a diagnostic test. If a specimen is incorrectly obtained, the test results will be inaccurate.

Regardless of the type of instruction, be sure to address patients at a language level they can understand without talking down to them. To ensure they understand fully, ask patients to repeat each instruction and to perform each demonstration. Give patients written instructions they can refer to at home.

Follow-Up

After the exam, you must help the patient follow up on all of the physician's recommendations. Follow-up may include these actions:

- Scheduling the patient for future visits at the office
- Making outside appointments for certain diagnostic tests, such as mammograms or other radiologic procedures, or for therapeutic procedures, such as physical therapy
- Helping the patient and the patient's family plan for home nursing care after an illness or a surgical procedure
- Helping the patient obtain assistance from community or social service organizations, such as adult day care, counseling, or meal programs

Follow-up appointments can vary depending on the outcome of the patient visit. Patient follow-up can be scheduled to review diagnostic testing or laboratory results and to discuss possible treatment methods for any abnormal test results. Another type of follow-up visit is to monitor previous treatments for diagnosed conditions, such as hypertension or diabetes.

During the follow-up exam, it is important to make sure patient preparation is appropriate for the type of exam scheduled. For example, it is not necessary for a patient to disrobe for a follow-up exam for hypertension. Use your critical thinking skills and follow office procedures to prepare patients correctly for the various types of patient visits.

PROCEDURE 38-1 Positioning a Patient for an Exam

Procedure Goal: To effectively assist a patient in assuming the various positions used in a general physical exam

OSHA Guidelines:

Materials: Adjustable examining table or gynecologic table, stepstool, exam gown, and drape

Method:

1. Identify the patient and introduce yourself.
2. Wash your hands.
3. Explain the procedure to the patient.
4. Provide a gown or drape, if the physician has requested one, and instruct the patient in the proper way to wear it after disrobing. Allow the patient privacy while disrobing and assist only if the patient requests help.

RATIONALE: Taking an extra minute to explain to the patient how to wear the gown will make the visit more efficient and the patient more comfortable.

5. Explain to the patient the necessary exam and the position required.
6. Ask the patient to step on the stool or the pullout step of the examining table. If necessary, assist the patient onto the examining table.
7. Assist the patient into the required position:
 - a. *Sitting*. Do not use this position for patients who cannot sit unsupported.
 - b. *Supine (recumbent)*. Do not use this position for patients with back injuries, low back pain, or difficulty breathing. Place a pillow or other support under the head and knees for comfort, if needed.
 - c. *Dorsal recumbent*. This position may be difficult for someone with leg disabilities. It may be used for patients when lithotomy is difficult.
 - d. *Lithotomy*. This position is used to examine the female genitalia, with the patient's feet placed in stirrups. Assist as necessary. The patient's buttocks should be near the edge of the table. Drape the patient with a large drape to help prevent embarrassment.
 - e. *Fowler's*. Adjust the head of the table to the desired angle. Help the patient move toward the head of the table until the patient's buttocks meet the point at which the head of the table begins to incline upward.
 - f. *Prone*. In this position, the patient lies facedown. It is not used for later stages of pregnancy, obese patients, patients with respiratory difficulty, or certain elderly patients.
 - g. *Sims'*. In this position, the patient lies on her left side with her left leg slightly bent and her left arm behind her back. Her right knee is bent and raised toward her chest and her right arm is bent toward her head. This position may be difficult for patients with joint deformities.
 - h. *Knee-chest or knee-elbow*. This position is difficult for patients to assume. The patient is facedown, supporting his weight on his knees and chest, or in an alternative knee-elbow position. These positions are used for rectal and perineal exams. Keep the patient in this position for the shortest amount of time possible.

FIGURE Procedure 38-1 Step 7h Patient in the knee-chest position on examining table.

© McGraw-Hill Education

- i. *Proctologic*. This position also is used for rectal and perineal exams. In this position, the patient bends over the examining table with his chest resting on the table.

FIGURE Procedure 38-1 Step 7i Patient in the proctologic position.

© McGraw-Hill Education

8. Drape the patient to prevent exposure and avoid embarrassment. Place pillows for comfort as needed.
- RATIONALE:** The patient's comfort and safety are mandatory.
9. Adjust the drapes during the exam.
10. On completion of the exam, assist the patient out of the position as necessary and provide privacy as the patient dresses.

PROCEDURE 38-2 Communicating Effectively with Patients from Other Cultures and Meeting Their Needs for Privacy

Procedure Goal: To ensure effective communication with patients from other cultures while meeting their privacy needs

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissue.

Materials: Exam gown and drapes

Method:

Effective Communication

1. When it is necessary to use a translator, direct conversation or instruction to the translator.
RATIONALE: Translators will reduce the risk of litigation and improve patient outcomes.

FIGURE Procedure 38-2 Step 1 Medical assistant using a translator for effective communication with the patient.
© McGraw-Hill Education

2. Direct conversation and demonstrations of what to do, such as putting on an exam gown, to the patient.
3. Confirm with the translator that the patient has understood the instruction or demonstration.
4. Allow the translator to be present during the exam if the patient prefers.
5. If the patient understands some English, speak slowly, use simple language, and demonstrate instructions whenever possible.

Meeting the Need for Privacy

6. Before the procedure, thoroughly explain to the patient or translator the reason for disrobing. Indicate that you will allow the patient privacy and ample time to undress.

7. If the patient is reluctant, reassure him that the physician respects the need for privacy and will look at only what is necessary for the exam.

RATIONALE: Some patients from certain cultures are embarrassed when exposed.

FIGURE Procedure 38-2 Step 7 Medical assistant providing a gown to the patient.
© McGraw-Hill Education

8. Provide extra drapes if you think doing so will make the patient feel more comfortable.
9. If the patient is still reluctant, discuss the problem with the physician; the physician may be able to negotiate a compromise with the patient.
10. During the procedure, ensure that the patient is undraped only as much as necessary.
11. Whenever possible, minimize the amount of time the patient remains undraped.

PROCEDURE 38-3 Transferring a Patient in a Wheelchair for an Exam

Procedure Goal: To assist a patient in transferring from a wheelchair to the examining table safely and efficiently

OSHA Guidelines:

Materials: Adjustable examining table or gynecologic table, stepstool (optional), exam gown, and drape

Method: Caution: Never risk injuring yourself; call for assistance when in doubt. As a rule, you should not attempt to lift more than 35% of your body weight.

Preparation for Transfer

1. Identify the patient and introduce yourself.
2. Wash your hands.
3. Explain the procedure in detail.
4. Position the wheelchair at a right angle to the end of the examining table. This position reduces the distance between the wheelchair and the end of the examining table across which the patient must move.

5. Lock the wheels of the wheelchair.

RATIONALE: To prevent the wheelchair from moving during the transfer.

FIGURE Procedure 38-3 Step 5 Lock the wheels on the wheelchair before a transfer.
© McGraw-Hill Education

6. Lift the patient's feet and fold back the foot and leg supports of the wheelchair.
7. Place the patient's feet on the floor. The patient should have shoes or slippers with nonskid soles. Place your feet in front of the patient's feet.

RATIONALE: These actions prevent the patient from slipping.

8. If needed, place a stepstool in front of the table and place the patient's feet flat on the stool.

Transferring the Patient by Yourself

9. Face the patient, spread your feet apart, align your knees with the patient's knees, and bend your knees slightly.

RATIONALE: If you lift while bending at the waist instead of bending your knees, you can cause serious injury to your back.

10. Have the patient hold on to your shoulders.
11. Place your arms around the patient, under the patient's arms.
12. Tell the patient you will lift on the count of 3, and ask the patient to support as much of her own weight as possible (if she is able).
13. At the count of 3, lift the patient.

FIGURE Procedure 38-3 Step 13 Medical assistant transferring the patient by herself from wheelchair to exam table.

© McGraw-Hill Education

14. Pivot the patient to bring the back of the patient's knees against the table.
15. Gently lower the patient into a sitting position on the table. If the patient cannot sit unassisted, help her move into a supine position.
16. Move the wheelchair out of the way.

17. Assist the patient with disrobing as necessary, providing a gown and drape.

Transferring the Patient with Assistance

18. Working with your partner, both of you face the patient, spread your feet apart, position yourselves so that one of each of your knees is aligned with the patient's knees, and bend your knees slightly.

RATIONALE: If you lift while bending at your waist instead of bending your knees, you can cause serious injury to your back.

19. Have the patient place one hand on each of your shoulders and hold on.
20. Each of you places your outermost arm around the patient, one under each of the patient's arms. Then interlock your wrists.

FIGURE Procedure 38-3 Step 20 Interlock your wrists to lift the patient when transferring the patient with assistance.

© McGraw-Hill Education

21. Tell the patient you will lift on the count of 3, and ask the patient to support as much of her own weight as possible (if she is able).
22. At the count of 3, you should lift the patient together.
23. The stronger of the two of you should pivot the patient to bring the back of the patient's knees against the table.
24. Working together, gently lower the patient into a sitting position on the table. If the patient cannot sit unassisted, help her move into a supine position.
25. Move the wheelchair out of the way.
26. Assist the patient with disrobing as necessary, providing a gown and drape.

PROCEDURE 38-4 Assisting with a General Physical Exam **WORK // DOC**

Procedure Goal: To effectively assist the physician with a general physical exam

OSHA Guidelines:

Materials: Supplies and equipment will vary depending on the type and purpose of the exam and the physician's practice preferences. Supplies may include the following: patient chart/progress note, gown, drape, adjustable examining table, gloves, laryngeal mirror, lubricant, nasal speculum, otoscope and ophthalmoscope, pillow, reflex hammer, tuning fork, sphygmomanometer, stethoscope, tape measure, tongue depressors, and a penlight.

Method:

1. Wash your hands and adhere to standard precautions throughout the procedure.
RATIONALE: *Safe, aseptic technique greatly reduces the transmission of an infectious disease.*
2. Gather and assemble the equipment and supplies.
3. Arrange the instruments and equipment in a logical sequence for the physician's use.

FIGURE Procedure 38-4 Step 3 Assemble and arrange equipment for a general physical exam.

© McGraw-Hill Education

4. Greet and properly identify the patient using at least two patient identifiers.
RATIONALE: *To prevent treatment errors.*
5. Review the patient's medical history with the patient if office policy requires it.
6. Obtain vital statistics according to the physician's preference.
7. Obtain the patient's weight and height (with shoes removed).
8. Obtain a urine specimen before the patient undresses for the exam.
9. Explain the procedure and exam to the patient.
RATIONALE: *This builds the patient's confidence with the office and prepares the patient physically and emotionally.*
10. Obtain blood specimens or other laboratory tests according to the chart or verbal order.
11. Provide the patient with an appropriate gown and drape, and explain where the opening for the gown is placed.
12. Obtain the ECG if ordered by the physician.
13. Assist the patient to a sitting position at the end of the table with the drape placed across her legs.
14. Inform the physician the patient is ready and remain in the room to assist the physician.
15. You may be asked to shut off the light in the exam room to allow the patient's pupils to dilate sufficiently for a retinal exam.
16. Hand the instruments to the physician as requested.
17. Assist the patient to a supine position and drape her for an exam of the front of the body.
18. If a gynecologic exam is needed, assist and drape the patient in the lithotomy position.

FIGURE Procedure 38-4 Step 16 Hand the instruments to the physician as needed.

© McGraw-Hill Education

19. If a rectal exam is needed, assist and drape the patient in the Sims' position.
20. Assist the patient to a prone position for a posterior body exam.
21. When the exam is complete, assist the patient to a sitting position and ask the patient to sit for a brief period of time.
RATIONALE: *Some patients experience dizziness when they first sit up.*
22. Ask the patient if she needs assistance in dressing.
23. After the patient has left, dispose of contaminated materials in an appropriate container.
24. Remove the table paper and pillow covering and dispose of them in the proper container.
25. Disinfect and clean the counters and the examining table.
26. Sanitize and sterilize the instruments, if needed.
27. Prepare the room for the next patient by replacing the table paper, pillowcase, equipment, and supplies.
28. Document the procedure (refer to Progress Note).

LEARNING OUTCOMES	KEY POINTS
38.1 Identify the purpose of a general physical exam.	A general physical exam is done either to confirm an overall state of health or to examine a patient to diagnose a medical problem.
38.2 Describe the role of the medical assistant in a general physical exam.	The medical assistant assists the patient and the physician during an exam. Making the patient physically and emotionally comfortable as well as providing materials and assistance to the physician are essential to a successful exam.
38.3 Explain safety precautions used during a general physical exam.	During an exam, the medical assistant should perform hand hygiene, wear gloves and other personal protective equipment, ensure respiratory hygiene/cough etiquette, use isolation precautions, dispose of biohazardous waste, and clean and disinfect the exam room as necessary to provide for safety.
38.4 Carry out the steps necessary to prepare the patient for an exam.	The medical assistant should prepare the patient for an exam emotionally, by using simple direct language, and physically, by providing for the patient's comfort and privacy when positioning him or her according to the type of exam or procedure and by modifying techniques to meet the needs of special patients.
38.5 Carry out positioning and draping a patient in each of the nine common exam positions.	The nine common exam positions include sitting, supine, dorsal recumbent, lithotomy, Fowler's, prone, Sims', knee-chest/knee-elbow, and proctologic.
38.6 Apply techniques to assist patients from different cultures and patients with physical disabilities.	When assisting with the physical exam, avoid judging and stereotyping patients from different cultures and obtain a translator for proper communication if necessary. Assist patients who have physical disabilities with transfers and other tasks they cannot accomplish themselves.
38.7 Identify the six examination methods used in a general physical exam.	The six examination methods used in a general physical exam include inspection, auscultation, palpation, percussion, mensuration, and manipulation.
38.8 List the components of a general physical exam.	A general physical exam typically includes an evaluation of the general appearance, head, neck, eyes, ears, nose and sinuses, mouth and throat, chest and lungs, heart, breasts, abdomen, genitalia, rectum, musculoskeletal system, and neurologic system.
38.9 Describe follow-up steps after a general physical exam.	In order to assist the patient with follow-up after the exam, you may schedule future visits, schedule visits outside of the office, help plan for home care, and, if within your scope of practice, provide education related to the patient's condition.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall Valarie Ramirez from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. What would you chart as her chief complaint?
2. What things will you do during her exam to make her more comfortable?

3. What are the most likely position(s) she will be put in during her examination, and why would these positions be used?
4. If you were unable to communicate with Valarie successfully, what measures should you take to improve communication and meet her privacy needs?

EXAM PREPARATION QUESTIONS

1. (LO 38.7) When the physician uses a stethoscope to listen to body sounds, he is performing
 - a. Auscultation
 - b. Percussion
 - c. Inspection
 - d. Palpation
 - e. Mensuration
2. (LO 38.3) Which safety measure should the medical assistant perform with every patient?
 - a. Wear gloves
 - b. Use isolation precautions
 - c. Perform hand hygiene
 - d. Transfer the patient to the exam table
 - e. Place all waste in a biohazardous container
3. (LO 38.5) Which of the following positions would be used to examine the female genitalia?
 - a. Prone
 - b. Sims'
 - c. Fowler's
 - d. Proctologic
 - e. Lithotomy
4. (LO 38.1) The patient is complaining of pain in her left foot. This would be considered a
 - a. Sign
 - b. Symptom
 - c. Prognosis
 - d. Clinical diagnosis
 - e. Differential diagnosis
5. (LO 38.2) You are asked to do all of the following during a general physical exam. Which one is outside your scope of practice?
 - a. Prepare the instruments and supplies
 - b. Give the patient a pillow while the physician conducts the exam
 - c. Determine the vital signs, height, and weight
 - d. Provide the patient with emotional support
 - e. Check the patient's abdomen when he complains of pain
6. (LO 38.4) What would be your best response to a nervous, young female patient who is going to have a general physical exam by a male physician when she asks, "Will this hurt?"
 - a. An exam is not painful; you don't need to worry
 - b. No, you just have to lie still; I will be here with you the whole time
 - c. Yes, you can expect a lot of pain, but I will be here with you the whole time
 - d. You won't have any discomfort; Dr. Buckwalter is very gentle
 - e. The exam may be uncomfortable at times, but I will be here to help keep you comfortable
7. (LO 38.6) When assisting with a patient from another culture during an exam, which of the following would *least* likely be necessary?
 - a. Extra drapes
 - b. Translator
 - c. Wheelchair
 - d. Direct demonstrations
 - e. Thorough explanations
8. (LO 38.8) What is the purpose of a digital examination?
 - a. To check for blood in the urine
 - b. To determine if a female patient has breast cancer
 - c. To check for rectal lesions or irregularities
 - d. To locate a landmark on the abdomen
 - e. To listen to the patient's breathing
9. (LO 38.9) Which of the following would *not* be one of your duties after the physician has completed a general physical exam?
 - a. Schedule a future visit to check the blood pressure
 - b. Administer a medication
 - c. Provide patient education
 - d. Document a chief complaint
 - e. Help the family plan for in-home care

10. (LO 38.3) A patient is suspected of having TB. What PPE should you wear?
- Mask only
 - Mask and goggles when working within 3 feet of the patient
 - Gown and gloves
 - Gloves, gown, mask, and goggles
 - Mask and goggles or respirator

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Raja Lautu	2/23/19XX	Benzalkonium chloride
PATIENT INFORMATION	Attending	MRN	Other Information
	Elizabeth H. Williams, MD	224-86-564	Nonsmoker, occasional wine with meals

Raja Lautu, a 42-year-old woman, has arrived at the office for her annual gynecologic physical and the results of her annual digital mammogram. The digital mammogram results reveal a small, abnormal density close to the chest wall on the right breast. Dr. Williams speaks to Ms. Lautu and then schedules an ultrasound to determine if the density

© ERproductions Ltd/Blend Images LLC RF

is fluid-filled or solid. The right breast ultrasound reveals a solid mass close to the chest wall. Since the mass is solid, the physician orders a right stereotactic fine-needle breast biopsy, which reveals a grade II infiltrating ductal carcinoma (IDC).

Keep Raja Lautu in mind as you study the chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 39, you will be able to:

- 39.1** Carry out the role of the medical assistant in the medical specialty of gynecology.
- 39.2** Carry out the role of the medical assistant in the medical specialty of obstetrics.
- 39.3** Identify diagnostic and therapeutic procedures performed in obstetrics and gynecology.
- 39.4** Relate the role of medical assisting to the medical specialty of urology.
- 39.5** Identify diagnostic tests and procedures performed in urology.
- 39.6** Recognize diseases and disorders of the reproductive and urinary systems.

KEY TERMS

amenorrhea	menopause
dysmenorrhea	menorrhagia
induction	menstruation
infertility	metrorrhagia
last menstrual period (LMP)	postcoital
loop electrosurgical excision procedure (LEEP)	speculum
menarche	vasectomy
	wet mount

- I.C.6** Compare structure and function of the human body across the life span
- I.C.8** Identify common pathology related to each body system including:
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.9** Assist provider with a patient exam
- V.C.6** Define coaching a patient as it relates to:
 - (e) adaptations relevant to individual patient needs
- X.P.3** Document patient care accurately in the medical record

- 2. Anatomy and Physiology**
 - a. List all body systems, their structure and functions
 - b. Describe common diseases, symptoms and etiologies as they apply to each system
 - c. Identify diagnostic and treatment modalities as they relate to each body system
- 3. Medical Terminology**
 - c. Apply various medical terms for each specialty
- 4. Medical Law and Ethics**
 - a. Follow documentation guidelines
- 9. Clinical Procedures**
 - d. Assist provider with specialty examination including cardiac, respiratory, OB-GYN, neurological, gastroenterology procedures
 - e. Perform specialty procedures including but not limited to minor surgery, cardiac, respiratory, OB-GYN, neurological, gastroenterology
 - g. Recognize and respond to medical office emergencies
 - h. Teach self-examination, disease management and health promotion
 - j. Make adaptations with patients with special needs
- 10. Medical Laboratory Procedures**
 - b. Perform selected CLIA-waived tests that assist with diagnosis and treatment
 - (6) Kit testing
 - (a) Pregnancy

► Introduction

Obstetrics (OB) involves the study of pregnancy, labor, delivery, and the period following labor, called postpartum. This field is often combined with gynecology (GYN), which is care of the female reproductive system. An OB/GYN practices both specialties. A urologist diagnoses and treats disorders and diseases of both the female and the male urinary systems, as well as the male reproductive system. For this reason, the specialty fields of OB/GYN and urology are discussed together in this chapter. Excellent knowledge of the reproductive and urinary systems (both male and female) is a must to work in these specialties. As a medical assistant, you will need to recall diseases and disorders, examinations, diagnostic tests, and treatments for each of these systems. Most importantly, you must be able to assist the physician, physician assistant, nurse practitioner, midwife, or other licensed practitioner during exams, treatments, and procedures and be able to provide patient education unique to these specialties.

► Assisting with the Gynecologic Patient

LO 39.1

Gynecologic patients are females, and as females mature, they experience many physical changes throughout their bodies. These changes, including menstruation and menopause and the hormones that cause them, are common reasons for women to visit their OB/GYN licensed practitioner.

Menstruation

Menstruation is a woman's normal cycle of preparation for conception (the union of egg and sperm that initiates pregnancy). The normal age range of **menarche**—the beginning of menstruation—is 10 to 15 years of age. Each month (averaging every 28 days), the endometrium, which lines the uterus, is shed in vaginal bleeding. If the woman becomes pregnant, this shedding does not occur and the woman misses her menstrual period.

A period lasts an average of 5 days, with durations of 3 to 7 days considered normal. Menstrual cycles are prompted by changes in hormonal (estrogen and progesterone) levels.

Menopause

Menopause, like menstruation, is a natural occurrence. It is the cessation (the end) of the menstrual cycle. Menopause usually occurs between ages 45 and 55. Several stages surround menopause. Premenopause is the time period before menopause, during which the menstrual periods may be irregular. The time just before and after menopause is called perimenopause. During perimenopause, a woman may experience irregular periods, hot flashes, and vaginal dryness, all caused by changing levels of estrogen. Because hormonal change is occurring, the woman may experience mood swings or other psychological changes. Menopause can also be brought on by the surgical removal of the uterus and ovaries, known as a hysterectomy and discussed later in this chapter. The symptoms and treatment for menopause are the same for both surgical and naturally occurring menopause.

The Gynecologic Exam

The gynecologic exam is intended to provide an overview of a woman's health and to offer the opportunity for important cancer-screening exams and tests. The American College of Obstetricians and Gynecologists (ACOG) has specific recommendations regarding when a woman should have a gynecologic exam and tests related to the female reproductive system. These recommendations are outlined in Table 39-1.

During the exam, a female medical assistant should be in the exam room to assist a male licensed practitioner. In this case, the medical assistant can act as a witness to provide legal protection. Your role during the exam is similar to that for the general physical exam. In this role, you will complete the following:

- Ask the patient to empty her bladder; if a urine specimen is needed, it should be collected at this time.
- Provide the patient with a gown before the exam and give her privacy while she changes.
- During the interview, discuss her gynecologic and general health and inquire about any changes in appetite, weight, or emotional status.
- Observe for signs of problems such as substance abuse, sexually transmitted infections, or domestic violence. It is crucial that you bring to the licensed practitioner's attention any clues you notice during your interview. See the *Caution: Handle with Care* feature Detecting Domestic Violence.
- Determine the first day of her **last menstrual period (LMP)**.
- Then have her sit on the examining table while you check her vital signs. For accurate results, keep the patient's arm elevated during the blood pressure measurement. For example, you may have her rest her arm on your shoulder.

The Licensed Practitioner's Interview

The gynecologic physical exam is more than an internal pelvic exam. It is an evaluation of the patient's total health and a review of factors that could be an indication of possible cancer or sexually transmitted infections (STIs). STIs, previously known as STDs (sexually transmitted diseases), are discussed later in this chapter. The licensed practitioner asks questions about the patient's menstrual cycle and about any abnormal discharge or discomfort during sexual intercourse. These questions help the licensed practitioner determine what tests need to be ordered. The licensed practitioner also examines the breasts and listens to the patient's heart and lungs before beginning the gynecologic exam.

Breast Exam

While reviewing the patient's chart, the licensed practitioner checks to see when the last mammogram was performed. He will also ask the patient about any other concerns or changes in her breasts. Since the breast self-exam is now an optional screening tool for breast cancer, the physician may or may not ask whether she knows how to perform a breast self-exam (BSE) and how often she is performing this exam. The licensed practitioner will then perform a clinical breast exam (CBE) by examining the patient's breasts and underarm areas to check for abnormal lumps that could be cancerous.

Patients must understand the need for regular breast exams including mammograms (discussed later in this chapter), clinical breast exams, optional breast self-exams, and additional tests if needed. When interviewing the patient and after the exam, you should take a moment to emphasize the following breast cancer detection guidelines of the American Cancer Society and National Cancer Institute:

- Yearly mammograms are recommended starting at age 40 and continuing for as long as a woman is in good health.
- A clinical breast exam is recommended about every 3 years for women in their 20s and 30s and every year for women 40 and over.

Age	Exam(s) Needed	Frequency
<21	Cervical cytology	Three years after onset of sexual activity, then annually
	Pelvic exam	As medical history dictates
21–29	Pelvic exam and cervical cytology	Annually
<25	Chlamydia screening	When sexually active
Adolescents	Gonorrhea screening	When sexually active (can use urine-based screening)
19–64	HIV screening	When sexually active
30–64	Pelvic exam and cervical cytology	Annually; under certain conditions, decrease to every 2 to 3 years after 3 normal tests
>65	Pelvic exam	Annually
	Cervical cytology	Discontinue after 3 normal tests under certain conditions

CAUTION: HANDLE WITH CARE

Detecting Domestic Violence

Licensed practitioners and medical assistants are in a position to detect signs of domestic violence. These signs can be seen in unusual bruising or injuries that the patient may try to hide or excuse. You may hear signs in a patient's tone of voice or choice of words during a conversation in the office or over the telephone. Many times patients who are abused blame themselves. When the patient's injuries do not match his or her story, this may indicate the likelihood of abuse. Observe the male or female who constantly answers questions for his or her partner. You play an important role in noticing these signs, and you must inform the licensed practitioner of any signs that you detect.

You must also create a supportive office environment where the patient can seek help. Encourage the licensed practitioner to join the American Medical Association's National Coalition

of Physicians Against Family Violence if not already a member. This organization provides posters—which often help patients feel encouraged to discuss domestic violence—in addition to pamphlets and other information. Reporting suspected domestic violence is mandatory in some states. You should have a folder that contains lists of the phone numbers for domestic violence hotlines, women's shelters, and other helpful resources. You can offer the following general guidelines to women.

- Ignoring the problem never works—silence does not help anyone.
- Understand that abusive family members may not be able to help themselves.
- Call for help if a physical threat exists.

- Women should know how their breasts normally look and feel and report any breast change promptly to their health-care provider. A breast self-exam is an option for women starting in their 20s.
- Women with a family history, a genetic tendency, or certain other factors should be screened with an MRI (discussed later in the chapter) in addition to mammograms. The number of women who fall into this category is less than 2% of all the women in the United States.

In some cases, you may be asked to instruct the patient in performing the BSE. Review the *Educating the Patient* feature How to Perform a Breast Self-Exam.

Pelvic Exam

During the pelvic exam, the licensed practitioner checks the external genitalia, cervix, vaginal wall, internal reproductive

organs, and rectum. Exam methods include palpation and inspection. Inspection is done with a **speculum**, which is an instrument that expands the vaginal opening to permit viewing of the vagina and cervix (see Figure 39-1). The licensed practitioner wears gloves and may use a lubricant for patient comfort.

Your role is to assist the patient into position, with her feet in the stirrups of the examining table and her buttocks at the end of the table. Drape her so that only the area between the thighs is exposed. Assist the licensed practitioner by having gloves and instruments ready for use and by applying lubricant, if indicated, to the licensed practitioner's gloved fingers.

You also may warm the speculum for the patient's comfort. Be prepared to provide reassurance and explanation to a patient who appears to be uncomfortable or nervous. Encourage her to breathe deeply to help relax the pelvic muscles and reduce discomfort. After checking the vagina and cervix and while the speculum is still in place, the licensed practitioner

EDUCATING THE PATIENT

How to Perform a Breast Self-Exam

The breast self-exam, although now considered an optional screening method for breast cancer, is still an important part of breast cancer prevention. As a medical assistant, you may be responsible for coaching the patient about the monthly breast self-exam. Check the office policy to see which of several methods it recommends for teaching BSE.

Consider the following when teaching the BSE:

1. Explain the purpose of the BSE. Make sure the patient knows that she should perform the BSE around the same date of each month after her period ends, if she is still menstruating. (At this time, the breasts are most normal and least swollen and lumpy.) Have the patient mark her calendar as a monthly reminder.
2. Emphasize that the BSE is not a substitute for mammograms or regular breast exams by a licensed practitioner.
3. Demonstrate the breast self-exam according to the method used at your facility. For example, the National Cancer Institute has established one method and provides the instructions on its Internet site.
4. Observe the patient's self-exam technique. (If the patient is reluctant to examine herself in front of you, have her repeat the highlights of the procedure or use the synthetic model.)
5. Review and reinforce teaching as needed. Provide patient educational materials that explain how to perform the BSE.

FIGURE 39-1 A speculum is used to expand the vaginal opening to help view the vagina and cervix and obtain specimens.

obtains a specimen. The most common type of specimen the licensed practitioner will obtain is a Papanicolaou (Pap) smear. This test is discussed later in the chapter.

Sometimes a sample is taken by the licensed practitioner to test for infections. These specimens are usually prepared by the medical assistant during the procedure and viewed by the licensed practitioner after the exam. To check for fungus, a sample may be mixed with potassium hydroxide (KOH) on a slide. The slide is viewed under a microscope. The KOH helps dissolve the cells and mucus in the sample so that the fungus can be better visualized. A **wet mount** is prepared by mixing a sample with a saline solution. The slide is viewed to check for bacteria, yeast, and trichomoniasis. Trichomoniasis, commonly called “trich,” is a vaginal infection caused by a microscopic organism and is transferred during sexual intercourse.

The licensed practitioner then removes the speculum and begins the bimanual phase of the exam. *Bimanual* means using two hands rather than the speculum. The practitioner may ask for your assistance in removing the examining

gloves, putting on new gloves, and lubricating two fingers. Placing those fingers in the vagina and using the other hand to palpate the abdomen, the licensed practitioner assesses the position of the uterus. She may then place a lubricated finger in the rectum and palpate for abnormal growths with the other hand by pressing on the lower abdomen.

When the licensed practitioner completes the exam, she usually asks the patient if she has any questions or concerns. After the licensed practitioner leaves the exam room, be sure to ask the patient whether she has additional questions. You may need to provide written information in addition to answering the patient’s questions orally. Materials are available from a variety of sources, including the AMA, government agencies, and pharmaceutical companies. The website of the National Women’s Health Information Center is one excellent resource. See Procedure 39-1, at the end of this chapter, on how to assist with a gynecologic exam. The *Caution: Handle with Care* feature Guidelines for Cervical Specimen Collection and Submission provides information about how to ensure an adequate specimen for optimal screening.

▶ Assisting with the Obstetric Patient

LO 39.2

When a woman discovers she is pregnant, one of the first things she wants to know is the baby’s due date. One simple method to estimate the delivery date for a pregnant woman is called Nägele’s rule. Begin with the first day of the patient’s last menstrual period, subtract 3 months, and add 7 days plus

CAUTION: HANDLE WITH CARE

Guidelines for Cervical Specimen Collection and Submission

In order to ensure that the cervical specimen collected is adequate for optimal screening, the American Society of Cytopathology has clinical guidelines for collecting patient information. As a medical assistant, you will be responsible for helping the licensed practitioner implement these guidelines, which include

- Scheduling a patient appointment about 2 weeks after the patient’s last menstrual period.
- Instructing patients not to douche; use tampons, foams, or jellies; or have sexual intercourse 48 hours prior to the test.
- Completing a lab requisition form, which includes the following information:
 - Patient name (note any recent name changes)
 - Date of birth
 - Menstrual status (last menstrual period, hysterectomy, and so on)
 - Any patient risk factors
 - Specimen source
- Completing a specimen label, which includes the following materials and information:
 - Liquid samples
 - Complete all requested information on the label and affix it to the vial.
- Glass slide
 - Label the frosted end of the slide with the patient’s first and last name.
 - Include an additional patient identifier, such as the patient record number.

1 year. For example, if the first day of the last menstrual period was June 30, 2014, subtracting 3 months would give you March 30, 2014. After the addition of 7 days plus 1 year, April 6, 2015, would be the estimated delivery date.

Prenatal Care

Pregnant women should be attentive to nutrition, exercise, medical monitoring, and childbirth classes. They should avoid using tobacco, alcohol, and drugs. Normal changes occur during pregnancy, such as morning sickness (usually in the first trimester), weight gain, urinary frequency, fatigue, depression, constipation, and swollen hands and feet. Review Figure 39-2 and Table 39-2 regarding the trimesters of pregnancy and what changes may be expected.

You may perform or assist with routine tests for pregnant women, or you may send them to an outside laboratory.

These tests include the complete blood count (CBC), Rh-antibody determination, blood typing, Pap smear, urinalysis, and hematocrit, as well as tests for syphilis (rapid plasma reagin, or RPR), hepatitis B antibodies, HIV, and chlamydia.

Encouraging the obstetric patient to have regular checkups and to take proper care of herself may be part of your job. Prenatal visits become more frequent as the pregnancy progresses. Unless complications occur, a typical schedule for prenatal visits includes

- An initial prenatal visit.
- Monthly visits during the 2nd trimester.
- Visits every other week during the 3rd trimester up to 36 weeks' gestation.
- Once-a-week visits from 36 weeks until delivery.

FIGURE 39-2 The fetus develops over the course of three trimesters.

TABLE 39-2 Changes During Pregnancy

Stage of Pregnancy	Normal Changes	Example Complications
1st trimester (weeks 1 to 12)	Missed period, fatigue, morning sickness, frequent urination, moodiness, heartburn, constipation, swollen and tender breasts	Ectopic pregnancy—severe dizziness with vaginal bleeding and abdominal pain
2nd trimester (weeks 12 to 24)	Weight gain up to 4 pounds a month; fetal movement around 16 weeks; stretched, enlarging breasts; back, pelvis, and hip pain; mild contractions known as Braxton Hicks or “false labor”	Deep vein thrombosis—blood clot in a leg vein causing pain and swelling Preterm labor—painful uterine contractions that have a regular pattern and don’t go away with movement
3rd trimester (weeks 24 to 40)	Unable to sleep on back; leg cramps; frequent urination; strange dreams; nasal congestion; heartburn; constipation; hemorrhoids; varicose veins; puffiness, especially the feet	Pregnancy-induced hypertension—extreme swelling of the hands and face, headache, blurred vision

In addition to assisting with prenatal examinations, you may also help teach and support both parents throughout the pregnancy. You must document all information given to or taken from the patient. Providing information on the effects of using drugs or alcohol during pregnancy is particularly important. See the *Caution: Handle with Care* feature Alcohol and Drugs During Pregnancy.

The following are your responsibilities when assisting with routine prenatal patient visits:

- Ask the patient about any problems and record any symptoms she reports.
- Ask the patient to empty her bladder and obtain a urine specimen in the cup you provide.
- Weigh the patient and note her weight in the chart.
- Perform the reagent urine test (chemical analysis) and note the results in her chart.
- Give the patient a drape and ask her to undress from the waist down if the licensed practitioner will be performing an internal exam.
- Assist the patient to the examining table. Some positions (such as the prone—on the stomach—and lithotomy—on the back with the feet up—positions) are not recommended for a pregnant patient, especially during late stages of pregnancy. Other positions may be difficult or impossible for a pregnant woman to achieve.
- Take her vital signs. Record them in her chart.

- Assist the licensed practitioner as needed with the exam. Provide the flexible centimeter tape measure and Doppler, an instrument used to listen to the fetal heartbeat.
- Assist the patient from the examining table after the exam.

Procedure 39-2, at the end of this chapter, outlines steps to take that ensure that a pregnant woman’s needs are addressed during an exam.

Prenatal Care by the Licensed Practitioner

The licensed practitioner carefully monitors the progress of a pregnancy. She monitors the patient’s blood pressure, weight changes, and urinalysis results for possible signs of preeclampsia. Preeclampsia is a serious condition that can occur during pregnancy. Signs of this condition include increased blood pressure (hypertension), unusual weight gain because of edema, and protein in the urine. The licensed practitioner examines urine specimens for possible urinary tract infections (UTIs) and occasionally asks for other laboratory tests, such as a CBC. She may prescribe special vitamins and iron as dietary supplements.

During the prenatal period, the licensed practitioner will monitor for many conditions, including placenta previa, abruptio placenta, and gestational diabetes. Placenta previa is indicated by bright red vaginal bleeding that is painless. Abruptio placenta is a more serious condition that includes vaginal bleeding and back and abdominal pain. Gestational diabetes is indicated by an increase in glucose in the blood or urine.

CAUTION: HANDLE WITH CARE

Alcohol and Drugs During Pregnancy

Everything a pregnant woman eats, drinks, or smokes will affect her developing baby. Alcohol, for example, crosses the placental barrier and directly affects fetal development. Drinking alcohol during pregnancy can cause fetal alcohol syndrome (FAS). This syndrome may include fetal growth deficiencies, mental retardation or learning disabilities, heart defects, cleft palate, a small head, a small brain, and deformed limbs.

Preventing FAS by teaching all pregnant patients about the potential effects of alcohol on their unborn babies is crucial.

Drugs used during pregnancy can also pose problems for the unborn fetus. Whether the drugs are illegal, over-the-counter, or prescription, pregnant women should be aware of the potential effects. See the chapter *Principles of Pharmacology* for information about prescription drug pregnancy labeling.

Labor

When working in an OB/GYN office, you will need to know the signs of labor and when to tell the patient to go to the hospital. Most practices provide patient instructions regarding when to seek medical care and procedures to follow if they believe they are in labor. For example, most patients will be told to go to the hospital if they are having regular contractions—six or more per hour for at least 2 hours. Also, a sudden surge of fluid from the uterus indicates that the “water broke,” which signals impending labor and requires the patient to go to the delivering healthcare facility.

Delivery

Delivery of an infant is typically through the vagina. After the labor process and delivery, the licensed practitioner clamps, ties, and cuts the umbilical cord and presents the baby to the mother. Women either go into labor spontaneously or may need to have their labor induced. **Induction** of labor means that the patient is admitted to the delivering healthcare facility, then given medication to start uterine contractions. If labor is spontaneous, most women go to the delivering facility as directed by their licensed practitioner. However, the medical assistant may need to schedule inductions at the delivering healthcare facility.

If the pregnant woman cannot deliver the baby vaginally, the licensed practitioner may deliver the baby by performing an operation known as a cesarean section, or C-section. Several conditions may require a cesarean section, such as a large baby or a breech position. Again, the medical assistant may need to schedule C-sections with the delivering healthcare facility.

Deliveries can be an emergency. Although not a common occurrence or a typical job responsibility for a medical assistant, if you are working in a busy obstetric practice, knowing the steps of emergency childbirth may be appropriate. You could be called upon to assist a physician during an in-office emergency delivery.

Breastfeeding

Human milk is the preferred form of nutrition for an infant. Colostrum, the first milk the mother produces after delivery, is rich in antibodies that provide passive natural immunity to the baby. Breastfeeding is economical and convenient. There is no need to buy or make formula or wash bottles and nipples. Breast milk is always available to the baby at the correct temperature.

A woman's success at breastfeeding depends largely on her desire to breastfeed, her satisfaction with it, and her available support systems. You can support patients who choose to breastfeed by providing them with pamphlets and other written materials. Emphasize how essential the mother's nutritional intake is and explain that she needs to follow a high-protein, high-calorie diet. Patients who need help can be referred to lactation consultants or support groups such as the La Leche League.

Bottle Feeding

Bottle feeding is an acceptable alternative for women who choose not to breastfeed or for one reason or another are unable to breastfeed. There are several acceptable formulas available,

including milk-based, soy-based, and special formulas for low-birth-weight infants. The type of formula is recommended by the licensed practitioner. If an infant is to be bottle-fed, parents must be given instruction about the type of formula and how to prepare it correctly. Regular, full-fat cow's milk should not be given to a child until after his or her first birthday.

Postpartum

Postpartum is a period after the delivery of an infant. During this time women experience many changes and challenges as their body is trying to get back to normal. These include

- Shrinking of the uterus back to its prepregnancy size, which typically takes about 6 weeks.
- Sharp abdominal pains, known as afterpains, that occur while the uterus is shrinking. These usually subside about the third day.
- Sore muscles of the arms, neck, or jaw for women who have labored and/or delivered vaginally.
- Difficulty with urination and bowel movements.
- Postpartum bleeding (lochia), which may last up to 4 weeks and can come and go up to 2 months.
- Recovery from a vaginal tear, episiotomy (surgical incision for a vaginal delivery), or abdominal incision for C-section.
- Pain that may occur from pelvic bone separation during vaginal delivery.
- Emotional stress related to coping with the physical changes and the needs of the new family.

The postpartum patient returns to the licensed practitioner at least once after the delivery of her baby to be evaluated. As a medical assistant you will need to ask questions regarding her recovery and document any complaints or concerns. You also may need to assist with a physical exam or provide information about birth control if asked to do so by the physician. Recall methods of birth control from the chapter *The Reproductive Systems*.

► OB/GYN Diagnostic and Therapeutic Tests and Procedures

LO 39.3

Many OB/GYN offices have their own small laboratories for immediate results, especially for pregnancy-related tests. Other diagnostic tests and procedures are sent to outside laboratories or performed at outpatient surgery centers or hospitals.

Pregnancy Test

Pregnancy tests are done on a specimen of blood or urine (the patient's first urine of the morning). These tests detect whether or not the hormone human chorionic gonadotropin (HCG)—produced during pregnancy—is present. A variety of testing kits are available, including over-the-counter urine self-test kits that the patient can use at home. These tests are not foolproof; false positives and false negatives do occur. For example, an abnormal pregnancy can result in a lower level of HCG that is not detectable by the tests. Urine specimens that contain blood, protein,

or drugs also can give a false-positive result. False negatives may result from testing too early after getting pregnant or from a urine specimen that is too dilute. Dilute urine occurs when the woman has consumed too much fluid and the urine does not have enough HCG to cause the test to react as a positive. The tests are also subject to human error. The licensed practitioner confirms pregnancy after taking the patient's history, performing an exam, and ordering a pregnancy test. You can review and practice this procedure, presented in the *Collecting, Processing, and Testing Urine and Stool Specimens* chapter.

Tests for Sexually Transmitted Infections

The licensed practitioner diagnoses and treats sexually transmitted infections (STIs) by taking bacterial and tissue cultures, examining lesions, ordering blood tests, and discussing the patient's history, as appropriate for the specific disease. Some facilities do not permit the release of these results, even to the parents of a minor, without the patient's written consent. Be sure you are familiar with your state's regulations regarding the reporting of STIs to the state epidemiology department.

Radiologic Tests

Several radiologic tests are used in obstetrics and gynecology. The gynecologist uses X-ray, ultrasonography, CT scan, and MRI. X-rays are avoided when a patient is pregnant. If it is crucial for a pregnant woman to have an X-ray, a lead apron must cover her abdomen, and she must be made aware that the X-ray could cause an abnormality in the fetus. As a medical assistant, you will usually schedule the appointment for radiologic tests. Tell the patient when and where to go for the test and answer her questions about the procedure. Medical assistants need further training to assist with X-ray procedures.

Hysterosalpingography Hysterosalpingography is an X-ray exam of the fallopian or uterine tubes and the uterus that uses a contrast medium, such as dye or air. Because the procedure is quite uncomfortable, the licensed practitioner may prescribe a sedative.

Mammogram A mammogram is a picture of the breast on film or digital media. Digital mammograms are more easily stored and transported and require less radiation. Mammography can detect cancer about 2 years before it can be palpated with a BSE. A baseline or first mammogram is done so that later mammograms can be compared. The mammogram procedure involves compressing the breast to obtain a clear X-ray (Figure 39-3). Recall our patient Raja Lautu, whose routine mammogram revealed an abnormality that was later found to be cancerous. Detailed information may need to be discussed with the patient before she has a mammogram. Review the *Educating the Patient* feature Checking for Breast Cancer to help you prepare the patient for a mammogram.

FIGURE 39-3 Mammography consists of two views of each breast and is achieved by compressing the breast between the radiography plates.

Fetal Screening

Fetal screening tests can indicate the presence of several types of birth defects, including Down syndrome and spina bifida. The licensed practitioner will consider the patient's age and medical history and the age of the unborn baby when ordering fetal screening tests. Tests for determining the health of an unborn child are performed on many women. Some, like an ultrasound, may be performed routinely. Other tests are used only for women whose unborn babies are at high risk of having birth defects. This includes women over 35, couples with a family history of genetic defects, and couples who have had a previous child with a birth defect.

Alpha Fetoprotein Alpha fetoprotein (AFP) is a protein produced by the unborn child that normally passes into the mother's blood. A blood test determines whether the AFP level in the blood is normal. Too little or too much AFP in the blood can indicate a fetal abnormality known as a neural tube defect. A neural tube defect is a developmental abnormality of the brain or spinal cord. AFP is also measured in amniotic fluid collected by amniocentesis. The licensed practitioner may order a blood test known as a triple screen or triple test. In addition to AFP, maternal levels of human chorionic

EDUCATING THE PATIENT

Checking for Breast Cancer

A mammogram may be ordered if a licensed practitioner detects a suspicious lump in a patient's breast or as part of the yearly screening. In either case, you should remain calm when preparing the patient for her first mammogram.

Preparing the Patient for a Mammogram

To alleviate some of the patient's fears, explain exactly what a mammogram is. Provide the patient with the following information:

1. A mammogram is a special type of X-ray of the breast that is used to detect cancer and other breast abnormalities.
2. A technician specially trained in performing mammography will position the patient's breast along a flat, plastic plate. A second plate will be brought into position and pressure will be applied for about 20 to 30 seconds to flatten the breast (to obtain a clearer X-ray) while the X-ray is taken. This will be done in two directions (planes) for each breast.
3. Mammography is generally not a painful procedure, but some women may find it uncomfortable. Many professionals suggest that patients avoid scheduling a mammogram during the week prior to a menstrual period to reduce potential discomfort.
4. The mammography appointment normally takes half an hour to an hour. The actual mammography takes only about 15 minutes.
5. Because the patient will have to undress from the waist up, she should wear a separate top and slacks or a skirt rather than a dress.
6. The patient should have no creams, powders, or deodorants on her breasts or underarms when the mammography is performed because chemicals in these preparations can produce misleading images in the mammogram.
7. If the patient has films from previous mammograms, it is important for the radiologist to see the films for a comparison study. If you schedule a mammogram, make sure you instruct the patient to obtain previous mammogram films prior to the screening if the films are located in a facility other than the one scheduled.

In addition, it is important in your role as a medical assistant during this procedure to answer any questions the patient has and to provide patient education materials related to mammography and breast disease. If your office refers patients to a particular facility that you are familiar with, give the patient an idea of how long she can expect to wait for the results. Assure her that she will be notified as soon as the licensed practitioner receives the report. You may want to schedule a follow-up visit at this time, based on when results are expected. Tell the patient that if she has any questions at all, she should call the licensed practitioner.

gonadotropin and estriol are tested. These substances, like AFP, are only present during pregnancy. The triple test is used to detect neural tube defects and is a better indicator of Down syndrome than AFP alone. This test is generally done between the 15th and 22nd weeks of pregnancy.

Ultrasound Ultrasound translates the echoes of sound waves into a picture of an internal part of the body. The picture, or image, is called a sonogram, and it can help identify and diagnose cysts and tumors in the abdominal cavity or obstructions of the urinary tract. Ultrasound is painless and safe to use on pregnant women to determine fetal size and position. It is also used to guide a licensed practitioner in performing amniocentesis as well as chorionic villus sampling (CVS) for chromosomal abnormalities and other inherited disorders. A patient who is going to have an ultrasound exam during early pregnancy should be instructed not to urinate before the test because a full bladder allows a better view of the uterus. The patient is asked to lie on an examining table and a gel or lotion is applied to the surface of her skin on the abdomen. This gel or lotion helps enhance sound wave conduction and reduce friction of the transducer on the skin (Figure 39-4).

Invasive Procedures

Many surgical OB/GYN procedures require the use of needles or other instruments to obtain tissue or amniotic fluid samples. Some procedures are used for obstetric reasons only; others may be used gynecologically and obstetrically.

Pap Smear A Pap smear is used to determine the presence of abnormal or precancerous cells. As discussed earlier, during a pelvic exam, cells from the cervix, endocervix, and vagina are smeared on a special, properly labeled slide. They are then sprayed with a fixative and sent to a laboratory for microscopic analysis. Obtaining accurate Pap smear results is an important tool in the successful treatment of cervical cancer. See the *Points on Practice* feature Pap Smear Technologies. The Pap test results are classified according to level of abnormality. The Bethesda system is used for interpreting the results. Review Table 39-3 to better understand Pap smear results.

Amniocentesis Amniocentesis is a procedure performed when a genetic or metabolic defect is suspected in a fetus. The test involves removing from the uterus a small amount of amniotic fluid, which surrounds the fetus. The licensed practitioner inserts a needle, which is guided with ultrasonography,

(a)

(b)

FIGURE 39-4 (a) An ultrasound technician lightly rubs the transducer over a pregnant woman's abdomen to reveal the anatomy of her fetus. (b) Routine ultrasounds are usually two-dimensional, as shown here; however, three-dimensional ultrasounds can be done.

POINTS ON PRACTICE

Pap Smear Technologies

During a Pap smear, a false-negative test occurs when abnormal cells are not detected. This can occur as a result of the following:

- Too many cells left on the sampling device (brush, broom, or spatula)
- Too many cells piled on top of one another on the slide
- Epithelial cells hidden by extraneous material (blood, mucus, and so on)

A false-negative result could cause a delay in treatment of a year or more, depending on the timing of the next Pap smear. Different types of tests have been developed to help reduce false negatives. The thin-layer preparation of cells is a liquid-based sampling technique. The licensed practitioner collects cervical cells in much the same way as for traditional Pap smears, using a brush- or broom-like device. Once collected, the cells are suspended in a liquid preserving medium rather than being smeared directly onto a glass slide. The cells are then sent to an outside laboratory, where they are filtered or centrifuged and placed on a slide in a thin layer. This method

has been shown to produce samples that are more accurately interpreted by cytotechnologists. A cytotechnologist is a healthcare professional who uses a microscope to examine cells for changes that might indicate the presence of cancer. The advantages of thin-layer preparation over conventional specimen preparation include the following:

- Artifacts caused by air-drying are reduced because cells are placed in a fixative solution immediately.
- The possibility of hidden cells is reduced because cells are placed on the slide in a single layer.
- Blood and cellular debris are removed from the field of view because they are washed away or filtered out.
- The fluid left over after the thin-layer slide preparation may be used for additional testing (for instance, DNA testing for human papillomavirus).

If your office uses a thin-layer cell preparation system, make sure you read and follow all instructions for handling specimens. These instructions can be found in the package inserts for the individual tests.

TABLE 39-3 Understanding Pap Smear Results*

Classification	What It Means	Tests and Treatments That May Be Indicated
Unsatisfactory	Inadequate sampling or other interfering substance	The test must be repeated.
Negative	Cells appear normal and no identifiable infection is evident.	Continue routine Pap smears.
Benign	Noncancerous cells, but smear shows infection, irritation, or normal cell repair.	Continue routine Pap smears.
Atypical cells of uncertain significance: either ASC-US or ASC-H	Abnormal cells are present but it is uncertain what these cells may indicate.	Repeat the Pap smear; sometimes changes can go away without treatment. Estrogen cream for women who are at or near menopause. Follow-up test of cells for presence of high-risk HPV (human papillomavirus). If HPV is present, a colposcopy is performed.
Low-grade changes (mild dysplasia)	Cells have changes that are not cancer but have the potential to be cancer. Cell changes may be caused by HPV infection.	HPV testing; repeat Pap test; colposcopy, and if abnormal tissue is found, then endocervical curettage or biopsy
High-grade changes (moderate to severe dysplasia or carcinoma in situ, depending upon amount and location of cells)	Cells have more evident changes and look very different than normal cells.	Colposcopy and biopsy; LEEP procedure, cryotherapy, laser therapy, or conization
Squamous cell carcinoma	Cells invade deep into the cervix and other tissues or organs.	Immediate treatment including surgical removal; rare finding in well-screened populations such as the United States

*Based on the Bethesda System for Classification of Papanicolaou Smear.

through the anesthetized lower abdominal wall. Fetal skin cells obtained from the fluid are then grown in a culture and examined for chromosomal abnormalities. The level of AFP also may be measured in amniotic fluid.

Chorionic Villus Sampling Chorionic villus sampling (CVS) is a test done on patients over 35 or those with a history of genetic disorders to determine problems with the fetus. A sample of the chorionic villi (finger-shaped projections) of the placenta is collected either through amniocentesis or directly through the vagina. Collection through the vagina and cervix is done by using a small flexible tube with a long thin needle. As in amniocentesis, an ultrasound is used as a guide to locate the correct spot for sampling. Unlike amniocentesis, which is usually done between 15 and 20 weeks, a sampling can be taken through the vagina as early as 10 to 12 weeks. This provides parents the results earlier in the pregnancy so a decision can be made whether to continue or end the pregnancy.

Biopsy Biopsy is the surgical removal of tissue for later microscopic exam. It is the most accurate and, in some cases, the only way to diagnose breast and other cancers. Biopsy of the endometrium, which is the mucous membrane lining the uterus, may help the licensed practitioner diagnose uterine cancer and show whether ovulation is occurring. It also may indicate whether infection, polyps, or abnormal cells are present. If a patient's Pap smear indicates abnormal cells, a cervical or endocervical biopsy may be performed to rule out or diagnose cervical cancer. Procedure 39-3, at the end of this chapter, explains how to assist with a cervical biopsy.

To assist with these biopsies, you must have knowledge of the female anatomy, the order of the procedure, and the instruments used. You also will need to instruct patients about having an escort, appropriate clothing, and any special dietary restrictions. A careful medical history must be obtained to screen for problems like possible allergic reactions. The day before the biopsy, you might call the patient to confirm the appointment and address any concerns. A biopsy is considered minor surgery and consequently requires observance of standard precautions and sterile technique. Depending on the extent and site of the biopsy, the patient may receive sedation or local anesthesia. During the procedure, you may be responsible for clipping excess material from sutures (stitches) and any other special assistance the licensed practitioner requests. You must place the biopsy specimen in a sterile, solution-filled container provided by the laboratory. You also may assist with or perform the cleaning and bandaging of the site after the procedure. Because of the nature of the procedure, emotional support should be provided as needed during any biopsy.

Colposcopy Colposcopy is the exam of the vagina and cervix with an instrument called a colposcope. See Figure 39-5. The licensed practitioner first cleanses the cervix with saline solution. She then cleanses the cervix with acetic acid, which makes abnormal tissue appear white. The licensed practitioner inserts the colposcope into the vagina and uses the attached magnifying lens to identify abnormal cells, such as cancerous or precancerous cells. The abnormal cells may not be cancerous but may be caused by infection or medication.

This procedure is often performed prior to a biopsy or LEEP procedure after results of a Pap smear show the

FIGURE 39-5 A colposcope is used to examine the vagina and cervix for abnormal cells.

presence of abnormal cells. LEEP procedures are described later in this chapter.

Dilation and Curettage (D&C) A D&C consists of widening the opening of the cervix (dilation) and scraping the uterine lining (curettage). Reasons for the D&C procedure include assessing the size and shape of the uterus, removing polyps and fibroids from the endometrium, obtaining endometrial specimens for biopsy, performing an abortion, and completing an incomplete miscarriage. Other diagnoses for which a D&C may be performed include abnormal uterine bleeding, abnormal menstrual bleeding, **postcoital** bleeding, spotting between periods, postmenopausal bleeding, and an imbedded intrauterine device (IUD).

The procedure is usually performed in a hospital or outpatient surgical facility. You must inform the patient that she will need to have someone take her to and from the facility and that she will have anesthesia before the licensed practitioner performs a routine pelvic exam. For the D&C procedure, the licensed practitioner swabs the vagina with an antiseptic and inserts a speculum. After dilating the cervix, the licensed practitioner uses a curette to remove a portion of the endometrium to assess the texture. Both cervical and endometrial tissue may be sent to a laboratory for examination. Exploration of the uterine cavity and removal of any abnormal growths complete the procedure. Instruct the patient not to have intercourse, take tub baths, or use tampons for 1 week after the procedure. She should also avoid strenuous activity.

Stereotactic Core Biopsy/Fine-Needle Aspiration

In a fine-needle aspiration, the licensed practitioner uses a fine needle to remove by vacuum a sample of tissue from a cyst, lump, or tumor of the breast. The term *stereotactic* means that the licensed practitioner finds the target to aspirate using three-dimensional coordinates from a radiographic mammogram, computed tomography, or MRI. This procedure may be used instead of mammography to diagnose breast

disorders in pregnant patients, thus avoiding the use of radiation. Patients with fibrocystic breast disease (involving multiple cystic lumps within the breast tissue) may have needle aspiration of a cyst followed by replacement of the cystic fluid with a steroid to prevent recurrence.

Hysterectomy A hysterectomy is the surgical removal of the uterus. If surgery includes removal of one or both fallopian tubes, it is called a hysterosalpingectomy. Surgical removal of the uterus, the fallopian tubes, and the ovaries is called a hysterosalpingo-oophorectomy. A hysterectomy or a related surgery may be performed for the following reasons: cervical or endometrial cancer; severe endometriosis; unusual bleeding; a leiomyoma, or fibroid; defects of pelvic supports; pregnancy-related problems; and pelvic adhesions or other causes of uterine pain not controllable by other methods.

Inform the patient that an abdominal hysterectomy is major surgery that requires hospitalization. It also requires preadmission urine and blood tests, cleansing enemas, and shaving of the pelvic area. Normal activities, including sexual intercourse, can usually be resumed within a few weeks. Premenopausal women who have hysterectomies or hysterosalpingectomies may begin menopause sooner than they otherwise would have. Premenopausal women who have hysterosalpingo-oophorectomies will experience menopause immediately after the surgery.

Laparoscopy A laparoscope is a long, tubular instrument. It contains fiber-optic threads that illuminate the organs and a lens that resembles a small telescope. A licensed practitioner can use the laparoscope to view the internal female organs. Laparoscopy is used to help determine the cause of **infertility** (the inability to conceive), to obtain tissue samples, to remove abnormal growths, and to surgically sterilize a patient. It is also used in the treatment of ectopic pregnancies, endometriosis, and laparoscopy-assisted hysterectomy.

During laparoscopy the patient is anesthetized and the laparoscope tube is inserted through a small incision in or around the navel. Carbon dioxide or another gas is pumped into the abdomen to spread the organs apart, making them easier to see. The patient's body is then tilted with her head lower than her hips to allow the intestines to move away from the lower abdomen. This positioning permits a clearer view of the ovaries, uterus, and fallopian tubes.

Loop Electrosurgical Excision Procedure (LEEP)

A **loop electrosurgical excision procedure (LEEP)** is when a thin wire loop electrode attached to the speculum is inserted in the vagina and used to cut away abnormal cervical tissue that was discovered during a Pap smear. The tissue is then sent to a lab for further testing. This procedure may last about 20 to 30 minutes and may be done as part of a colposcopy. A small amount of smoke may be seen during this procedure.

Cryosurgery Cryosurgery is using extremely cold temperatures to freeze and destroy abnormal tissues such as venereal warts, to treat precancerous tumors, and to control bleeding. The procedure is done through the vagina using a vaginal

EDUCATING THE PATIENT

Testicular Self-Exam

Although testicular cancer is rare, it is currently the most common cancer in American males between the ages of 15 and 34. The American Cancer Society recommends that all men perform a monthly testicular self-exam from age 15 on to increase the chances of early detection. Although testicular cancer is one of the most curable cancers, early detection is vital to its treatment.

A TSE should be performed in the following manner after a warm shower or bath, when scrotal skin is relaxed. A medical assistant may be responsible for coaching the patient through the steps of this technique.

1. The man first observes the testes for changes in appearance, such as swelling. He then manually examines each testicle, gently rolling it between the fingers and thumbs of both hands to feel for hard lumps (see Figure 39-6).
2. After examining each testicle, the man should locate the area of the epididymis and spermatic cord and know these are normal structures. This area can be felt as a cord-like structure originating at the top back of each testicle.

FIGURE 39-6 Males from age 15 on should perform a monthly testicular self-exam.

speculum and a probe. Compressed gases flow through the probe, making it as low as -50°C . The extreme cold freezes and kills the tissues. A second treatment might be done after 3 minutes. Patients may experience slight cramping during the procedure. After the procedure, sexual intercourse and douching are avoided for up to two weeks, and discharge may be seen.

▶ Assisting in Urology

LO 39.4

The urologist focuses on the male and female urinary systems as well as the male reproductive system. Urologists perform surgical procedures such as hernia repairs and vasectomies. In a urologist's office, you would assist with general exams; collect and process urine, blood, and other specimens; obtain cultures; and participate in patient education about conditions and about presurgical and postsurgical care. So you need to understand the urinary system and the diseases and disorders you are likely to encounter.

You must be thorough when you take a patient's history for a urologist. Much information about urinary problems is obtained by questioning the patient about changes in frequency or urgency of urination, difficulty or pain with urination (dysuria), and incontinence. The physical exam usually includes palpation of the kidneys and bladder and visual inspection of the external genitalia. Women are usually examined in the lithotomy position. Men are typically seated when the exam begins. During the examination of the male reproductive system, the urologist inspects and palpates the patient's penis and scrotum. The genitalia are usually examined with the patient standing and the chest and abdomen

draped. The physician usually examines the inguinal region for a hernia and, in men over 40, checks the prostate gland. This gland is examined by digital insertion into the rectum. The physician instructs the patient as needed in performing a regular testicular self-exam (TSE). This instruction, discussed in the *Educating the Patient* feature Testicular Self-Exam, may also be your responsibility.

▶ Urologic Diagnostic Tests and Procedures

LO 39.5

Urologists sometimes use imaging techniques such as CT scans and MRIs. Pyelography is an X-ray of the kidney area with an iodine-based contrast agent. It is used to diagnose renal (kidney-related) disorders. Urologists also use several other diagnostic techniques.

Urine and Blood Tests

Urinalysis (analysis of the urine) is the most commonly ordered test in a urology practice. Urine can be tested for the presence of bacteria, blood, and other substances. Blood testing is also done for a variety of reasons, including monitoring for dysfunctions of the prostate gland and for certain sexually transmitted infections (STIs). For example, a PSA (prostate-specific antigen) blood test is done to screen for prostate cancer.

Semen Analysis and Smears

Semen samples may be obtained to determine fertility. This test is done if a couple finds themselves unable to conceive

or if the patient has had a vasectomy. A **vasectomy** is surgical sterilization by cutting the vas deferens. This is the tube that allows semen to pass outside the body. The patient usually collects these samples at home, but you may be required to provide the patient with a container, written instructions, and laboratory paperwork. Smears are used in diagnosing infections.

Cystometry

Cystometry is used to measure urinary bladder capacity and pressure. A catheter is passed through the urethra into the bladder. Then the physician fills the bladder with carbon dioxide gas. The test results are examined to diagnose bladder function disorders.

Cystoscopy

In cystoscopy, the physician examines the walls of the bladder and urethra by visualization and inspection. A viewing

instrument called a cystoscope is used for this procedure. The cystoscope is inserted into the bladder through the urethra.

Testicular Biopsy

Testicular biopsy, an invasive procedure, involves obtaining a tissue sample of a mass for laboratory examination. The patient will need your emotional support because he will most likely be very anxious about the nature of the lump.

► Diseases and Disorders of the Reproductive and Urinary Systems

LO 39.6

Many of the diseases and disorders encountered in OB/GYN and urology practices have been mentioned in the context of the procedures in this chapter. Tables 39-4 and 39-5 outline common obstetric, gynecologic, and urologic diseases and disorders.

TABLE 39-4 Common Obstetric and Gynecologic Diseases and Disorders

Condition	Description	Treatment
Cancer	Common occurrence in cervix, endometrium (uterus), and ovaries; cells divide uncontrollably, eventually forming a tumor or other growth of abnormal tissue; most often seen in women between the ages of 50 and 60; symptoms differ for each type of cancer	Surgery (hysterectomy), radiation, chemotherapy, hormones; for ovarian cancer, surgical removal of all reproductive organs, affected lymph nodes, appendix, and some muscle tissue, followed by chemotherapy (to extend survival time)
Ectopic pregnancy	Fertilized egg unable to move out of fallopian tube into uterus for implantation; patient experiences pain within a few weeks of conception; can be fatal	Surgery to remove the embryo from the fallopian tube before the tube ruptures
Endometriosis	Endometrial tissue present outside uterus, usually in pelvic area; not life-threatening but may cause sterility; symptoms include abnormal menstruation and pain (sometimes severe) in lower abdominal area and back	Hormone therapy, hysterectomy for severe cases, endometrial ablation (1-day surgery, alternative to hysterectomy), leuprolide acetate injection
Fibrocystic breast disease	Benign, fluid-filled cysts or nodules in breast; sometimes confused with malignant growths in breast until complete diagnostic tests are performed; symptoms include pain and tenderness	Depending on severity, vitamin E supplements, hormones, compresses, analgesics, aspiration, biopsy, restricted caffeine intake
Fibroids, or leiomyomas	Common, benign, smooth tumors of muscle cells (not fibrous tissue) grouped in uterus; symptoms include excessive menstruation and bloating; diagnosis by bimanual examination and ultrasound	Surgery for severe cases
Menstrual disturbances	May be (1) amenorrhea (absence of menstruation), (2) dysmenorrhea (painful menstruation), (3) menorrhagia (excessive amount of menstrual flow or prolonged period of menstruation), or (4) metrorrhagia (bleeding between menstrual periods)	Treatment according to symptoms; analgesics; possibly D&C or cryosurgery; for severe cases, hysterectomy
Ovarian cysts	Sacs of fluid or semisolid material, usually benign and without symptoms; occur anytime between puberty and menopause; extensive ovarian cysts may cause pelvic discomfort, lower back pain, and abnormal bleeding	Analgesics and bed rest if severe pain; hormone therapy; surgery is usually reserved for cysts that rupture or are large enough to put pressure on surrounding organs
Pelvic inflammatory disease (PID)	Acute, chronic infection of reproductive tract; causes include untreated STIs, such as gonorrhea and chlamydia, and organisms such as staphylococci and streptococci; symptoms include vaginal discharge, fever, and general discomfort	Antibiotics

(Continued)

TABLE 39-4 Common Obstetric and Gynecologic Diseases and Disorders

Condition	Description	Treatment
Pelvic support problems (uterine prolapse, rectocele, cystocele)	Abnormal weakening of vaginal tissue, unusual increase in abdominal pressure, congenital weakening (weakness since birth); symptoms include urine leakage, pelvic heaviness (“bottom falling out”), pain or discomfort in pelvic area, pulling or aching feeling in lower back, abdomen, or groin	Kegel or perineal exercises to strengthen muscles, insertion of pessary (device to hold pelvic organs in place), surgery to repair muscles, physical therapy
Polyps	Red, soft, and fragile growths, with slender stem attachment, sometimes found on mucous membranes of cervix or endometrium; may cause pain	Depending on size and shape, may be removed in office or hospital
Premenstrual dysphoric disorder (PMDD)	A severe form of premenstrual syndrome that affects 5% of women; symptoms have a very disrupting effect on the patient’s life; screening tests and physician evaluation are necessary for diagnosis	Medications, including antidepressants, anti-anxiety drugs, analgesics, hormones, and diuretics; exercise, relaxation, diet modification, vitamins, minerals, and herbal preparations are also useful
Premenstrual syndrome (PMS)	Symptoms include swelling, bloating, weight gain, breast tenderness, headaches, and mood shifts 1 week to 10 days before menstruation	Vitamins, diuretics, hormones, oral contraceptives, tranquilizers, other medications; stress-reduction methods as needed; restricted intake of dietary sodium, alcohol, and caffeine
Sexual function disorders	Interruption or lack of sexual response cycle (excitement, plateau, orgasm, and resolution); unhealthy view of one’s feelings about oneself as a woman and feelings toward sex; sometimes caused by painful intercourse, abusive partner, unrealistic demands on oneself, or menopause	Counseling (for both woman and partner) to teach relaxation, effective communication, and identification of cycle stages and natural responses
Vaginitis	Inflammation of vagina caused by bacteria, viruses, yeasts, or chemicals in sprays, douches, or tampons; symptoms include itching, redness, pain, swelling	Treatment prescribed according to cause; avoiding douches, tampons, tight pants, wiping from back to front, sometimes avoiding sex during treatment

TABLE 39-5 Common Urologic Diseases and Disorders

Condition	Description	Treatment
Epididymitis	Bacterial infection of the epididymis; causes pain, swelling, and sometimes fever	Rest and antibiotic medications
Hydrocele	Excess fluid in the scrotum; usually caused by infection of the epididymis or testes; can also result from a congenital defect or after injury	Aspiration of fluid to relieve discomfort
Impotence	Inability either to achieve or to maintain an erection; the cause may be physical, as when it results from cardiovascular or endocrine disease, or it may be a side effect of a medication such as certain diuretics and chemotherapy agents; the cause may also be psychological or emotional	Depends on the cause or causes and may include medication, counseling, or surgical procedures
Incontinence	Loss of bladder control, which results in anything from mild urine leaking to uncontrollable wetting; most bladder-control problems happen when muscles are too weak or too active; stress incontinence occurs when the muscles that keep the bladder closed are too weak and urine leaks during a sneeze, when laughing, or when lifting a heavy object	Depends on the cause and severity of the problem; may include simple exercises, medicines, special devices or procedures prescribed by a licensed practitioner, or surgery
Kidney stones	Chemical substances in the urine form crystals in the kidney, ureter, or bladder; if kidney stones cannot pass through the ureter, they can cause excruciating pain	Some stones pass; however, large stones often must be removed surgically or broken up by means of sound waves (lithotripsy) or laser techniques
Prostate cancer	The most common type of cancer among men; often no symptoms are evident, but sometimes a nodule may be felt on palpation of the prostate; if the growth is large enough, problems with urination may occur; a blood test known as a prostate-specific antigen (PSA) is used for screening in men over 50 years of age; an abnormal elevation of the PSA could indicate prostate cancer	Radiation therapy, removal of the prostate, hormone therapy, chemotherapy, biologic therapy
Prostatic hypertrophy (hyperplasia)	Enlargement of the prostate gland; occurs most commonly in men over 50; may constrict the urethra, causing difficulty in urinating and repeated urinary infections	Medications to reduce the enlarged prostate, surgery

(Continued)

TABLE 39-5 Common Urologic Diseases and Disorders

Condition	Description	Treatment
Prostatitis	Inflammation of the prostate, usually bacterial; symptoms are pain on urination and, often, fever; patients are instructed to avoid sitting for long periods	Antibiotic medications and sitz baths
Sexually transmitted infections (STIs)	Numerous diseases acquired through sexual contact; affect both reproductive and urinary systems	Prevention through education, specific treatments depending on the disease
Urethritis	Inflammation of the urethra; like cystitis, usually caused by bacterial infection	Antibiotics

Sexually Transmitted Infections (Diseases)

Sexually transmitted diseases (STDs)—diseases acquired through sexual contact with an infected person—are now frequently called sexually transmitted infections. You may have asked yourself why the term *sexually transmitted infection* is preferred instead of the term *sexually transmitted disease*. The term *infection* more accurately describes conditions in which sexual partners may not have symptoms and may not be aware that they have an infection. Many of these infections are actually curable. Also, the term *infection* carries less of a social stigma than the term *disease*. STI is now used by many

leading sexual health organizations. Urologists and gynecologists are both involved in the diagnosis and treatment of STIs.

Your role as an educator is vital in dealing with patients who have STIs. Some patients may be hesitant to ask for information. Providing educational materials in the exam room will help answer their questions and put them at ease. These materials deal with sensitive or embarrassing topics, and the patient's privacy must be maintained. Patient education about prevention and treatment of STIs is needed. See the *Educating the Patient* feature Teaching Patients About Sexually Transmitted Infections for more information on this topic.

EDUCATING THE PATIENT

Teaching Patients About Sexually Transmitted Infections

You must provide complete and detailed information with a non-judgmental and supportive attitude when you teach patients about STIs. Begin with the principle that all STIs are preventable. The key to prevention is avoiding sexual activities in which blood, semen, or vaginal secretions pass from one person to another. Although there are various levels of protection in connection with STIs, the only absolute methods of “safe sex” are abstinence (no sex) and masturbation (self-stimulation). The next level is mutual monogamy, in which partners have sex only with each other. Emphasize that monogamy provides protection from STIs only if neither partner has an STI when the relationship begins. A final level of prevention applies to people who do not practice abstinence or mutual monogamy but wish to protect themselves and others from STIs. The following measures provide some protection:

- Use a latex condom and spermicide for every act of intercourse. (Use a latex condom during vaginal, oral, or anal sex.)
- Use only water-based lubricants with latex condoms. (Oil and petroleum-based lubricants can break down latex, causing the condom to tear or break.)
- Know all your sexual partners, and discuss STI prevention with them.
- Have a physician regularly screen you for STIs because many people, especially men, have no signs when they are infected.

- Consult a physician if any signs of STIs develop, such as a blister, a sore, discharge, a rash, or abdominal pain.

Encourage patients to ask questions and discuss any concerns they have. Explain the need to make follow-up appointments with a physician if appropriate. Teaching a patient who has been diagnosed with an STI how to treat or manage the disease is especially important. Make sure the patient understands all directions and the necessity for treatment. Bacterial infections such as chlamydia, gonorrhea, and syphilis can be cured with antibiotics as long as the patient takes all the medication in the prescribed manner. Viral infections such as AIDS, genital herpes, and genital warts cannot be cured, although they can be treated and managed to differing degrees.

Emphasize to patients with an STI that they should avoid all sexual contact until the infection has been treated completely. Many STIs can be spread through any type of genital contact, including vaginal intercourse, anal sex, and oral sex. Herpes can be spread through kissing if there are herpes sores in the mouth. Encourage patients to inform each person with whom they had sexual contact that they have contracted an STI. Explain that unless all sexual partners are treated successfully, the disease will pass back and forth indefinitely.

You can reinforce your education efforts by providing patients with materials on the prevention and treatment of STIs. Keep a variety of pamphlets, books, and other resources in your office to help patients cope with and manage STIs.

When assisting the licensed practitioner in treating a patient who has an STI, you will emphasize to the patient the importance of completing the course of therapy and avoiding sexual contact while the infection is still active. Sexual partners also

must be treated to avoid reinfection. Several types of STIs are fairly common. Other types are very serious. Review the chapters *The Reproductive Systems* and *Microbiology and Disease* to become familiar with these infections.

PROCEDURE 39-1 Assisting with a Gynecologic Exam

WORK // DOC

Procedure Goal: To assist the licensed practitioner and maintain the client's comfort and privacy during a gynecologic exam

OSHA Guidelines:

Materials: Patient chart/progress note, gown and drape; vaginal speculum; specimen collection equipment, including cervical brush, cervical broom, and/or scraper; cotton-tipped applicator; potassium hydroxide solution (KOH); exam gloves; tissues; laboratory requisition; water-soluble lubricant; examining table with stirrups; exam light; microscopic slide(s); thin-layer collection vial (or slides if used); tissues; spray fixative; pen; and pencil

Method:

1. Gather equipment and make sure all items are in working order.

FIGURE Procedure 39-1 Step 1 Gather the necessary equipment.

© McGraw-Hill Education

2. Identify the patient and explain the procedure. The patient should remove all clothing, including underwear, and put the gown on with the opening in the front.
3. Ask the patient to sit on the edge of the examining table with the drape until the licensed practitioner arrives.
4. When the licensed practitioner is ready, have the patient place her feet into the stirrups and move her buttocks to the edge of the table. This is the lithotomy position.

RATIONALE: Putting the patient in the lithotomy position too early can cause the patient to experience back and leg cramps.

FIGURE Procedure 39-1 Step 2 Have the patient remove all clothing and put on the gown with the opening in the front.

© McGraw-Hill Education

5. Provide the licensed practitioner with gloves and an exam lamp as she examines the genitalia by inspection and palpation. Put on gloves per standard precautions guidelines.
6. Pass the speculum to the licensed practitioner. To increase patient comfort, you may place the speculum in warm water before handing it to the licensed practitioner. Lubricant is not typically recommended prior to the Pap smear because it may interfere with the test results.

(a)

FIGURE Procedure 39-1 Step 6 Hand the speculum to the practitioner when needed.

© McGraw-Hill Education

7. For the Pap (Papanicolaou) smear, be prepared to pass a cotton-tipped applicator and cervical brush, broom, or scraper for the collection of the specimens. Have the slide or vial available for the licensed practitioner to place the specimen on the slide. Depending on

the licensed practitioner, the specimen collected, the method of collection, and the method of preparation, two or more slides or collection vials may be necessary. They may be labeled based on where the specimen was collected: endocervical (E), vaginal (V), and cervical (C).

(b)

FIGURE Procedure 39-1 Step 6 A speculum is used to view the internal structures during a gynecologic exam.

© Doc-Stock/Corbis RF

FIGURE Procedure 39-1 Step 7 Label the slide for the specimen using the office protocol.

© McGraw-Hill Education

8. Once the specimen is on the slide, a cytology fixative must be applied immediately. A spray fixative is common and should be held 6 inches from the slide and sprayed lightly with a back-and-forth motion. Allow the slide to dry completely.

RATIONALE: *The fixative holds the cells in place until a microscopic exam is performed.*

Cells collected for thin-layer preparation should be washed into the collection vial and transported to an outside lab for processing and analysis.

9. Label the slides/vials immediately after processing the specimen unless office protocol requires pre-labeling the container.

RATIONALE: *Slides or vials should be immediately and properly labeled to avoid confusing one patient's specimen with another's.*

FIGURE Procedure 39-1 Step 9 Specimens should be labeled immediately after processing.

© McGraw-Hill Education

10. After the licensed practitioner removes the speculum, a digital exam is performed to check the position of the internal organs. Provide the licensed practitioner with additional lubricant as needed.
11. Upon completion of the exam, help the patient switch from the lithotomy position to a supine or sitting position.
12. Provide tissues or moist wipes for the patient to remove the lubricant and ask the patient to get dressed. Assist as necessary or provide for privacy. Explain the procedure for communicating the laboratory results.
13. After the patient has left, don gloves and clean the exam room and equipment. Dispose of the disposable speculum, specimen collection devices, and other contaminated waste in a biohazardous waste container.
14. Store the supplies, straighten the room, and discard the used exam paper on the table.
15. Prepare the requisition slip and place the specimen and requisition slip in the proper place for transport to an outside laboratory.
16. Remove your gloves and wash your hands.
17. Document the specimen and complete the laboratory log if needed (refer to Progress Note).

PROCEDURE 39-2 Assisting During the Exam of a Pregnant Patient

Procedure Goal: To assist the licensed practitioner and meet the special needs of the pregnant woman during the general physical exam

OSHA Guidelines:

Materials: Patient education materials, examining table, exam gown, drape

Method:

Providing Patient Information

1. Identify the patient and introduce yourself.
2. Assess the patient's need for education by asking appropriate questions and having the patient describe what she already knows about the information you are providing.
3. Provide any appropriate instructions or materials.
4. Ask the patient whether she has any special concerns or questions about her pregnancy that she might want to discuss with the licensed practitioner.
5. Communicate the patient's concerns or questions to the licensed practitioner; include all pertinent background information on the patient.

RATIONALE: *Maintains your scope of practice and ensures that the patient receives correct information*

Ensuring Comfort During the Exam

6. Identify the patient and introduce yourself.
7. Wash your hands.
8. Explain the procedure to the patient.
9. Provide a gown or drape and instruct the patient in the proper way to wear it after disrobing. (Allow the patient privacy while disrobing and assist only if she requests help.)
10. Assist the patient onto the examining table. Ask the patient to step on either the stool or the pullout step of the examining table.
RATIONALE: *Pregnant women may need assistance during the later stages of pregnancy.*
11. Help the patient into the position requested by the licensed practitioner, observing the patient for any difficulties she may have in achieving the requested position.
12. Provide and adjust additional drapes as needed.
13. Minimize the time the patient must spend in uncomfortable positions by making sure that the licensed practitioner has all supplies and equipment for the exam before it begins.
14. If the patient appears to be uncomfortable during the procedure, ask whether she would like to reposition herself or take a break; assist as necessary.
15. To prevent pelvic pooling of blood and subsequent dizziness or hyperventilation, allow the patient time to adjust to sitting before standing after she has been lying on the examining table. Assist the patient off the exam table if needed.

PROCEDURE 39-3 Assisting with a Cervical Biopsy

WORK // DOC

Procedure Goal: To assist the physician in obtaining a sample of cervical tissue for analysis

OSHA Guidelines:

Materials: Patient chart/progress note, laboratory requisition form, gown and drape, tray or Mayo stand, disposable cervical biopsy kit (disposable forceps, curette, and spatula in a sterile pack), transfer forceps, vaginal speculum, biopsy specimen container, clean basin, sterile cotton balls, sterile gauze squares, sanitary napkin

Method:

1. Identify the patient and introduce yourself.
2. Look at the patient's chart and ask the patient to confirm information or explain any changes. Specific patient

information you need to ask about and note in the chart includes the following:

- Date of birth and Social Security number (verify that you have the correct chart for the correct patient)
 - Date of last menstrual period
 - Method of contraception, if any
 - Previous gynecologic surgery
 - Use of hormone replacement therapy or other steroids
3. If within your scope of practice, describe the biopsy procedure to the patient, noting that a piece of tissue will be removed to diagnose the cause of her problem. Explain that it may be painful but only for the brief moment during which tissue is taken.
 4. Give the patient a gown, if needed, and a drape. Direct her to undress from the waist down and to wrap the drape around herself. Tell her to sit at the end of the examining table.
 5. Wash your hands and put on exam gloves.

6. Using sterile method, open the sterile pack to create a sterile field on the tray or Mayo stand and arrange the instruments with transfer forceps. Add the vaginal speculum and sterile supplies to the sterile field.
RATIONALE: *The instruments and supplies must stay sterile because this is an invasive procedure.*
7. When the physician arrives in the exam room, ask the patient to lie back, place her heels in the stirrups of the table, and move her buttocks to the edge of the table.
RATIONALE: *Placing the patient in the lithotomy position too early can cause the patient's back and legs to cramp.*
8. Assist the physician by arranging the drape so that only the genitalia are exposed, and place the light so that the genitalia are illuminated.
9. Use transfer forceps to hand instruments and supplies to the physician as he requests them. You may don sterile gloves and hand the physician supplies and instruments directly.
10. When the licensed practitioner is ready to obtain the biopsy, tell the patient that it may hurt. If she seems particularly fearful, instruct her to take a deep breath and let it out slowly.
11. When the physician hands you the instrument with the tissue specimen, place the specimen in the specimen container and discard the instrument in the appropriate container.
12. Label the specimen container with the patient's name, the date and time, cervical or endocervical (as indicated by the physician), the physician's name, and your initials.
13. Place the container and the cytology laboratory requisition form in the envelope or bag provided by the laboratory.

14. When the physician has completed the procedure and removed the speculum, properly clean instruments as needed and dispose of used supplies and disposable instruments. Metal speculums, if used, should be placed in a clean basin for later sanitization, disinfection, and sterilization.
15. Remove the gloves and wash your hands.
16. Tell the patient that she may get dressed. Inform her that she may have some vaginal bleeding for a couple of days, and provide her with a sanitary napkin. Instruct her not to take tub baths or have intercourse and not to use tampons for 2 days. Encourage her to call the office if she experiences problems or has questions.
17. Document the procedure as appropriate (refer to Progress Note).

SUMMARY OF LEARNING OUTCOMES	
LEARNING OUTCOMES	KEY POINTS
39.1 Carry out the role of the medical assistant in the medical specialty of gynecology.	Medical assistants assist with gynecologic exams, provide patient teaching for OB/GYN and breast health issues, and must handle cervical and other specimens correctly.
39.2 Carry out the role of the medical assistant in the medical specialty of obstetrics.	Medical assistants assist with examinations for pregnant females, providing for their needs, and provide education for the pregnant patient and new mother.
39.3 Identify diagnostic and therapeutic procedures performed in obstetrics and gynecology.	Diagnostic and therapeutic procedures performed in OB/GYN include pregnancy tests, tests for STIs, radiologic tests such as mammograms, fetal screening, Pap smears, D&C, and fine-needle aspiration.
39.4 Relate the role of medical assisting to the medical specialty of urology.	Medical assistants assist with urologic exams and diagnostic tests. Patient education for urologic patients regarding TSE and other information is also the duty of a medical assistant working in urology.

LEARNING OUTCOMES**39.5 Identify diagnostic tests and procedures performed in urology.****39.6 Recognize diseases and disorders of the reproductive and urinary systems.****KEY POINTS**

Various urologic diagnostic tests and procedures are performed, including semen analysis, cystometry, cystoscopy, and testicular biopsy.

Diseases and disorders of the reproductive and urinary systems are listed for review in Table 39-4, Common Obstetric and Gynecologic Diseases and Disorders, and Table 39-5, Common Urologic Diseases and Disorders.

Recall Raja from the beginning of the chapter. Now that you have read the chapter, answer the following questions regarding her case.

1. How often should Raja have a pelvic exam, cervical cytology, HIV screen, and mammogram?

2. What should have been discussed with Raja before she had the mammogram?

3. How is stereotactic fine-needle biopsy performed?

E X A M P R E P A R A T I O N Q U E S T I O N S

- 1.** (LO 39.2) A pregnant patient, Molly Holiday, has started feeling the movement of her baby. What is her current stage of pregnancy?
 - a. 1st trimester
 - b. Menarche
 - c. 3rd trimester
 - d. 2nd trimester
 - e. 4th trimester
- 2.** (LO 39.4) A TSE is
 - a. Surgery that involves bypassing a blockage in the heart
 - b. An imaging procedure that uses magnets and radio waves
 - c. An examination of the testicles by the patient
 - d. Scanning of the blood flow and metabolic activity in the brain
 - e. An examination of the testicles by the physician
- 3.** (LO 39.2) A pregnant patient is monitoring her blood glucose level with a glucometer. She most likely has
 - a. Type 2 diabetes
 - b. Type 1 diabetes
 - c. Gestational diabetes
 - d. Hyperthyroidism
 - e. Diabetes mellitus
- 4.** (LO 39.1) Which of the following indicates the LMP?
 - a. The last day of the last menstrual period
 - b. The first day of the last menstrual period
 - c. A late menstrual period
 - d. A likely menopausal pregnancy
 - e. The heaviest flow day of the last menstrual period
- 5.** (LO 39.1) A speculum is used to
 - a. Evaluate for a DVT
 - b. Evaluate the LMP
 - c. Perform a basic physical exam
 - d. Perform a vaginal exam
 - e. Examine the breasts
- 6.** (LO 39.3) Which of the following patients would *most* likely have an alpha fetoprotein test?
 - a. 28-year-old male patient with urinary frequency and urgency
 - b. 36-year-old female in her 3rd trimester of pregnancy
 - c. 27-year-old female with vaginal discharge
 - d. 54-year-old female with urinary incontinence
 - e. 35-year-old female in her 2nd trimester of pregnancy

7. (LO 39.5) Which of the following diagnostic tests would *least* likely be performed on a male urologic patient?
- Colposcopy
 - Testicular biopsy
 - Semen analysis
 - Urinalysis
 - Cystoscopy
8. (LO 39.1) At what age should most women start having yearly mammograms, according to the American Cancer Society and National Cancer Institute?
- 20
 - 30
 - 40
 - 50
 - 65
9. (LO 39.6) Your 27-year-old female patient has a menstrual disturbance. Which of the following does she *least* likely have?
- Amenorrhea
 - Menorrhea
 - Dysmenorrhea
 - Metrorrhagia
 - Menorrhagia

10. (LO 39.6) Your male patient has an infection that is not an STI. Which of the following is most likely the problem?
- Hydrocele
 - Vaginitis
 - Epididymitis
 - Gonorrhea
 - Prostatic hypertrophy

SOFT SKILLS SUCCESS

A young adult female patient begins asking you questions regarding birth control choices. She states she feels uncomfortable asking her physician, Dr. Buckwalter. Can you act as an “intermediary” for her with Dr. Buckwalter? Do you have any ideas to help her regarding her fears surrounding the need for this discussion?

Go to PRACTICE MEDICAL OFFICE and complete the module Clinical - Interactions.

Assisting in Pediatrics

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Chris Matthews	11/19/20XX	NKA
PATIENT INFORMATION	Attending	MRN	Other Information
	Alexis N. Whalen, MD	324-95-786	Home-schooled; parents refused immunizations

Chris Matthews is a 7-year-old male patient whose mother states he has had diarrhea for 3 days. He kept her up all night last night going to the bathroom at least three times. He says his stomach hurts but has not vomited, although he is eating very little. While you are preparing to weigh the patient, he initially does not want to get on the scale and begins to cry.

© McGraw-Hill Education

After his mother has persuaded him to get on the scale and you have obtained all the measurements and vital signs, you check his immunization record. While doing so, you see a note on Chris's chart indicating he is home-schooled and his parents are against immunizations.

Keep Chris in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 40, you will be able to:

- 40.1** Relate growth and development to pediatric patient care.
- 40.2** Identify the role of the medical assistant during pediatric examinations.
- 40.3** Discuss pediatric immunizations and the role of the medical assistant.
- 40.4** Explain variations of pediatric screening procedures and diagnostic tests.
- 40.5** Describe common pediatric diseases and disorders and their treatment.
- 40.6** Recognize special health concerns of pediatric patients.

KEY TERMS

- | | |
|------------------|-----------------------|
| addiction | jaundice |
| bilirubin | menarche |
| contraindication | moro reflex |
| enuresis | phenylketonuria (PKU) |
| fontanel | puberty |
| growth chart | substance abuse |
| immunizations | |

- I.C.6** Compare structure and function of the human body across the life span
- I.C.8** Identify common pathology related to each body system including
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- I.P.1** Measure and record:
 - (a) blood pressure
 - (b) temperature
 - (f) weight
 - (g) length (infant)
 - (h) head circumference (infant)
- I.P.3** Perform patient screening using established protocols
- I.P.7** Administer parenteral (excluding IV) medications
- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.9** Assist provider with a patient exam
- I.A.1** Incorporate critical thinking skills when performing patient assessment
- I.A.2** Incorporate critical thinking skills when performing patient care
- I.A.3** Show awareness of a patient's concerns related to the procedure being performed
- II.C.6** Analyze healthcare results as reported in:
 - (a) graphs
- II.P.4** Document on a growth chart
- X.C.12** Describe compliance with public health statutes
 - (b) abuse, neglect, and exploitation
 - (c) wounds of violence
- X.P.3** Document patient care accurately in the medical record

2. Anatomy and Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- c. Apply various medical terms for each specialty

4. Medical Law and Ethics

- a. Follow documentation guidelines

5. Psychology of Human Relations

- a. Respond appropriately to patients with abnormal behavior patterns
- c. Intervene on behalf of the patient regarding issues/concerns that may arise, i.e. insurance policy information, medical bills, physician/provider orders, etc.
- d. Discuss developmental stages of life
- e. Analyze the effect of hereditary, cultural, and environmental influences on behavior

9. Clinical Procedures

- b. Obtain vital signs, obtain patient history, and formulate chief complaint
- c. Assist provider with general/physical examination
- d. Assist provider with specialty examination including cardiac, respiratory, OB-GYN, neurological, gastroenterology procedures
- e. Perform specialty procedures including but not limited to minor surgery, cardiac, respiratory, OB-GYN, neurological, gastroenterology
- f. Prepare and administer oral and parenteral medications and monitor intravenous (IV) infusions
- j. Make adaptations with patients with special needs

► Introduction

Pediatrics is a specialty area of medicine that involves the care of children up to the age of 18, and in some cases 21. To be a good pediatric medical assistant, you must first like children of all ages. If you do, you will be better able to relate to them and to communicate with them effectively. The pediatrician specializes in the healthcare of children, monitoring their development and diagnosing and treating their illnesses. Just as with other specialty fields, there are subspecialties of pediatrics, such as surgery and oncology.

As a medical assistant working in pediatrics, your primary areas of responsibility include parent or caregiver education,

adherence to immunization schedules, and recognition of special health concerns. You also will assist with the pediatric patient's physical exam and treatment. Relating to the child, as well as being a liaison between the parent or caregiver and the physician, is essential to your job.

► Developmental Stages and Care LO 40.1

Different periods of childhood present different changes and challenges. As discussed in the *Interpersonal Communication* chapter, understanding lifespan development will, among other things, enhance your communication skills. This chapter focuses on the life stages from birth through the teenage years.

Understanding the child's stages of growth and development will improve your skills as a medical assistant. During each stage of growth, the following developmental milestones occur:

- Physical development is the actual bodily changes that occur.
- *Intellectual-cognitive development* refers to the thinking skills the child is developing.
- *Psycho-emotional development* refers to the changes in feelings experienced during a particular period.
- Social development is the way a person relates to others.

The stages of growth and development for pediatric patients include neonate, infant, toddler, preschooler, elementary school child, middle school child, and adolescent. As you explore each stage, you will also review the related aspects of care to help you provide the necessary care and patient education.

Neonate

An infant is called a *neonate* from birth to 1 month of age. Many changes take place in this short time.

Physical Development The full-term infant usually weighs between 7 and 9 pounds and is 18 to 22 inches in length. The newborn infant's head seems large in comparison to the rest of her body. No wonder—the head is usually one-fourth of the infant's entire length! An adult head is usually only about one-ninth of the body length. An infant's head has two soft spots, or **fontanel**s, which are tough, fibrous cartilage (Figure 40-1). The anterior, or front, fontanel is diamond-shaped. The baby's pulse can sometimes be seen here. The infant can move her head from side to side. However, because

FIGURE 40-1 Be aware of the newborn's fontanel, or "soft spots." These areas are open at birth so that the brain can grow. They close as the infant ages.

the neck muscles are not strong enough to hold the head up, the person holding the infant must provide support.

The newborn baby's skin is usually loose, wrinkled, and somewhat red in appearance. During the first week of life, this skin may start to peel. This is not harmful, and nothing needs to be done about it. The part of the umbilical cord still attached to the baby's body is a "stump" about 1 to 1½ inches in length. At birth it has a white, waxy appearance, then turns darker and usually falls off around the tenth day of life (Figure 40-2).

Sometimes infants develop neonatal **jaundice**—a yellowish color of the skin—in the first few days of life. This is caused by an accumulation of **bilirubin**, the waste product from the normal breakdown of the red blood cells. Babies have large numbers of red blood cells at birth. Their immature liver is unable to handle the breakdown of these cells. The waste product accumulates, giving the skin a yellowish tint. The whites of the eyes also may appear yellow, and the urine and feces may have a dark yellow color.

Certain reflexes can be observed in the newborn. Some are protective. For example, blinking is a reflex that protects the eyes. Everyone, including newborns, has this reflex. Other reflexes are due to the infant's immature nervous system. For example, the **moro reflex** is one in which the infant feels as if she is falling. The arms spread out and then back in and crying often occurs. The physician will check reflexes as part of an examination.

Infants can see objects within 8 inches of their eyes. They probably detect brightness rather than color. Their eyes tend to turn outward or may even cross. Infants seem to prefer high-pitched tones.

Intellectual-Cognitive Development Newborns will become calm when picked up and held firmly. They tune out disturbing stimulation by sleeping.

Social Development Early on, infants respond to stimulation and establish an individual activity pattern. Generally, an infant responds to a soft, gentle voice and tries to focus

FIGURE 40-2 The umbilical cord usually falls off when the baby is about 10 days old.

© Ian Boddy/Science Source

on the voice and face. Newborns can show excitement and distress.

Aspects of Care: Neonate Consider the following when caring for neonates or providing parent or caregiver education.

- Sponge baths with tepid water and limited amounts of mild infant cleansing soap are given until the cord has fallen off. The infant's face should be washed with tepid water. No oil should be rubbed on the baby. Lotions and powders also should be avoided.
- If an infant is to be breast-fed, parents are given instruction about frequency of feedings, duration of feedings, and care of the mother and her breasts while breast-feeding. If an infant is to be bottle-fed, parents must be given instruction about the type of formula and how to prepare it correctly. Parents also should be taught about bowel movements and spitting up.
- The treatment for jaundice in the newborn is keeping the infant well hydrated with breast milk or formula. If necessary, the infant is placed under ultraviolet light. These bright lights can damage the infant's eyes, so eye protection is necessary during this treatment. Some neonates may need to use a bili-blanket, which is a type of phototherapy device that helps the infant eliminate the bilirubin, thus improving the jaundice (Figure 40-3). Blood tests will be performed fairly often to ensure that the bilirubin level does not become dangerously high. Other newborn blood tests are performed, including a screening test for phenylketonuria (PKU). See the *Points on Practice* box Testing for Phenylketonuria (PKU) for more information about this important test.

The Infant: 1 Month to 1 Year

Many changes occur in an infant during the first year. Parents cherish the wonder of their growing, developing child during this period.

FIGURE 40-3 A newborn with excessive bilirubin may be sent home with an ultraviolet light bili-blanket to help reduce the jaundice.

© Aaron Haupt / Science Source

Physical Development Growth is rapid during the first year of life. Infants triple their birth weight by their first birthday. They develop in a cephalocaudal fashion, with the earliest development starting at the head and moving down. Infants first gain control of the head, neck, and shoulders, and then the arms, torso, and legs. This is why an infant finds and uses his hands before he finds and uses his feet. Larger groups of muscles develop before the smaller groups of muscles develop. The nervous system develops rapidly. Changes are seen in reflexes and in the development of coordinated movement and eye-hand coordination. The following is a brief look at some specific types of physical development in infants.

- By about 3 weeks of age, infants can focus on objects.
- By about 4 weeks, infants can follow an object with their eyes and make eye-to-eye contact. The infant can lift his head when lying on his abdomen.
- At 2 months, infants can follow objects with their eyes from one side to the other, listen to sounds, bat at objects, and respond to sounds. At this age, the infant may string together vowel sounds.

POINTS ON PRACTICE

Testing for Phenylketonuria (PKU)

Phenylketonuria (PKU) is a rare metabolic disorder. It is caused by a mutation in a gene that is responsible for creating an enzyme that breaks down phenylalanine, an amino acid found in protein-rich foods. If this amino acid is not broken down, it accumulates in the body and causes brain damage. Screening newborns for PKU is required in all states.

The screening test is a qualitative test for the presence of phenylalanine and related substances and is usually done 24–48 hours after birth. The newborn must ingest proteins prior to the test to ensure accuracy. Though this test is usually done in the hospital prior to discharge, there may be occasions when it is done in the physician's office.

To perform the test, a capillary puncture is done on the infant's heel. Three or four drops of blood are collected on a card or paper. Before the test is performed, the card must be filled out completely, including the following information:

- Mother's name and address
- Ordering physician's name and contact information
- Baby's name, date of birth, and weight
- Gestational age
- Date and time of the collection

- By 3 months, an infant may raise the head and shoulders while on the abdomen and may hold up the head (Figure 40-4). When the infant is pulled to a sitting position, the head remains in line with the backbone.
- By 4 months, the infant may roll from stomach to back and may begin to play with a rattle placed in the hand. Teething may begin at this time.
- By 5 months, the infant may transfer a rattle from one hand to the other.
- At 6 months, the infant rolls from back to stomach, may be able to sit up briefly, and can reach to retrieve a dropped object. The two bottom front teeth have probably erupted, or emerged, from the gums.
- At 9 months, the infant is able to sit and to creep on hands and knees. The infant is beginning to use the pincer grasp. The infant can put consonants with vowels and make repetitive sounds such as “mama” and “dada.”
- At 12 months, the child can hold on to a piece of furniture and move around it, perhaps taking a step or two. With tooth development and the pincer grasp, the infant can pick up and eat small pieces of food.

Intellectual-Cognitive Development At 1 month of age, an infant can make contact. This progresses to recognition of familiar faces and then to “making faces” at 4 to 5 months. At around 6 months of age, the child is making babbling sounds and by 9 months is able to play games like peek-a-boo. The infant begins to understand cause and effect. If the infant drops a toy and someone retrieves it, the infant will drop it again. This becomes a game. At 12 months, an infant can follow simple directions.

Psycho-Emotional Development By the time a child is 1 month old, he or she can smile at another smiling face. By 3 months, the infant smiles spontaneously and displays pleasure in making sounds. At 4 months, the infant can vocalize a mood. At 6 months, there may be abrupt mood changes. At 9 months, the infant displays pleasure in playing simple

FIGURE 40-4 A 3-month-old infant should be able to hold up her head when lying on her stomach.

© Total Care Programming, Inc.

games and by 1 year has learned to express many emotions. For infants to develop physically and emotionally, it is important that their physical needs be addressed quickly and calmly.

Social Development Infants become social beings very quickly. By 1 month of age, infants are able to smile. At 3 months, the infant responds to voices. This can be seen when the infant pays attention and coos along with a person speaking in a quiet and gentle manner. At 6 months, the baby “babbling” and is interested in his or her own voice. Imitative play becomes an important part of the infant’s interaction with others. At 9 months, the first development of words can be observed. This leads to increased interaction with family and others.

Aspects of Care: 1 Month to 1 Year Consider the following when caring for infants or providing parent or caregiver education.

- Regular health checkups and immunizations should be followed. Immunizations will be discussed later in this chapter.
- Infants need tactile stimulation for growth and development. Physical contact and cuddling, as well as prompt attention to their needs, help infants develop a sense of security and trust, which is necessary for them to thrive.
- In the first 4 to 6 months, the mother’s breast milk or infant formula meets the growing infant’s needs. The physician will provide guidance about the introduction of solid foods to the diet. You may be asked to assist the physician in guiding the parent or caregiver regarding the diet of a pediatric patient. Table 40-1 provides basic pediatric guidelines; however, always follow the policy of the facility where you are employed. In addition, be aware that dietary guidelines change with research.
- Ensure infant safety. See the *Educating the Patient* feature Keeping Infants and Toddlers Safe.

The Toddler: 1 to 3 Years

Children from the age of 1 to 3 years need constant attention from parents and others. Although they grow less rapidly during this period, their growth is still fast, and their communication skills begin to take shape in their use of language.

Physical Development Weight gain slows between 1 and 2 years. The arms and legs grow more than the trunk and head, and now seem to be in proportion to the child’s overall size. Girls usually reach half of their adult height between 1½ and 2 years of age; boys reach half of their expected adult height between 2 and 2½ years.

Growth charts, as shown in Figure 40-5, are used to determine a child’s growth in relation to average rates. The growth charts consist of percentile curves. Percentiles rank the position of an individual by indicating what percentage of the referenced population the individual would equal or exceed. For example, on the weight-for-age growth charts, an 18-month boy whose weight is at the 90th percentile weighs the same or more than 90 percent of the reference population

TABLE 40-1 Pediatric Dietary Guidelines*

AGE GROUP	RECOMMENDATIONS	SPECIFIC CONCERNS
Birth to 4 months	Breast milk every 2 to 4 hours or formula six to eight times a day with 2 to 3 ounces per feeding.	- Never give infants honey; it may contain botulism spores. - Infants may need to be woken up at night if they are not eating enough during the day.
4 to 6 months	Introduce 1 to 2 tablespoons of cereal mixed with formula or breast milk two times a day. Gradually increase to 3 to 4 tablespoons.	- Do not give cereal in a bottle unless directed by the physician. - Never put the infant to bed with a bottle in the mouth. This promotes tooth decay.
6 to 8 months	- Introduce strained vegetables and fruits. Give 2 to 3 tablespoons and offer about four servings per day. - Teething foods such as toast strips, unsalted crackers, and teething biscuits may also be introduced.	Introduce finger foods if recommended by the physician, but avoid things such as apple chunks or slices, grapes, hot dogs, sausages, peanut butter, popcorn, nuts, seeds, round candies, and hard chunks of uncooked vegetables.
8 to 12 months	- Introduce strained or finely chopped meats. - Increase vegetables and fruits to 3 to 4 tablespoons, four times a day. - Include egg yolks 3 to 4 times per week.	- Start breast-fed babies on meat at 8 months to improve iron intake. - Start weaning off the bottle. - Do not give whole milk to infants under the age of 1.
1 to 2 years	- Whole milk can replace breast milk or formula. - Include fruits, vegetables, meats, breads, and grains.	- If a child does not like a food on the first attempt, try again later. - Offer one new food at a time.
2 years and older	- Balance dietary calories with physical activity to maintain normal growth. - Eat vegetables and fruits daily; limit juice intake. - Use vegetable oils and soft margarines low in saturated fat and trans fatty acids instead of butter or most other animal fats in the diet. - Eat whole-grain breads and cereals rather than refined-grain products. - Reduce the intake of sugar-sweetened beverages and foods. - Use nonfat (skim) or low-fat milk and dairy products daily. - Eat more fish, especially oily fish, broiled or baked. - Reduce salt intake, including salt from processed foods.	- Control when food is available and when it can be eaten. Regular meals and healthy snacks should be provided. - Have regular family meals that include social interaction with the family. - Teach about food and nutrition at the grocery store and when cooking meals. - Counteract inaccurate information from the media and other influences. - Teach other care providers (such as day care, babysitters) about what you want your children to eat. - Serve as role models and lead by example; “do as I do” rather than “do as I say.” - Promote and participate in regular daily physical activity.

*Infants and children vary in growth and development; information intended as guidelines only. Adapted from Medline Plus <http://www.nlm.nih.gov/medlineplus> and American Academy of Pediatrics <http://pediatrics.aappublications.org/>.

of 18-month boys and weighs less than 10 percent of the 18-month boys in the reference population. Pediatric growth charts are used as a clinical tool for health professionals to determine if a child's growth is adequate. Procedure 40-2, at the end of this chapter, provides more information about how to record height, weight, and head circumference on a growth chart.

Most toddlers will walk independently by 15 months of age. At 18 months, a toddler can squat to reach for a toy, kneel and remain upright, and precisely perform the pincer grasp. The toddler may use a spoon for self-feeding. By 2 years of age, the child can run, throw a ball, and scribble with a pencil. The child may want to feed herself. At 3 years, the child is very active. Children of this age can dress themselves, ride a tricycle, draw simple shapes, and use a pair of child's scissors. Many children are toilet-trained between 2 and 3 years of age.

Intellectual-Cognitive Development During the toddler years, the child begins to learn about the world through play. Children enjoy imitating sweeping, raking, and making things they have seen adults make. A major task for the toddler is to develop independence. Toddlers are curious about their world, and their play may involve experimenting.

The toddler progresses with speech in the following ways:

- Speaks a few single words at 12 to 15 months
- Makes sentences containing 6 to 20 words at 2 years
- Repeats nursery rhymes at 3 years

At 15 months, the child enjoys looking at books. Between 2 and 3 years of age, the toddler seems to be constantly asking “Why?” By 3 years of age, the child may participate in the retelling of familiar stories and can draw and recognize simple shapes. During the toddler years, the child also enjoys playing with blocks.

Birth to 36 months: Boys Length-for-age and Weight-for-age percentiles

FIGURE 40-5 The curved lines on these growth charts are used to chart the growth for boys from birth to age 36 months. The child's length, height, and head circumference are measured and recorded, then plotted on this graph to show progress.

Psycho-Emotional Development At 1 year of age, children are able to express many emotions. As children move from 1 year to 3 years, they gain some control over ways of expressing their feelings. Temper tantrums may become a problem between 18 months and 2 to 2½ years of age. A child of 15 months may respond to “No,” but by the time the toddler approaches 18 to 21 months, he or she is resisting authority and is the one who is saying “No!” Children of this age need consistent limits. If the child learns that a certain behavior will gain nothing, the behavior will stop fairly soon. As toddlers approach 3 years of age, they become sensitive to the feelings of others and may be characterized as affectionate.

Social Development Between 1 and 2 years, the toddler is unlikely to be able to truly play with another child. Play may involve taking toys from another child rather than sharing. Between 2 and 3 years, children become able to share and play with others. Adult guidance is necessary for the toddler to develop an awareness of what is appropriate when playing with other children. See the *Educating the Patient* feature Keeping Infants and Toddlers Safe.

Aspects of Care: 1 to 3 Years Consider the following when caring for toddlers or providing parent or caregiver education. Safety is of utmost importance. See the *Educating the Patient* feature Keeping Infants and Toddlers Safe. During the toddler years, it is also very important to allow a child to increase independence in a safe environment.

- Toddlers need opportunities to work on their fine-motor skills, such as those used in writing with crayons.
- Toddlers are developing their language skills, so simple explanations provide a positive environment for development.
- Setting limits helps the child to develop boundaries in relationships and behavior. At the same time, the environment should not be one in which the child is constantly told “No.”

The Preschooler: 3 to 5 Years

The child of 3 to 5 years is preparing to go out into the world.

Physical Development Individual differences, such as heredity, account for differences in height and weight among

EDUCATING THE PATIENT

Keeping Infants and Toddlers Safe

Teaching the parents or caregivers of infants and children about safety may be the responsibility of the medical assistant. Use the following points when teaching parents or caregivers:

- Keep emergency phone numbers close to the phone for the family and sitters.
- Make sure the crib meets federal safety standards.
- Never hold the infant or toddler on your lap in a car. Use an approved car seat placed in the back of the vehicle. Use the current recommendations from the American Academy of Pediatrics (<http://www.aap.org>) for forward-facing or rear-facing infant car seats. (See Figure 40-6.)
- Never leave the child unattended in the car.
- Do not put pillows, comforters, or plush toys in the infant's crib.
- Prevent falls. Place the baby on a low surface and use correctly installed gates across stairs.
- Prevent choking. Check toys for small objects that might come loose. Be sure that clothing does not have cords around the neck.
- Do not leave hanging toys over the crib once the child begins to reach, pull, and roll over.
- Keep all cords on window blinds, lamps, and electrical equipment out of reach.
- Never leave a child unattended around, near, or in any kind of water, including the water in toilets, mop buckets, or pools.

FIGURE 40-6 Infants and toddlers should be in approved car seats. Check the Internet site of the American Academy of Pediatrics for proper type and size.

© Lawrence Lawry/Getty Images RF

- Set the water temperature of the household hot water tank at 120°F. Turn pot handles inward, away from the edge of the stove, while cooking. Cover electrical outlets.
- Keep medicines and chemicals, including household cleaners, out of reach or in locked cabinets. Post the local poison control center's phone number in an accessible location.

children between the ages of 3 and 5 years. During this time, it is best not to compare the preschooler's size to that of another preschooler. Each child's growth should be monitored and compared to the size documented on his or her ongoing growth chart. Girls progress more rapidly toward their adult height and weight than do boys. The respiratory rate and heart rate begin to slow down, coming closer to the adult range. Bones begin to ossify, or harden, between the ages of 2 and 7. During these years, it is important for children to be active in their play. They also need adequate calcium intake for the development of strong bones. Most children will have achieved nighttime bowel and bladder control by the time they are 3 or 4 years of age. If lack of bowel and/or bladder control persists beyond 4 or 5 years, this should be brought to the physician's attention.

During the 3- to 5-year period, many skills are achieved, including going up and down stairs using an alternating step approach, riding a tricycle, skipping, hopping on one foot, and throwing a ball with accuracy. Girls are usually about a year ahead of boys in small muscle coordination and fine-motor skills. A child of 3 can draw simple shapes and use a pencil to imitate the way an adult writes. At 4, the child can draw a simple human figure and can cut with blunt scissors, though not well at this age. A child of 5 can reproduce some shapes,

letters, and numbers. By the age of 5, some children also may have learned how to tie their shoes.

Intellectual-Cognitive Development Language grows by leaps and bounds during these years. The imaginative child of 3 years has a vocabulary of about 900 words, forms simple sentences, and can tell simple stories that may be very "I"-oriented. At 4 years of age, the child's vocabulary is about 1,600 words, sentences are complete, and the favorite question is "Why?" Parents need to give very simple answers such as "Because it will keep you safe right now." The child's vocabulary at age 5 exceeds 2,000 words, and the stories the child tells involve more detail. At this age, the child has learned the difference between telling stories and lying.

Psycho-Emotional Development The 3-year-old child is very easy and pleasant. Children of this age usually enjoy music. A child at this age has an increasing sense of self, but imagination may lead the child to have unfounded worries and fears, especially at night. At 4 years of age, negativity may increase. Parents hear more of the "Nos" that they heard when the child was 2 years old. The 4-year-old child is testing limits and needs guided opportunities for freedom. Once a child reaches 5 years, life settles down a little. The child is more

self-assured, well adjusted, and home-centered. At this age, the child likes to follow the rules, may want to “play by the rules,” and is capable of accepting some responsibility.

Social Development Three-year-old children know what gender they are. The child knows how to take turns and may enjoy brief activities in a group with other children. A 3-year-old child likes to “help.” Four-year-old children are very social and enjoy playing simple group games, like tag and hide-and-seek. At 5 years, the child continues to be very social, enjoys playing with other children, and likes games in which the “rules” are observed.

Aspects of Care: 3 to 5 Years Consider the following when caring for children from 3 to 5 years or providing parent or caregiver education.

- The child of 5 years should receive a complete preschool developmental assessment and physical that includes an evaluation of hearing and vision.
- Immunizations, discussed later, must be up to date when the child enters kindergarten.
- Children of about 3 years may have night terrors. Parents should discuss these with the pediatrician if they are severe or persistent.
- Children may use delaying tactics at bedtime and may need to be shown repeatedly that there is nothing in the closet or under the bed. A nightlight is useful.
- Nighttime routines are important in helping a child feel secure.

The Elementary School Child: 6 to 10 Years

The following describes the stages of development of the 6- to 10-year-old child.

Physical Development During childhood, girls may be taller and heavier than boys. Bones continue to ossify. Permanent teeth replace “baby teeth.” Muscles continue to develop. Regular exercise is needed to encourage strength and coordination. At 9 and 10 years of age, the reproductive system also will be developing.

Intellectual-Cognitive Development Knowledge explosion happens once a child enters school. On entering school, the 6-year-old child has a brief attention span. By 10 years old, she is able to focus for longer periods of time. Most children of this age like to talk. As children move from 5 or 6 years of age toward 9 and 10 years, they are better able to separate fantasy from reality. They develop a sense of what is right and wrong, of honesty and fairness.

Psycho-Emotional Development When children approach 10 years of age, they may be more influenced by their peers than by their parents. During these years, children are beginning to develop a sense of self and learn gender-related roles. Children of 6 to 8 years of age may have trouble thinking about disasters that they hear about. As children

approach 10 years of age, they are better able to grasp concepts of time and distance. A 9- to 10-year-old child may want to do something to help others. School-age children may be very sensitive to criticism and to what they see as failure.

Social Development School is central to the life of a child between 6 and 10 years of age. Although team sports and activities become important, parents need to avoid allowing the child to become overwhelmed with too many organized activities at this time. Children also need time to be quiet and alone. Outdoor activities help to use up some of the child’s energy. Appropriate social behaviors are learned during this stage.

Aspects of Care: 6 to 10 Years Consider the following when caring for 6- to 10-year-olds or providing parent or caregiver education.

- Structure and a schedule help to maintain order and discipline.
- Monitor physical activities to prevent injury. The American Academy of Pediatrics advises against elementary-school-age children participating in contact sports.
- Consistency in daily activities and in discipline helps the child to develop intellectually, emotionally, and socially.
- Regular health and dental care and maintenance of immunizations are required.
- Communicable diseases are common.

The Middle School Child: 11 to 13 Years

The following sections will give you some insight into the stages of development of the 11- to 13-year-old child.

Physical Development In the United States and most other Western cultures, the onset of puberty occurs in females at around 12 or 13 years of age, but some may experience changes as early as 9. **Puberty** refers to the physiological changes that make a person capable of sexual reproduction. By the time a girl reaches middle school, a significant occurrence may be the onset of menstruation. It is important for everyone to remember that even though her body may be maturing, she is still only between 9 and 12 years old. Males tend to go through the changes of puberty later than females (Figure 40-7). The average age for males to experience these changes is around 14 years. Hormonal changes may contribute to development of skin problems and acne.

Intellectual-Cognitive Development Grades may slip during this time. So much physical growth is taking place and so many physiological changes are occurring that less energy is available to concentrate on academics. Preadolescents may tend to exaggerate and “bend the truth.”

Psycho-Emotional Development Although preadolescents crave independence, they are also very unsure of themselves. They are experiencing a wide range of physical changes and, at the same time, are learning the roles of

FIGURE 40-7 Some changes during puberty are the same for males and females. Others are unique to one sex.

sexuality. It is very important for preadolescents to receive accurate information about their changing bodies and feelings from appropriate and reliable sources. Middle-school-age students may not be comfortable asking parents questions about sexuality. Conflict may arise at this time. Parents may find that the preadolescent is easily annoyed and may be temperamental. Frequently, the preadolescent child will take on the behaviors of his or her peer group.

Social Development During the middle school years, children are learning about their own sexual identity and may not be comfortable in heterosexual relationships. Girls express an earlier interest in male-female relationships than do boys. Children of this age need to be able to turn to an adult with whom they are comfortable, so they can ask personal and intimate questions.

Aspects of Care: 11 to 13 Years Consider the following when caring for preadolescents or providing parent or caregiver education.

- A preadolescent needs to be assured that he or she is valued and loved.
- Consistency in discipline is very important.
- Parents should not be hypercritical or make too many demands.
- Friendships and associations should be monitored.
- Overscheduling of the child's time should be avoided.

The Adolescent: 14 to 19 Years

The teen years can be full of excitement for teenagers and their family and friends. They also can be difficult years.

Tremendous physiological changes during this time may cause internal conflicts that can turn into external clashes. Parents may feel anxious about their child's quest for independence and about the child's upcoming departure from the home. The process of developing independence, a personal identity, and future plans is important during this stage.

Physical Development During the later teen years, females attain their adult height and weight. Males may continue to grow in height until 25 years of age. Physical growth and development in the teenage years are centered on normal sexual change. Girls usually have reached **menarche**, the onset of menstruation. Boys may have nocturnal emissions of seminal fluid (also called wet dreams). Weight control can be a concern. Some health problems of adulthood can be traced back to lifelong habits of poor dietary choices and lack of exercise begun in adolescence.

Intellectual-Cognitive Development During the early adolescent years, the child may have taken the word of an adult or a peer without question. Now, the teen asks questions and needs to work out answers that fit into his or her values. Adolescents often do not see the connection between behavior and consequences. This may lead to experimentation with drugs, alcohol, or sex.

Psycho-Emotional Development An adolescent knows the socially acceptable and appropriate ways to express feelings, but the pressures felt by adolescents may result in angry outbursts. Anger that is directed inward can be harmful. Anxiety and sometimes depression are part of adolescence.

Social Development Friendships are very important to adolescents. As teens get older, they become more comfortable with their parents and outgrow the attitude of “not wanting to be seen dead” with their parents. The teen years are wonderful and difficult at the same time. Problems faced by teens include eating disorders, substance abuse, sexually transmitted infection, suicide, and violence. You will examine these special concerns further later in this chapter.

Aspects of Care: 14 to 19 Years Consider the following when caring for teens or providing education to the parents or caregiver.

- Teens need adequate amounts of calcium and weight-bearing exercise for strong bone development.
- Teens should know the risks of early, unplanned pregnancy and sexually transmitted infections when engaging in sexual activity.
- The adolescent needs to spend time enjoying friendships, sporting events, and social events.
- People who are caring for teens should
 - Listen.
 - Give them the facts.
 - Trust them.
 - Provide them with firm and friendly discipline.
 - Be consistent.
 - Educate them with their independence in mind.
 - Set limits and stick to them.
 - Set examples of good behavior and good taste.
 - Remember how it feels to be an adolescent.

► Pediatric Examinations

LO 40.2

Many of the exam procedures for a pediatric patient are the same as those for an adult. While you prepare the child or adolescent for the exam, you may discuss with the parent, caregiver, or child topics such as eating habits, sleep patterns, daily activities, immunization schedules, and toilet training. Discussions should be appropriate for the child’s developmental stage. This discussion will provide important clues to possible abnormal physical, cognitive-intellectual, psycho-emotional, and social development. Additional discussion topics such as sexually transmitted infections, drugs, and alcohol may be appropriate for an adolescent. Point out potential problems to the licensed practitioner.

Some children are afraid of going to the doctor’s office. You can help relieve a child’s fear by calmly explaining procedures before they occur, giving the reason for each procedure and being cheerful and mindful of a child’s feelings. Allowing a child to examine some of the blunt instruments may also lessen fear (Figure 40-8). If a patient is physically resistant to the exam, you may need to call for assistance from the licensed practitioner or caregiver, or the child may need to be restrained.

FIGURE 40-8 Providing a pediatric patient with a diversion may help lessen the child’s fear.

© PhotoAlto/Laurence Mouton/Getty Images

Try to speak in terms aimed at the child’s age level and kneel if necessary to make eye contact with the child. Treat the child with respect and provide positive reinforcement when a child is cooperative. Avoid making light of crying or pain. Make a game out of some aspect of a procedure and provide a small token reward at the end of a visit. For infants, a gentle approach, such as talking quietly and holding them comfortably, is helpful.

Be mindful of adolescents’ sensitivity toward rapid growth and physical, sexual, and social development when you prepare them for examination. Adolescents and preadolescents often feel awkward and self-conscious about being examined. They also may prefer to dress alone and to be alone with the licensed practitioner.

Well-Child Examination

Parents should bring their infants and children to the pediatrician for regular checkups and growth monitoring. The American Academy of Pediatrics (AAP) recommends the following frequency:

- Infants need seven well-baby exams during their first year, at these intervals: 3 to 5 days, 1 month, 2 months, 4 months, 6 months, 9 months, and 1 year.
- Children in the second and third years of life should have checkups at 15, 18, 24, and 30 months.
- From the age of 3, children should have checkups every year.

The AAP has developed recommendations for these examinations. See Table 40-2 for a summary of the components of the well-child examination based on the age of the child.

Follow standard precautions and prepare for the physical exam the same way you would for an adult, except for draping and positioning. Ask the parent of an infant or toddler to remove all the child's clothing except the diaper. Then keep the child covered until the physician enters the exam room. An infant or toddler may be crying during the exam. To assist the physician in hearing chest sounds with a stethoscope, ask the parent to allow the infant to suck on a pacifier, if used, to quiet the crying. Feeding the child during the exam is not encouraged because stomach sounds interfere with clear auscultation (listening to body sounds with a stethoscope). Distracting infants and toddlers with mobiles, shiny surfaces, or toys may help the exam go more smoothly. Review the *Points on Practice* feature Assisting with an Exam for an Infant or Child for additional information about the pediatric exam.

TABLE 40-2 Recommendations for Preventive Pediatric Healthcare*

Developmental Stage	Components of the Examination
Infancy (birth to 12 months)	History and physical Length/height and weight Head circumference Weight for length Immunizations Newborn metabolic/hemoglobin screening Developmental/behavioral assessments
Early childhood (12 months to 4 years)	History and physical Length/height and weight Head circumference up to 24 months Body mass index starting at 24 months Weight for length up to 18 months Blood pressure and vision screening starting at 3 years Hearing starting at 4 years Immunizations Developmental/behavioral assessments
Middle childhood (5 years to 10 years)	History and physical Length/height and weight Body mass index Blood pressure Vision and hearing screening Oral health at 6 years Immunizations
Adolescence (12 years to 21 years)	History and physical Length/height and weight Body mass index Blood pressure Vision and hearing screening Ages 18–21 dyslipidemia screening

POINTS ON PRACTICE

Assisting with an Exam for an Infant or Child

When assisting with an exam for an infant or child, you will need to take some special considerations. The techniques you use to prepare an infant or child emotionally and physically should be modified based on the patient's age and ability.

Emotional

Infants and toddlers are likely to be afraid of you because you are a stranger. Approach these children slowly, smile, and use a gentle voice. Children of preschool age are sometimes uncooperative and challenging. Remain calm, perform the procedures quickly, and restrain the child (with assistance from the parent) when appropriate. To prevent children from getting injured, watch them at all times.

Physical

Base your choice of an exam position for children on each child's age and ability to cooperate. Although young infants are usually examined on an examining table, older infants and toddlers may need to be examined while held on a parent's lap. Some toddlers may cooperate while standing on the examining table with a parent nearby. Some children may need to be restrained during parts of the examination or during an immunization. See Figure 40-9. Preschool children can usually be placed on the examining table if a parent is nearby. Regardless of their position, watch children at all times to prevent injury. When examining young children, licensed practitioners typically perform percussion (tapping on the surface to hear the underlying structures) and auscultation (listening) first, because children are more likely to be calm and quiet at the outset. Practitioners always examine painful areas last. Practitioners may examine older children's genitalia last because, after a certain age, children tend to find such an exam embarrassing.

FIGURE 40-9 By fully immobilizing the child, you decrease the risk that his or her movement will result in injury.

► Pediatric Immunizations

LO 40.3

As discussed in the *Infection Control Fundamentals* chapter, you should know that one of the necessary elements in the cycle of infection is the transmission of the pathogen to a susceptible host. To reduce the susceptibility of the host to infection, **immunizations** are given. An immunization is the administration of a vaccine to protect susceptible individuals from infectious diseases. When a healthy patient is vaccinated with a weakened strain of a virus, the patient's lymphocytes manufacture antibodies against that virus. These antibodies remain in the body, making it immune to that virus in the future. In general, there are two types of vaccines: live-attenuated and inactivated. Live-attenuated vaccines are a weakened form of the virus itself. Inactivated vaccines are either whole viruses, whole bacteria, or fractions of either. Inactivated vaccines usually require multiple doses for immunity to occur.

Immunizations are usually given during regular checkups (Figure 40-10). Immunizing children against diseases such as hepatitis B, diphtheria, tetanus, pertussis (whooping cough), poliomyelitis, measles, mumps, rubella (German measles), chickenpox, human papillomavirus (HPV), rotavirus, meningococcal disease, and *Haemophilus influenzae* type B (Hib) is recommended. Many vaccines have largely eliminated the threat of these once-prevalent, life-threatening diseases.

The first vaccine, for hepatitis B, is given to a newborn the day after birth. Some vaccines require a series of doses to give immunity. Booster doses may be required for a particular vaccine at a later age. The Centers for Disease Control and Prevention (CDC) recommends that physicians take every reasonable opportunity to vaccinate a child, to ensure that the child receives the protection he needs. If a child gets behind on his immunizations, a catch-up schedule is available.

As a medical assistant, you will play a vital role in the immunization process. Your duties may include

- Scheduling appointments and follow-up visits at the appropriate time based on the immunization schedule.
- Educating parents about the benefits and risks of vaccines and obtaining informed consent.
- Administering the vaccine correctly.

FIGURE 40-10 Immunizations are part of routine well-child visits in a pediatric practice.

© BSIP SA/Alamy Stock Photo

- Keeping careful immunization records, including the vaccine type, the date of vaccination, and the vaccine lot number.
- Ensuring proper vaccine storage and handling, including checking the temperature of the refrigerator and freezer daily.

Immunization Recommendations

The Advisory Committee on Immunization Practices, the American Academy of Pediatrics, and the American Academy of Family Physicians jointly publish immunization schedules for children. When working in a pediatrician's office, you should be familiar with the current vaccination schedule guidelines because they change occasionally. New guidelines, methods, and vaccines are constantly being developed. See Figure 40-11 for the birth to age 6 and the ages 7–18 immunization schedules. If you are responsible for administering immunizations, you should stay current with the most recent information found online at <http://www.cdc.gov/vaccines/schedules/hcp/imz/child-adolescent.html>.

Informed Consent

The licensed practitioner may ask you to explain the benefits and risks of an immunization to the parents. You will need to explain that the side effects of immunizations are usually mild, such as a slight fever or soreness, and of short duration. Review with the parent the vaccine information statement for the specific immunization you will be administering (Figure 40-12). Advise parents that the benefits of immunity greatly outweigh the risks. Then obtain informed consent for the child's immunization. Provide a copy of the vaccine information statement and then have the parent sign so the immunization can be given. Remember that religious or other personal beliefs may prevent parents from consenting to immunizations for their child. Some parents may want to delay or slow down the number of immunizations given at one time. Give immunizations as ordered and record all appropriate information in the patient's chart.

Administering Immunizations

In many states, medical assistants may administer immunizations. Most immunizations are given as injections. You might be required to give more than two vaccinations in a single visit. Careful site selection is important when giving multiple injections. Refer to the *Medication Administration* chapter for information about administering various types of injections and selecting an appropriate injection site. Some vaccines, such as live polio, are given orally. Most vaccinations may be administered even if the child has a mild illness. The physician will make the decision to vaccinate a child who is ill based on the disease and the severity of the symptoms. For the most part, if a child has a fever, the physician may postpone the immunization until the fever has subsided. However, do not postpone the visit if the child has an upper respiratory infection without a fever. Remember that the child does not need to restart a series of immunizations. He can simply receive the next scheduled immunization as soon as possible.

Figure 1. Recommended immunization schedule for persons aged 0 through 18 years – United States, 2015.

These recommendations must be read with the footnotes that follow. For those who fall behind or start late, provide catch-up vaccination at the earliest opportunity as indicated by the green bars in Figure 1. To determine minimum intervals between doses, see the catch-up schedule. School entry and adolescent vaccine age groups are shaded.

This schedule includes recommendations in effect as of January 1, 2015. Any dose not administered at the recommended age should be administered at a subsequent visit, when indicated and feasible. The use of a combination vaccine generally is preferred over separate injections of its equivalent component vaccines. Vaccination providers should consult the relevant Advisory Committee on Immunization Practices (ACIP) statement for detailed recommendations, available online at <http://www.cdc.gov/vaccines/hcp/acip-recs/index.html>. Clinically significant adverse events that follow vaccination should be reported to the Vaccine Adverse Event Reporting System (VAERS) online (<http://www.vaers.hhs.gov>) or by telephone (800-822-7967). Suspected cases of vaccine-preventable diseases should be reported to the state or local health department. Additional information, including precautions and contraindications for vaccination, is available from CDC online (<http://www.cdc.gov/vaccines/recs/vac-admin/contraindications.htm>) or by telephone (800-CDC-INFO [800-232-4636]).

This schedule is approved by the Advisory Committee on Immunization Practices (<http://www.cdc.gov/vaccines/acip>), the American Academy of Pediatrics (<http://www.aap.org>), the American Academy of Family Physicians (<http://www.aafp.org>), and the American College of Obstetricians and Gynecologists (<http://www.acog.org>).

FIGURE 40-11 Recommended immunization schedules for birth to 18 years. For more detail and the most current information, check the Centers for Disease Control and Prevention website.

Before administering a childhood immunization, check for any contraindications to its use. A **contraindication** is a known risk or reason not to give the immunization. For example, pertussis vaccine must not be given to a child with a progressive neurologic disorder. It also must not be administered to a child who developed seizures, persistent crying, or a high fever after receiving a previous pertussis vaccine. In such a situation, the doctor would direct you to administer diphtheria and tetanus toxoids instead of the diphtheria and tetanus toxoid and pertussis vaccine (DTaP).

Immunization Records

Under the National Childhood Vaccine Injury Act of 1988, you must record certain information about immunizations in a child's permanent medical record. Required information includes

- The vaccine's type, manufacturer, and lot number.
- The date on the vaccine information statement and the day and time the statement was given to the parent.
- The date of administration.

- The name, address, and title of the healthcare professional who administered the vaccine.

You also must document the vaccine type using standard abbreviations. For combination vaccines, such as Pediarix™, you record the vaccine under all three components: DTaP, IPV, and hepatitis B. In addition, you must document

- The administration site, route, and dosage.
- The vaccine's expiration date.

Parents should maintain an accurate, up-to-date immunization record for each child. They should be encouraged to bring this record with them to each healthcare visit. Each state and/or the CDC issues an immunization record form, which may be available in languages other than English. Complete a form after each child's first immunization. Instruct the parents to keep the form and bring it with the child for each subsequent immunization so that you can update the record. The immunization record for Chris Matthews, our case study patient, is shown in Figure 40-13. Advise parents that this record is important to keep because it acts as proof of immunization,

DIPHTHERIA TETANUS & PERTUSSIS **VACCINES**

WHAT YOU NEED TO KNOW

Many Vaccine Information Statements are available in Spanish and other languages. See <http://www.immunize.org/vis>.

1. Why get vaccinated?

Diphtheria, tetanus, and pertussis are serious diseases caused by bacteria. Diphtheria and pertussis are spread from person to person. Tetanus enters the body through cuts or wounds.

DIPHTHERIA causes a thick covering in the back of the throat.

- It can lead to breathing problems, paralysis, heart failure, and even death.

TETANUS (Lockjaw) causes painful tightening of the muscles, usually all over the body.

- It can lead to “locking” of the jaw so the victim cannot open his mouth or swallow. Tetanus leads to death in up to 2 out of 10 cases.

PERTUSSIS (Whooping Cough) causes coughing spells so bad that it is hard for infants to eat, drink, or breathe. These spells can last for weeks.

- It can lead to pneumonia, seizures (jerking and staring spells), brain damage, and death.

Diphtheria, tetanus, and pertussis vaccine (DTaP) can help prevent these diseases. Most children who are vaccinated with DTaP will be protected throughout childhood. Many more children would get these diseases if we stopped vaccinating.

DTaP is a safer version of an older vaccine called DTP. DTP is no longer used in the United States.

2. Who should get DTaP vaccine and when?

Children should get 5 doses of DTaP vaccine, 1 dose at each of the following ages:

- 2 months ■ 4 months ■ 6 months
- 15–18 months ■ 4–6 years

DTaP may be given at the same time as other vaccines.

3. Some children should not get DTaP vaccine or should wait.

- Children with minor illnesses, such as a cold, may be vaccinated. But children who are moderately or severely ill should usually wait until they recover before getting DTaP vaccine.
- Any child who had a life-threatening allergic reaction after a dose of DTaP should not get another dose.
- Any child who suffered a brain or nervous system disease within 7 days after a dose of DTaP should not get another dose.
- Talk with your doctor if your child:
 - had a seizure or collapsed after a dose of DTaP,
 - cried non-stop for 3 hours or more after a dose of DTaP,
 - had a fever over 105°F after a dose of DTaP.

Ask your healthcare provider for more information. Some of these children should not get another dose of pertussis vaccine but may get a vaccine without pertussis, called **DT**.

4. Older children and adults

DTaP is not licensed for adolescents, adults, or children 7 years of age and older.

But older people still need protection. A vaccine called **Tdap** is similar to DTaP. A single dose of Tdap is recommended for people 11 through 64 years of age. Another vaccine, called **Td**, protects against tetanus and diphtheria, but not pertussis. It is recommended every 10 years. There are separate Vaccine Information Statements for these vaccines.

Diphtheria/Tetanus/Pertussis

5/17/2007

FIGURE 40-12 Review the vaccine information sheet with the parent and obtain a signature before administering a vaccine.

which may be required by day care centers, schools, the military, and other organizations. This record also may be helpful when parents consult another doctor, in case of emergency, or when moving to a new location.

Vaccine Storage and Handling

Vaccines must be stored properly. As a medical assistant, in order to ensure vaccine safety and effectiveness, you are responsible for proper storage and handling from the time a vaccine arrives at your facility until it is administered to the patient. Follow these general guidelines.

- Store vaccines at the recommended temperatures immediately upon arrival at your facility. Check and record

temperatures of refrigerators and freezers daily. If the correct temperature is not maintained, the vaccine will lose its effectiveness. Live-attenuated virus vaccines are especially sensitive to heat.

- Store refrigerated vaccines between 35°F and 46°F (2°C and 8°C).
- Store frozen vaccines between –58°F and +5°F (–50°C and –15°C).
- Rotate your supply of vaccines so those with the shortest expiration date are used first. Place the vaccine with the longest expiration date behind the vaccine that will expire the soonest. Remove expired vaccines from usable stock immediately.

- Follow infection control guidelines when preparing and administering vaccines.

Pediatric Screening and Diagnostic Tests

LO 40.4

Pediatricians look for any sign of growth abnormality during routine well-child visits. Physicians compare a child's physical, cognitive-intellectual, psycho-emotional, and social signs to charts showing national averages. In general, physicians look for signs that the child is in the appropriate stage of growth for her age. The medical assistant's role in pediatric exams is similar to the role in adult patient exams.

During the pediatric exam, the medical assistant may assist with or perform many tasks, including taking vital signs and body measurements, performing vision and hearing tests, collecting specimens, and administering medications and immunizations.

Vital Signs

Some variations in technique and results should be considered when performing vital signs on pediatric patients. In addition to the normal vital signs range variations (review Table 37-1 from the *Vital Signs and Measurements* chapter), some other things should be taken into account. Taking a child's or an infant's temperature can be a challenge. If the infant or child is likely to cry or become agitated, take the temperature last. Measure pulse, respiration, and blood

pressure (if ordered) before you take the temperature to avoid having these measurements elevated because of the child's agitation. Oral thermometers are not appropriate for children younger than 5 years of age because these children are too young to safely hold the thermometer in their mouths. Instead, take axillary, rectal, tympanic, or temporal temperatures. If you use a rectal thermometer, hold it in place until the temperature registers to prevent the thermometer from being expelled or injuring the patient. Tympanic and temporal thermometers are especially useful in pediatric offices because of their speed and safety.

Blood pressure in children or infants is not routinely measured at each visit. Instead, the measurement is taken per the doctor's orders. The procedure is the same as that for taking blood pressure in adults, except for these modifications:

1. Ideally, take the patient's blood pressure before performing other tests or procedures that may cause anxiety. In this way, you can avoid a falsely high result.
2. Be sure to use the correct cuff size for the child or infant. The bladder width should not exceed two-thirds the length of the upper or lower arm. The bladder should cover three-fourths of the extremity's circumference.
3. Do not attempt to estimate an infant's blood pressure using the palpatory method (discussed in the *Vital Signs and Measurements* chapter). It is typically not used.
4. Inflate the pressure cuff to 20 mmHg above the point at which the radial pulse disappears.
5. Deflate the cuff at a rate of 2 mmHg per second.
6. You may continue to hear a heartbeat on a child or infant until the pressure reaches zero, so note when the strong heartbeat becomes muffled.

Body Measurements

Children and infants are weighed and measured at each office visit. Children who can stand may be weighed on an adult scale. If toddlers cannot remain still on an adult scale, weight may be determined by weighing an adult holding the toddler, then subtracting the adult's weight. Infants are weighed on infant scales, which typically measure pounds and ounces. Infant scales are sometimes built into a pediatric examining table.

The height of children and the length of infants are measured at each office visit. Measure children in the same manner as you measure an adult. Some offices are equipped with height bars or wall charts that are separate from a scale. Use these devices in the same way as those attached to a scale. Measure infants while they are lying down; in this instance, you are measuring length instead of height. Some pediatric examining tables have a built-in bar for measuring length. You also can use a tape measure or yardstick.

The circumference of an infant's head is an important measure of growth and development and is used to evaluate diseases such as hydrocephalus or excessive cerebrospinal fluid in the cranial cavity, which causes enlargement of the head. You may be asked to perform or assist with this measurement

FIGURE 40-14 The medical assistant uses a flexible tape to measure the circumference of an infant's head.

© CMSP/Getty Images RF

when you measure the infant's length. Measurement of head circumference may be performed at the same time as weight and length, or it may be part of the general physical exam (Figure 40-14). The steps for measuring infants are described in Procedure 40-1, at the end of this chapter. Review the *Vital Signs and Measurements* chapter and the procedures for weighing and measuring children.

General Eye and Vision Exam

As part of the general exam, the pediatrician examines the interior of the child's eyes with an instrument called an *ophthalmoscope*. You will probably perform the visual acuity test (Figure 40-15). Make a game of covering the child's eye if the child resists this part of the procedure. Use a pediatric vision chart as shown in Figure 40-16 for patients who cannot read. If the caregiver brought the child in specifically for a vision test, record in the child's chart whatever symptoms the caregiver mentions. Follow the procedure in the *Assisting with Eye and Ear Care* chapter and use these modifications when performing vision screening on a pediatric patient:

- Watch for signs of visual difficulty during the test, such as tilting the head in a certain direction, blinking, squinting,

FIGURE 40-15 Making a game out of the visual acuity test helps put a child at ease.

© Ken Lax

or frowning. Observe the child for eyes that are misaligned or don't focus together. Keep in mind that some vision problems may have no warning signs. For example, amblyopia, or lazy eye, is a fairly common eye problem (affecting about 2 out of 100 children) that develops when a child has one eye that doesn't see well or is injured and he begins to use the other eye almost exclusively. The problem must be detected by the age of 3 in order to treat and restore normal vision in the affected eye by age 6. If this situation persists for too long (past 7 to 9 years of age), vision may be lost permanently in the unused eye.

- Use a pointer to select one symbol at a time in random order to prevent patients from memorizing the order.
- It is common to start with children at the 40- or 30-foot line or larger if low vision is suspected and then proceed to the 20-foot line.
- Note the smallest line on which the child can identify three out of four or four out of six symbols correctly.

General Ear and Hearing Exam

A pediatric ear exam is important because so many children have ear infections or upper respiratory infections involving the ear. Because children's eustachian tubes are more horizontal than those of adults, fluid collects more easily in the tubes and can promote bacterial growth. The tubes are also short and connected to the throat, making it easy for any upper respiratory infections to travel to the ear.

You may be asked to perform a hearing test on a pediatric patient. Use the procedure found in the *Assisting with Eye and Ear Care* chapter. When performing a hearing test on an infant or toddler, follow these general guidelines:

1. Have the patient sit, lie down, or be held by the parent in a quiet location.
2. Instruct the parent to be silent during the procedure.
3. Position yourself so that your hands are behind the child's right ear and out of sight.

FIGURE 40-16 A kindergarten test chart is used to check the vision of a child who cannot read.

Reprinted with permission of Richmond Products, Inc.

4. Clap your hands loudly. You also may use a device such as a rattle or clicker to generate sounds of varying loudness. Observe the child's response. (Never clap or create noise directly in front of the ear because this can damage the eardrum.)
5. Record the child's response as positive or negative for loud noise.
6. Position one hand behind the child's right ear, as before.
7. Snap your fingers or make a softer noise using a device. Observe the child's response.
8. Record the response as positive or negative for moderate noise.
9. Repeat the steps for the left ear and record all results.

Diagnostic Testing

Diagnostic procedures on adults, such as X-rays, blood and urine tests, and throat cultures, are also used for children. The pediatrician basically uses the same laboratory tests and radiologic tests. He performs some diagnostic tests in the office and needs the same types of specimens. Throat cultures, urine, and blood specimens are collected with a few extra considerations, explained in the following paragraphs.

Throat Culture Because streptococcal infection can be especially serious in a child, some pediatricians perform a rapid test for the presence of streptococcal bacteria so that they can immediately start the appropriate medical treatment. If the test is positive, the licensed practitioner begins treatment with antibiotics specifically for this type of bacterium. Whether the test is positive or negative, the practitioner may also do a throat culture. A throat culture can determine which of the streptococcal bacteria are present or whether other organisms are causing the symptoms. The results can indicate a possible change in medication. Review the method for obtaining a throat culture in the Obtaining a Throat Culture Specimen procedure in the chapter *Microbiology and Disease*. Having a small child lie down rather than sit may make the process easier. If the child refuses to open the mouth, gently squeeze the nostrils shut. The child will eventually open the mouth to breathe. Enlist the parent's help to restrain the child's hands if necessary.

Pediatric Urine Specimen When you collect a urine specimen from a pediatric patient, involve the child (if age-appropriate) and the parents or guardians. Explain the procedure thoroughly and ask specific questions, including the following:

- If the child is in diapers, ask whether there is a problem of persistent diaper rash. (Rash may indicate a change in urine composition because of renal dysfunction.)
- Is the child excessively thirsty? (In this case, the patient may not be taking in enough fluids for the amount of urine being excreted. Excessive thirst, combined with increased urinary frequency and volume, is symptomatic of diabetes.)
- Has the child experienced any difficulty urinating or a urine stream change? (These signs may suggest an obstruction in the urinary tract.)
- Does the child cry when urinating? (If so, the child may have pain or burning on urination, which can indicate a urinary tract infection.)
- If the child is in diapers, ask how many diapers are wet each day. Has the number changed recently? (Responses to these questions can rule out or confirm a urine volume change. For example, a child with a fever and increased perspiration might experience decreased urine volume.)
- Has the child experienced deterioration in bladder control, such as bed-wetting (**enuresis**)? (The child may be under stress or may have a small bladder capacity or a urinary tract infection.)
- If the child is having problems with toilet training and is older than 4 years old, ask whether the child learned to

sit, stand, and talk at the age-appropriate times. (If so, the child may have a urinary system dysfunction.)

When you collect a urine specimen from a child who is toilet-trained, follow the same procedures as for an adult. If the child is an infant or not toilet-trained, however, follow the steps outlined in Procedure 40-3, at the end of this chapter, and shown in Figure 40-17. The *Collecting, Processing, and Testing Urine and Stool Specimens* chapter provides additional information.

Blood-Drawing Procedures and Children Collecting blood may be part of your responsibility in a pediatric office. The *Collecting, Processing, and Testing Blood Specimens* chapter provides detailed information about this task. Note that when working with children, it is a challenge to explain blood-drawing procedures to them, and that many children become visibly upset by the situation. If possible, it is best to talk with the parents or caregivers before working with the child. The adults can provide the best insight into how their child handles stressful situations.

Your primary concern when working with infants is to complete tests accurately. Because an infant's veins are often too small for adequate blood collection, the best site for drawing blood is usually the heel, using a dermal puncture.

When working with children, address them directly. Speak clearly in a calm, soothing voice and explain the procedure briefly in terms they can understand. If they ask whether the process will hurt, be honest. A parent, guardian, or coworker should hold a very young child during a venipuncture or dermal puncture to prevent the child from moving. If a child is extremely distressed, it may be best to go on to another patient while the child calms down.

After you have begun the procedure, give the child status reports, such as "We're almost finished!" and make comments like "You've been very brave." This also helps to calm nervous parents or caregivers. When the procedure is complete, offer a compliment on some aspect of the child's behavior. Gather your supplies and samples as quickly as possible to avoid alarming the child with the sight of blood-collection tubes. If parents or caregivers have questions, encourage them to discuss the tests with the child's physician.

FIGURE 40-17 When you apply a pediatric urine bag, make sure there are no leaks. Follow the steps in Procedure 40-3, at the end of this chapter.

► Pediatric Diseases and Disorders LO 40.5

Many common disorders found in children are not specific diseases. Upper respiratory infections, including colds and viral influenza, occur frequently among children. Do not make assumptions regarding diagnosis or treatment. When reported symptoms include fever, sore throat, runny nose, and earache, any number of conditions could be the cause. Encourage the parent to bring the child to the office. You should, however, tell the doctor as soon as possible when a child has an extremely high fever. The doctor may want the child to go to an emergency room. Do not recommend aspirin for fever in children, as aspirin use in children has been associated with Reye syndrome, a potentially fatal disease of the central nervous system (CNS) and liver. Acetaminophen (Tylenol®) or ibuprofen (Motrin®) is preferred for treating fever in children. However, you should check with the doctor before recommending any fever-reducing medication such as Tylenol® or Motrin®.

Common Diseases and Disorders

When you work in a pediatric office, you should know the signs and symptoms of childhood diseases. These include infectious diseases such as chickenpox, influenza, croup, measles, mumps, pertussis, rubella, scarlet fever, and tetanus, which are discussed in the *Microbiology and Disease* chapter. In addition to infectious diseases, there are several other common diseases of childhood, which are outlined in Table 40-3.

Less Common Diseases and Disorders

Some less common diseases and disorders also can be found in children. You need to be aware of the basic symptoms and the treatments for these disorders.

AIDS Most childhood cases of human immunodeficiency virus (HIV) infection are transmitted from a mother to her infant. The transmission of HIV from an HIV-positive mother to her child during pregnancy, labor, delivery, or breast-feeding is called mother-to-child (*vertical*) transmission. In the absence of any interventions, transmission rates range from 15% to 45%. This rate can be reduced to levels below 5% with effective interventions. All babies born to HIV-positive mothers have HIV antibodies that are detectable through testing at birth. The antibodies persist for a period of 15 to 18 months, but not all of these babies remain permanently infected. AIDS has no cure, but treating the pregnant woman and newborn child with antiviral agents has been shown to lower the rate of HIV infection in the child.

Juvenile Rheumatoid Arthritis Juvenile rheumatoid arthritis (JRA) is an autoimmune disease of the joints that occurs in children aged 16 or younger. The symptoms of JRA include swelling, pain, and stiffness of the joints. The most common type of JRA affects four or fewer joints, typically the large joints such as the knees. A less common form of JRA affects five or more joints, most commonly the small joints of the hands and feet. The severity of the disease ranges from mild to severe and may affect the eyes and internal organs. A child with JRA will have periods of remission (a lessening of symptoms)

and flare-up (a worsening of symptoms). JRA is diagnosed based on the severity of symptoms, specific laboratory tests, and X-rays. Treatment of this disease includes nonsteroidal anti-inflammatory drugs (NSAIDs), disease-modifying anti-rheumatic drugs (DMARDs), corticosteroids, biologic agents, and physical therapy.

As a medical assistant, your role in caring for children with JRA includes emphasizing the value of exercise and physical therapy, stressing the importance of taking medications as directed, and offering assistance by providing patient education brochures and information about local support groups and organizations.

Attention Deficit Hyperactivity Disorder and Learning Disabilities

Attention deficit hyperactivity disorder (ADHD) and learning disabilities (LD) are found in children, adolescents, and adults. These disorders can cause gross motor disability, inability to read or write, hyperactivity, distractibility, impulsiveness, and generally disruptive behavior. ADHD encompasses all conditions formerly identified as hyperactivity, or hyperkinesis, and attention deficit. LD encompasses a wide range of conditions that interfere with learning, including dyslexia (reading problems), dysgraphia (writing problems), and dyscalculia (math problems).

ADHD is misunderstood, misdiagnosed, and overdiagnosed in children. Some physicians fail to recognize ADHD as a cause of academic, social, and emotional problems. Others are quick to attribute too many such problems to ADHD. When ADHD is the correct diagnosis, methylphenidate hydrochloride (Ritalin®) and other drugs may alleviate the symptoms, but not without risk of adverse effects, such as insomnia, increased heart rate and blood pressure, and interference with growth rate. Successful treatment usually requires a combination of drug and behavioral therapies and educational, psychological, and emotional support tailored to the child.

Cerebral Palsy Cerebral palsy, a birth-related disorder of the nerves and muscles, is the most frequent crippling disease in children. It is caused by brain damage that occurs before, during, or shortly after birth or in early childhood. Signs of spastic cerebral palsy (the most common form) include hyperactive tendon reflexes, rapid alteration between muscular contraction and relaxation, permanent muscle shortening, and underdevelopment of extremities. Among people who have this disease, 40% are mentally retarded, 25% have seizures, and 80% have impaired speech. There is no known cure, but the effects of the disorder can be alleviated with physical therapy, speech therapy, orthopedic surgery, splints, skeletal muscle relaxants, and anticonvulsant medication.

Congenital Heart Disease Congenital heart disease is caused by a cardiovascular malformation in the fetus before birth. If the fetus survives, the newborn is usually small. The defect may be so small, however, that it may not be recognized until days, months, or even years later. Some patients have such a mild case of the disease that no treatment is necessary. Others require only low-risk surgery. In still others,

TABLE 40-3 Common Pediatric Diseases and Disorders

Condition	Description	Treatment
Asthma	Inflammation of the airways caused by triggers such as animals (hair or dander), dust, mold, pollen, tobacco smoke, exercise, strong emotions, and viral infection. Symptoms include tightness in the chest, chest retractions, shortness of breath, rapid breathing, and tiredness.	Avoidance of known triggers; measuring of peak flow to determine breathing function; inhaled medications for long-term treatment, including corticosteroids and leukotriene; for quick relief of symptoms, albuterol or Atrovent; allergy shots and oral medications
Head lice	Small insects easily spread among children by head-to-head contact and by sharing objects such as combs and hairbrushes. Lice live on the scalp and lay eggs strongly attached to hair shafts; symptoms include itchy scalp. Identify this condition by locating crawling lice or nits (eggs) attached to hair; examine parted hair carefully at the scalp and bottom of hair strands.	Anti-lice shampoo or 1% permethrin cream rinse; removal of eggs with fine-tooth comb; disinfection of clothing, bedding, and washable toys by machine washing and drying in hot cycles or by dry cleaning; tight bagging for 30 days of items that cannot be washed; disinfection of combs and brushes (used for hair) by washing in anti-lice shampoo
Herpes simplex virus (HSV)	The virus causes cold sore blisters on or near the mouth; diagnosis is made by inspecting lesions. The first stage (2–12 days before appearance of blister) involves tingling and itching sensations; later, the blister ruptures and forms a yellow crust. An outbreak takes about 3 weeks to heal completely.	Application of ice cube to blister, which may promote faster healing; ointments to alleviate cracking and discomfort; avoidance of sun exposure because it may trigger an outbreak
Impetigo	Highly contagious dermatologic disease caused by staphylococcal, or sometimes streptococcal, bacteria; transmitted by direct contact. Causes inflammation and pustules, which are small, lymph-filled bumps that rupture and become encrusted before healing; frequently seen around the mouth and nostrils.	Avoidance of scratching lesions and sharing utensils, towels, bed linens, or bath or pool water that could cause further transmission; careful washing of affected areas two or three times per day to keep lesions clean and dry; topical antibacterial cream
Infectious conjunctivitis (“pink eye”)	Highly contagious streptococcal or staphylococcal bacterial infection of the conjunctiva of the eye; transmitted by direct contact. Causes redness, pain, swelling, and discharge; usually begins in one eye and spreads to other.	Avoidance of scratching eyes and sharing utensils, towels, or bed linens that could cause further transmission; warm compresses to relieve discomfort; antibiotic drops or ointment
Pinworms	Parasites transmitted by swallowing worm eggs, by touching something that the infected person has touched, or by putting infested sand or dirt into mouth. When the eggs hatch in the body, worms attach to intestinal lining; mature females travel to areas just outside the rectum to lay eggs, which causes itching.	Medication given to the whole family to treat and prevent further infestation
Ringworm	Contagious fungal infection of the scalp, groin, feet, or other areas of body, causing flat, dry, and scaly or moist and crusty lesions; lesions develop into a clear center with an outer ring. When the scalp is affected, may cause bald patches.	Oral and topical antifungal medication; isolation to prevent spreading; frequent changing of towels and bedding, with no sharing with others in family; caution that the child should not use others’ combs or brushes
Scarlet fever (“scarlatina”)	Red rash that starts as patches then turns to fine bumps. Occurs either before symptoms or up to 7 days after. Symptoms includes fever, sore throat, chills, vomiting, and abdominal pain.	Antibiotics to clear up the symptoms and to prevent long-term health problems such as rheumatic fever or kidney disease
Streptococcal sore throat (“strep throat”)	Contagious disease spread by droplet. Symptoms include headache, high fever, vomiting, and extremely painful, swollen, and red or white sore throat; causes difficulty swallowing. Complications include progression to rheumatic fever (with arthritis, nephritis, and inflammation of the inner lining of heart).	Streptococci-specific antibiotics given as soon as possible; therapy based on the practitioner’s experience is sometimes given without confirmed diagnosis; antibiotics are adjusted with confirmation of infecting organism; possible hospitalization in acute cases

major high-risk surgery is necessary. Many patients diagnosed with the problem are treated with antibiotics to avoid secondary infections.

A cardiovascular defect can be caused by genetic mutations (changes in the genes), maternal infections (such as rubella or cytomegalovirus), maternal alcoholism, or maternal insulin-dependent diabetes. Blue lips and fingernails—signs

of cyanosis in a newborn—are obvious indications of a cardiac defect.

Down Syndrome Down syndrome is a congenital disorder resulting from one extra chromosome in each of the millions of cells formed during development of the fetus. It is the most common chromosomal abnormality in humans, and it

FIGURE 40-18 A child with Down syndrome usually has distinct facial features.

© Rhea Anna/Getty Images

is not caused by any parental behavior, such as diet or activity. The estimated risk for a Down syndrome birth increases, however, as maternal age increases. Down syndrome is characterized by low muscle tone, which can be alleviated with physical therapy. Characteristic facial features are also evident (Figure 40-18). These include broad face, flattened nasal bridge, narrow nasal passages (increasing the risk of congestion), slanting eyes (vision problems are common), and small teeth and ears. Mild to severe impaired intellectual disability is also a characteristic of Down syndrome.

Hepatitis B Infection with the hepatitis B virus (HBV) can lead to a serious and chronic liver infection. A child can carry the virus for years and only later develop liver failure or liver cancer. The virus can be transmitted across the placenta or during birth if the mother is infected. The disease also may be transmitted sexually, by blood transfusion, or by direct contact. It is frequently seen among drug abusers who share needles. Immunization is available, and children should be immunized starting the day after birth. Children who have not been immunized should begin to receive the series of immunizations for protection from infection.

Respiratory Syncytial Virus The respiratory syncytial virus (RSV) is a major cause of lower respiratory disease in infants and young children. RSV is most often seen in the winter and spring as outbreaks of pneumonia, bronchiolitis, and tracheobronchitis. It is highly contagious, and reinfection is common. Treatment is difficult because the infection is viral rather than bacterial. Antibiotics are thus effective for treating only the possible secondary infections that develop during or after contracting RSV. You may be asked to obtain nasal smears to assist in the diagnosis of RSV. More information about collecting specimens is found in the *Microbiology and Disease* chapter.

Sudden Infant Death Syndrome Sudden infant death syndrome (SIDS) is the sudden death of an infant, which occurs during sleep, that remains unexplained after all possible causes have been carefully ruled out. Most SIDS cases occur between

2 and 4 months of age. Victims appear to be healthy and are more likely to be male than female. When necessary, recommend and refer families to support groups that are helpful to the parents of a SIDS infant. The American SIDS Institute provides this advice as well as family support for victims of SIDS. Counseling and information are also available through local health organizations. Placing the infant on his back to sleep is highly recommended to help prevent SIDS. Other things that can be done to reduce the risk of SIDS include

- Obtain good prenatal care.
- Do not smoke, drink, or take drugs when pregnant.
- Avoid pregnancy during the teenage years.
- Wait at least 1 year between pregnancies.
- Use a firm mattress and avoid covers, toys, pillows, and bumper pads.
- Keep the baby's crib in the parent's room until the baby is 6 months old, or use a monitor.
- Do not let babies sleep in adult beds.
- Do not overheat the infant with covers or clothing while sleeping.
- Avoid exposing the baby to smoke.
- Breast-feed whenever possible.
- Avoid exposure to people with respiratory infections; wash hands and clean anything that comes in contact with the baby.
- Offer the baby a pacifier.

Spina Bifida Spina bifida is a defect of spinal development that occurs during the first trimester of pregnancy. The tissues and bones around the spinal cord do not form correctly or close properly. Neurologic symptoms are common because the spinal cord is not fully protected by the spine's bony and connective tissues. These symptoms may vary with the defect's severity, ranging from foot weakness and bladder or bowel problems to paralysis of the lower extremities and mental retardation. In less severe cases the skin over the spinal cord often has a depression, tuft of hair, or port wine stain. In more severe cases, the newborn has a sac sticking out of the mid to lower back (Figure 40-19).

The treatment and outcome of spina bifida are based on the extent of damage. Surgical closure or implants are sometimes required. Unfortunately, the neurologic conditions cannot be reversed. However, some research has indicated that taking folic acid while trying to get pregnant and during the first trimester of pregnancy may reduce the risk of spina bifida.

Viral Gastroenteritis Gastroenteritis is an inflammation of the stomach and intestines that is caused by a virus. Gastroenteritis caused by a virus may be called the flu, traveler's diarrhea, or food poisoning. Viral gastroenteritis usually subsides within 1 to 2 days. It can be serious in young children, however, because it can cause extreme fluid loss that results in dehydration and electrolyte imbalances.

Symptoms include fever, nausea, abdominal cramping, diarrhea, and vomiting. Gastroenteritis is treated with bed

FIGURE 40-19 Spina bifida occurs when the tissue around the spinal cord does not develop completely. It can be mild, with no symptoms, or severe, causing neurologic symptoms such as paralysis of the lower extremities.

© Phototake

rest, increased fluid intake, dietary modifications (usually only clear liquids), and medication for vomiting and diarrhea if necessary. Antibiotics may be prescribed if evidence of bacterial involvement is present.

► Pediatric Patient Special Concerns

LO 40.6

In addition to well-child exams, immunizations, and the diseases discussed in the previous sections, there are some special concerns for pediatric patients. Medical assistants should be aware of problems such as child abuse or neglect; eating disorders; depression, substance abuse, and addiction; violence; suicide; sexually transmitted infections; and unwanted pregnancies.

Detecting Child Abuse or Neglect

Child abuse is an all-too-common and potentially fatal problem. It frequently goes unnoticed. Whenever a child comes to the office, you should watch for any signs of serious problems in the relationship between the parent or caregiver and the child. Also notice any signs of physical injury, such as unexplained bruises or burns. Any suspicious lesion on a child's genitalia also should prompt an investigation of sexual abuse. Possible signs of neglect include a dirty or neglected appearance, hunger, extreme sadness or fear, and an inability to communicate. Note any suspicions in the chart and report them to the licensed practitioner before he sees the patient. The practitioner will respond to your information by examining the child for clues to indicate the following:

- Internal injuries: tenderness when palpated or auscultated
- Malnutrition: tooth discoloration, unhealthy gums or skin color
- Lack of cognitive ability: dulled neurologic responses

Studies show that certain risk factors are usually present in parents who abuse their children. Risk factors for child

abuse or neglect include stress, single parenthood, inadequate knowledge of normal developmental expectations, lack of family support, family hostility, financial problems, and mental health problems. Other risk factors include prolonged separation of parent and child, ambivalent feelings toward the child, and a mother younger than 16 years. Additional risk factors include an unhealthy or unsafe home environment, inappropriate supervision, substance abuse, a parental crime record, a negative attitude toward pregnancy, and a history of parents having been abused.

Intervention, such as home visits by healthcare professionals, can significantly lower the rate of child abuse. These professionals provide information on normal child growth and development and routine health needs, serve as informational support persons, and refer families to appropriate services when they require assistance. Keep in mind that according to the law, suspected child abuse and neglect must be reported. If you suspect that a child is being abused or neglected while you are working as a medical assistant, you must inform your supervising licensed practitioner. The practitioner may determine that a child protection agency should be contacted. Keep the child protection agency telephone number posted in your office.

Eating Disorders

Adolescents feel pressured to look good. Whether this pressure comes from modern media—magazines, television, movies, or the Internet—or from an adolescent's peer group, it's often focused on being slim and beautiful, which may include watching the scale and dieting, wearing stylish clothing, and having a certain hairstyle. This pressure may lead adolescents to develop abnormal eating behaviors such as anorexia nervosa. Although not limited to adolescents, patients with anorexia basically starve themselves by not eating. Males and females may suffer from anorexia, but it is more common in females.

Another eating disorder is bulimia nervosa—a pattern of binge eating and purging. Purging is done by vomiting, taking excessive doses of laxatives, abusing diuretics such as Diurex® water pills, or exercising excessively. However, a teen suffering from bulimia may still be of normal weight. Additional information about eating disorders is found in the *Nutrition and Health* chapter.

Depression, Substance Abuse, and Addiction

Signs of depression, addiction, and substance abuse in adolescents can be difficult to distinguish. Signs of substance abuse or addiction can be mistaken for depression. The reverse is also true. Sometimes all three conditions exist simultaneously. The use of alcohol, tobacco, club drugs, marijuana, cocaine, and heroin is an important concern with adolescents. Club drugs include GHB, a central nervous system (CNS) depressant; ecstasy, a mental stimulant that increases physical energy; and flunitrazepam, a sedative-hypnotic similar to Xanax®. The abuse of controlled prescription drugs, such as Ritalin® or Oxycontin®, is equally dangerous. Family members should be aware of and willing to discuss signs of adolescent depression, substance abuse, and addiction with the

CAUTION: HANDLE WITH CARE

Signs of Depression, Substance Abuse, and Addiction in Adolescents

Signs of depression, substance abuse, and addiction are often hard to distinguish in adolescents, partly because adolescents are particularly skilled at hiding the signs of all three disorders. However, various signs may indicate depression in an adolescent. One teenager may lose interest in or be unable to enjoy everyday activities. Another may sleep for long periods and have difficulty getting up in the morning, whereas another may sleep very little. Chronic fatigue or aches and pains may signal depression, as may trouble with concentration or school absenteeism. These signs also may indicate substance abuse or addiction.

It is important to know the difference between substance abuse and addiction. **Substance abuse** refers to the use of a substance, even an over-the-counter drug, in a way that is not medically approved. Inappropriate use includes practices such as using diet pills to stay awake or consuming large quantities of cough syrup that contains codeine. It also includes taking larger-than-prescribed doses of a medication. Substance abusers are not necessarily addicts, however.

Addiction refers to a physical or psychological dependence on a substance. Addiction usually involves a pattern of behavior that includes an obsessive or compulsive preoccupation with a

substance and the security of its supply, as well as a high rate of relapse after withdrawal.

As a medical assistant, you should not try to make a diagnosis. Quite probably, an adolescent with one or more of these disorders will be uncooperative and refuse to answer relevant questions. You must be aware, however, of physical signs and behaviors that may be associated with depression, substance abuse, or addiction in an adolescent patient. The following signs and behaviors are important clues that you should report immediately to the licensed practitioner:

- The patient complains of altered eating habits or disturbed sleep patterns (either too much or too little sleep).
- The patient's weight has changed drastically (either up or down) since the previous office visit.
- The patient appears lethargic or sullen or exhibits radical mood changes.
- The patient has slurred speech.
- The patient appears to have illogical thought patterns.
- The patient appears to have needle tracks (anywhere on the body, especially on the arms or legs).
- The patient has pinpoint (highly constricted) pupils.

licensed practitioner. Although these signs are difficult to evaluate in a short office visit, as the medical assistant, you should also be alert to them. If the practitioner determines that a teen has a substance abuse problem, medical and health counseling services should be provided. Review the *Caution: Handle with Care* feature Signs of Depression, Substance Abuse, and Addiction in Adolescents for more information about this pediatric special concern.

Violence

Violence takes many forms. Teens of many cultures are exposed to violence in movies, television, video games, and music. Excessive exposure leads to insensitivity toward violence. Teens also may be victims of physical, emotional, psychological, or sexual violence at home. Bullying, browbeating, or abusing is recognized as a cause of violence at school. Many youths who have carried out homicidal acts of violence were deeply disturbed by repeated bullying experiences such as being teased, taunted, and rejected by peers. Most students are able to tolerate moderate amounts of teasing, but students who are depressed and harbor resentment and anger for a long time may explode in a violent way. In other cases, the teen may turn inward and commit suicide, which is discussed later. The medical assistant should be aware of the following warning signs of potential violence:

- Frequent physical fighting
- Increased or serious use of drugs or alcohol

- Increase in risk-taking behavior
- Gang membership or strong desire to be in a gang
- Trouble controlling feelings such as anger
- Withdrawal from friends and usual activities
- Feeling rejected or alone
- Having been a victim of bullying
- Feeling constantly disrespected
- Failing to acknowledge the feelings or rights of others

Suicide

According to the Centers for Disease Control and Prevention, suicide is the third leading cause of death for people aged 15 to 24. Unintentional or accidental injury and homicide are the first and second causes, respectively. The suicide rate among young people is greater for males than for females. Females are more likely to attempt suicide than males, but males are more likely to be successful in their first attempt at suicide. Be alert for warning signs:

- Depression
- Anger that is directed inward, toward the self
- Alcohol and/or other substance abuse
- Changes in habit—carelessness, sloppiness, and a lack of interest in personal appearance
- Giving away personal possessions
- Giving verbal hints about committing suicide

If you notice these signs or if you hear someone talking about committing suicide, you should listen and take the person seriously. Never assume that it's "just talk." Discuss your concerns with the licensed practitioner immediately.

Sexually Transmitted Infections and Pregnancy Prevention

Sexually transmitted infections (STIs) threaten long-term health and well-being. They are spread by bloodborne pathogens

and require public education for teens as well as adults. Since teens may engage in sex, they should be aware of STIs and their effects. Teens also should know about pregnancy prevention. Information and education are available through schools, local and state departments of health, television ad campaigns, the Internet, and the Centers for Disease Control and Prevention. Further information about STIs is found in the chapter *The Reproductive Systems*. Additional information about birth control is found in the chapter *Assisting in Reproductive and Urinary Specialties*.

PROCEDURE 40-1 Measuring Infants

WORK // DOC

Procedure Goal: To accurately measure weight and length of infants and infant head circumference

OSHA Guidelines:

Materials: Patient chart/progress note, growth chart, pediatric examining table or infant scale, cardboard, pencil, yardstick, tape measure, disposable towel

Method:

Weight

1. Identify the patient and obtain permission from the parent to weigh the infant.
2. Wash your hands and explain the procedure to the parent.
3. Ask the parent to undress the infant.

RATIONALE: The infant's clothing and diaper can affect the results.

FIGURE Procedure 40-1 Step 3 Mother undressing her infant.

© McGraw-Hill Education

4. Place the disposable towel on the infant scale; then check to see whether it is in balance.

RATIONALE: Balancing the scale ensures accuracy.

5. Have the parent place the child face-up on the scale (or on the examining table if the scale is built into it). Keep one hand over the infant at all times, and hold a diaper over a male patient's penis to catch any urine the infant might void.

RATIONALE: Keeping one hand over the infant can prevent a fall, and holding a diaper over a male patient's penis prevents contamination of yourself and the weighing area with urine.

6. Place the lower weight at the highest number that does not cause the balance indicator to drop to the bottom.

RATIONALE: Doing so ensures accuracy.

FIGURE Procedure 40-1 Step 6 Move the lower weight first.

© McGraw-Hill Education

7. Move the upper weight slowly to the right until the balance bar is centered at the middle mark, adjusting as necessary.

RATIONALE: Doing so ensures accuracy.

FIGURE Procedure 40-1 Step 7 Center the balance bar at the middle mark.

© McGraw-Hill Education

8. Add the two weights together to get the infant's weight.
9. Record the infant's weight in the chart or on the growth chart in pounds and ounces or to the nearest tenth of a kilogram.
10. Return the weights to their starting positions on the left side.

Length: Scale with Length (Height) Bar

11. If the scale has a height bar, move the infant toward the head of the scale or examining table until her head touches the bar.

FIGURE Procedure 40-1 Step 11 Moving the infant toward the head of the scale to measure height.

© McGraw-Hill Education

12. Have the parent hold the infant by the shoulders in this position.
13. Holding the infant's ankles, gently extend the legs and slide the bottom bar to touch the soles of the feet.
RATIONALE: The legs are held to ensure that the correct length will be measured.
14. Note the length and release the infant's ankles.
15. Record the length in the patient's chart or on the growth chart.

Length: Scale or Examining Table Without Length (Height) Bar

16. If neither the scale nor the examining table has a height bar, have the parent position the infant close to the head of the examining table and hold the infant by the shoulders in this position.
17. Place a stiff piece of cardboard against the crown of the infant's head and mark a line on the paper.
18. Holding the infant's ankles, gently extend the legs and draw a line on the paper to mark the heel, or note the measure on the yardstick.

RATIONALE: The legs are held to ensure that the correct length will be measured.

FIGURE Procedure 40-1 Step 18 Holding the infant's ankle to extend the leg and measure for correct length at the heel.

© McGraw-Hill Education

19. Release the infant's ankles and measure the distance between the two markings on the towel or paper using the yardstick or a tape measure.
20. Record the length in the patient's chart or on the growth chart.

Head Circumference

21. With the infant in a sitting or the supine position, place the tape measure around the infant's head at the forehead.

FIGURE Procedure 40-1 Step 21 Wrapping the tape measure around the infant's head at the forehead.

© McGraw-Hill Education

22. Adjust the tape so that it surrounds the infant's head at its largest circumference.
23. Overlap the ends of the tape and read the measure at the point of overlap.
24. Remove the tape and record the circumference in the patient's chart or on the growth chart.
25. Properly dispose of the used towel and wash your hands.

PROCEDURE 40-2 Maintaining Growth Charts

WORK // DOC

Procedure Goal: To accurately document the height, weight, and head circumference of a pediatric patient on a growth chart

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Appropriate growth chart, calculator or BMI calculator, pencil, and pen

Method:

1. Obtain accurate measurements: Weight and stature (height) are measured for children 2 to 20 years who are able to stand. Weight, length, and head circumference are measured for children fewer than 36 months, or 3 years, who are measured while lying down.

2. Select the growth chart to use based on the age and gender of the child being weighed and measured. For boys and girls less than 36 months whom you will be measuring while they are lying down, use length-for-age, weight-for-age, head circumference-for-age, and weight-for-length. When measuring height in a standing position of boys and girls age 2 to 20 years, use weight-for-age, stature-for-age, and BMI-for-age. Charts are available in the workbook that accompanies this textbook or on the website of the Centers for Disease Control and Prevention.

RATIONALE: *The correct growth chart must be used because growth charts are used as a comparison to other patients in the same age category.*

3. Record the patient's name and record number at the top of the form.
4. Record the mother's and father's stature (height) and the gestational age (pregnancy week) at which the infant was born.
5. Record the date of birth, birth weight, length, and head circumference, and add notable comments—for example, breast-feeding. *Note:* This data are not included for growth charts for children age 2 to 20 years.
6. Determine the age based upon the date of birth. For infants, determine the age to the nearest month by subtracting the birth date from the date of the measurement as follows: To subtract, it will be necessary to convert months to days and years to months if either the month or day in the birth data is larger than in the date of measurements. When converting 1 month to days, subtract 1 from the number of months in the date of measurement; then add 28, 30, or 31, as appropriate, to the number of days.

- a. Example A: Patient was born on March 26, 2013, and today is January 13, 2015.

	Year	Month	Day
Date of measurement	2015	1	13
Convert 1 month to days	2015	(−1) 0	(+31) 44
Convert 1 year to months	(−1) 2014	(+12) 12	44
Birthday	2013	3	26
Child's age	1	9	18

Round day to months: 0–15 days = 0 months and 16 to 31 days = 1 month.

When charting for example A patient, you would use 1 year 10 months.

- b. Example B: Child was born on November 27, 2008, and today is May 15, 2015.

	Year	Month	Day
Date of measurement	2015	5	15
Convert 1 month to days	2015	(−1) 4	(+31) 46
Convert 1 year to months	(−1) 2014	(+12) 16	46
Date of birth	2008	11	27
Child's age	6	5	19

Round 5 months and 19 days to 6 months, making the patient 6 years and 6 months. Since the age is over 2 years, round months to nearest $\frac{1}{4}$ year:

0–1 month = 0 year

2–4 months = $\frac{1}{4}$ year

5–7 months = $\frac{1}{2}$ year

8–10 months = $\frac{3}{4}$ year

11–12 months = 1 year

When charting for example B patient, you would use 6 $\frac{1}{2}$ years.

7. Record the date, age, weight, height (stature), and head circumference. Add comments as appropriate, such as “patient uncooperative.”
8. Calculate the body mass index (BMI) if using the BMI-for-age chart. First, convert weight and stature measurements to the correct decimal value using the following table.

Fraction	Ounces	Decimal
$\frac{1}{8}$	2	0.125
$\frac{1}{4}$	4	0.25
$\frac{3}{8}$	6	0.375
$\frac{1}{2}$	8	0.5
$\frac{5}{8}$	10	0.625
$\frac{3}{4}$	12	0.75
$\frac{7}{8}$	14	0.875

Use a calculator and one of the following formulas to determine the BMI:

- $BMI = \text{Weight (kg)} \div \text{Stature (cm)} \div \text{Stature (cm)} \times 10,000$

Example A: Weight = 3.6 kg; Stature = 98 cm

$BMI = 3.6 \div 98 \div 98 \times 10,000$

$BMI = 3.7$

- $BMI = \text{Weight (lb)} \div \text{Stature (in)} \div \text{Stature (in)} \times 703$

Example B: Weight = 36 lb; Stature = 44 $\frac{1}{2}$ in

$BMI = 36 \div 44.5 \div 44.5 \times 703$

$BMI = 12.8$ (rounded from 12.78)

Note: You can also calculate the BMI using an online calculator such as the one found on the National Lung and Blood Institute's website.

9. Plot the measurement on the graph using the data you entered on the chart from the current visit.
 - Find the child's age on the horizontal axis. When plotting weight-for-length, find the length on the horizontal axis. Use a straightedge or right-angle ruler to draw a vertical line up from that point.
 - Find the appropriate measurement (weight, length, stature, head circumference, or BMI) on the vertical

axis. Use a straightedge or right-angle ruler to draw a horizontal line across from that point until it intersects the vertical line.

- Make a small dot where the two lines intersect.

To ensure accuracy, you may want to use a pencil first to mark the small dot, then mark over with pen or a fine tip marker to make the document part of the legal healthcare record.

PROCEDURE 40-3 Collecting a Urine Specimen from a Pediatric Patient

WORK // DOC

Procedure Goal: To collect a urine specimen from an infant or a child who is not toilet-trained

OSHA Guidelines:

Materials: Patient chart/progress note, laboratory request form, urine specimen bottle or container, label, sterile cotton balls, soapy water, sterile water, plastic disposable urine collection bag

Method:

1. Confirm the patient's identity and be sure all forms are correctly completed.
2. Explain the procedure to the child (if age-appropriate) and to the parents or guardians.
3. Wash your hands and put on exam gloves.
4. Have the parent(s) pull the child's pants down and take off the diaper.
5. Position the child with the genitalia exposed.
6. Clean the genitalia. For a male patient, wipe the tip of the penis with a soapy cotton ball and then rinse it with a cotton ball saturated with sterile water. Allow to air-dry. For a female patient, use soapy cotton balls to clean the labia majora from front to back, using one cotton ball for each wipe. Again, use cotton balls saturated in sterile water to rinse the area and allow it to air-dry.

RATIONALE: *The area must be thoroughly cleaned so that microorganisms from the head of the penis or vulva do not contaminate the specimen.*
7. Remove the paper backing from the plastic urine collection bag and apply the sticky, adhesive surface over the penis and scrotum (in a male patient) or vulva (in a female patient). Seal tightly to avoid leaks. Do not include the child's rectum within the collection bag or cover it with the adhesive surface.

8. Diaper the child.
9. Remove the gloves and wash your hands.
10. Check the collection bag every half-hour for urine. You must open the diaper to check; do not just feel the diaper.

RATIONALE: *The diaper should not be wet, and feeling the diaper without looking could dislodge the bag.*
11. If the child has voided, wash your hands and put on exam gloves.
12. Remove the diaper, take off the urine collection bag very carefully so that you do not irritate the child's skin, wash off the adhesive residue, rinse, and pat dry.
13. Diaper the child.
14. Place the specimen in the specimen container and cover it.
15. Label the urine specimen container with the patient's name, ID number, and date of birth; the physician's name; the date and time of collection; and your initials.
16. Remove the gloves and wash your hands.
17. Complete the laboratory request form.
18. Record the collection in the patient's chart (refer to Progress Note).

LEARNING OUTCOMES	KEY POINTS
40.1 Relate growth and development to pediatric patient care.	Growth and development occur in stages throughout life, including neonate, infant, toddler, preschooler, elementary school child, middle school child, and adolescent. Each stage of development occurs through physical, cognitive-intellectual, psycho-emotional, and social milestones.
40.2 Identify the role of the medical assistant during pediatric examinations.	The medical assistant must be able to communicate with pediatric patients of all stages, gather and provide educational information to the parent or caregiver, assist with diagnostic and screening procedures, and serve as a liaison between the patient and the physician.
40.3 Discuss pediatric immunizations and the role of the medical assistant.	Immunizations provide patients with protection from infectious diseases. Throughout life, especially during childhood, immunizations are recommended. The medical assistant may schedule appointments, provide education, obtain informed consent, administer the medication, maintain the immunization record, and properly handle and store the immunizations.
40.4 Explain variations of pediatric screening procedures and diagnostic tests.	Screening procedures and diagnostic tests for pediatric patients vary depending upon the age and size of the child. When performing vital signs, body measurements, vision and hearing tests, specimen collection, or administration of immunizations and medications, follow the specific guidelines for the procedure and child.
40.5 Describe common pediatric diseases and disorders and their treatment.	There are many common childhood diseases including diseases include chickenpox, influenza, measles, mumps, rubella, and tetanus. Other diseases are outlined in Table 40-3.
40.6 Recognize special health concerns of pediatric patients.	The medical assistant should be alert to signs of special health concerns of pediatric patients, including child abuse and neglect; eating disorders; depression, substance abuse, and addiction; violence; suicide; sexually transmitted infections; and unwanted pregnancies.

Now that you have completed this chapter, review the case study at the beginning of the chapter and answer the following questions.

1. Considering Chris Matthews's age, what special aspects of care should you be aware of while caring for him?
2. What information (chief complaint) should you chart regarding Chris?
3. According to his immunization record (see Figure 40-13), what immunizations are missing?
4. What screening and diagnostic tests would you perform or assist the licensed practitioner in performing?

EXAM PREPARATION QUESTIONS

1. (LO 40.1) When Chris was a neonate, he had a high level of bilirubin in his blood. As a medical assistant, you know that he had _____ and needed _____.
 - a. Jaundice; hospitalization
 - b. Jaundice; medication
 - c. Hypobilirubinemia; a bili-blanket
 - d. Jaundice; a bili-blanket
 - e. Hyperbilirubinemia; hospitalization
2. (LO 40.1) Which of the following statements indicates that the parents of a 12-month-old, named Ian, understand the importance of safety for their child?
 - a. "Ian loves to sit on my lap when we drive to the grocery store. It keeps him quiet and happy."
 - b. "Ian got some new toys from his cousin. It says they are for 3-year-olds or older but he plays with them all the time."
 - c. "Ian learned how to turn on the water in the bathtub, so I had my husband set the water temperature on the hot water tank to 140 degrees."
 - d. "We put locks on all the cabinets to keep Ian from opening them."
 - e. "Ian never puts anything in his mouth. He is such a good boy, we let him play with whatever he wants."
3. (LO 40.2) Which of the following would be the most important information to point out to a physician about a pediatric patient?
 - a. A 3-year-old boy is not toilet-trained yet
 - b. An 18-month-old girl just started having temper tantrums
 - c. An adolescent patient does not want his parents to be in the room during his examination
 - d. A 5-year-old girl doesn't want to go to bed at night
 - e. A 7-year-old does not have any friends at school
4. (LO 40.2) If an infant is crying while you are counting respirations, which of the following would be the best course of action?
 - a. Wait until the infant stops crying to continue
 - b. Provide the infant with a pacifier if he uses one
 - c. Have the parent leave the room
 - d. Blow in the infant's face
 - e. Hold the infant more tightly in your arms
5. (LO 40.3) Immunizations are
 - a. Vaccines that protect susceptible individuals from infectious diseases
 - b. Never given to a child who has minor cold symptoms
 - c. Kept at room temperature
 - d. Administered even if contraindications are present
 - e. Recorded in the patient's chart only
6. (LO 40.4) Which method of temperature should *not* be used on a 2-year-old patient?
 - a. Temporal
 - b. Axillary
 - c. Oral
 - d. Rectal
 - e. Tympanic
7. (LO 40.4) Which of the following vital signs would be taken last for an infant?
 - a. Temperature
 - b. Blood pressure
 - c. Pulse
 - d. Respiration
 - e. Pain assessment
8. (LO 40.4) You are to collect a urine specimen on an infant in diapers. Which of the following questions would you *least* likely ask the infant's parent(s)?
 - a. Has your baby experienced enuresis?
 - b. How many diapers are wet each day?
 - c. Does the baby have a persistent diaper rash?
 - d. Does your baby cry when she wets her diaper?
 - e. Has your baby had a fever?
9. (LO 40.5) A parent calls in, stating that her 5-year-old son has a fever of 102 degrees and will not eat. What should you do?
 - a. Suggest that the parent take the child to the emergency room
 - b. Tell the parent to give the child either Tylenol® or Motrin® right away
 - c. Schedule the child for the first available appointment that day
 - d. Tell the parent to give the child a cool bath to lower the child's temperature
 - e. Have the parent call back if the child's fever goes over 102 degrees
10. (LO 40.6) Which of the following is an incorrect or untrue statement regarding child abuse and/or neglect?
 - a. Report only cases of child abuse and/or neglect that you are sure occurred
 - b. Unexplained bruises may be a sign
 - c. Risk factors include young parent, single parent, financial problems, and family stress
 - d. Intervention can lower the rate of child abuse
 - e. Signs of abuse and neglect are not just physical

Go to CONNECT to see a video exercise about Measuring Adults and Children.

A 4-year-old child arrives at the clinic with his mother. She tells you that she recently moved in with her new boyfriend and that her son has been very quiet lately and has not been sleeping well. She also notes that the child has been holding his arm rather strangely since yesterday. What should you do or say?

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Peter Smith	3/28/19XX	NKA
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	428-69-544	Vital signs at this visit: BP 136/88, P 76 and slightly irregular, R 16, T 97.8

Peter Smith, a 73-year-old male with mild Type 2 diabetes, calls to schedule an appointment. He states that he is feeling very anxious and fatigued and is having difficulty eating and sleeping since his wife passed away a few months ago. You notice in his medical record that his sleep issues are ongoing and were present before his wife's death. A sleep study was

© Image Source/Getty Images RF

ordered several months ago, revealing mild nocturnal apnea. At that time, Mr. Smith was given a brochure and was educated on behavior modifications to help prevent apnea. When you ask if these seemed to help, Mr. Smith states that he lost the brochure and does not remember what it said.

Keep Peter Smith in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 41, you will be able to:

- 41.1** Relate developmental changes in geriatric patients to medical assisting practice.
- 41.2** Describe common geriatric diseases and disorders and their treatment.
- 41.3** Identify variations of care for geriatric patients during examinations, screening procedures, diagnostic tests, and treatments.
- 41.4** Explain special health concerns of geriatric patients.

KEY TERMS

- | | |

| geriatrician | patient compliance |
| incontinence | polypharmacy |
| kyphosis | preventive medicine |
| lentigos | prolapse |
| nocturia | sleep apnea |
| osteoarthritis | |

- I.C.6** Compare structure and function of the human body across the life span
- I.C.8** Identify common pathology related to each body system including:
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- I.C.11** Identify the classifications of medications including:
 - (a) indications for use
 - (b) desired effects
 - (d) adverse reactions
- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.9** Assist provider with a patient exam
- I.A.1** Incorporate critical thinking skills when performing patient assessment
- I.A.2** Incorporate critical thinking skills when performing patient care
- V.P.4** Coach patients regarding:
 - (b) health maintenance
- V.P.5** Coach patients appropriately considering:
 - (b) developmental life stage
 - (c) communication barriers
- V.A.3** Demonstrate respect for individual diversity including:
 - (d) age
- X.C.12** Describe compliance with public health statutes
 - (c) wounds of violence
- X.P.3** Document patient care accurately in the medical record

- 2. Anatomy and Physiology**
 - a. List all body systems, their structure and functions
 - b. Describe common diseases, symptoms and etiologies as they apply to each system
 - c. Identify diagnostic and treatment modalities as they relate to each body system
- 3. Medical Terminology**
 - c. Apply various medical terms for each specialty
- 4. Medical Law and Ethics**
 - a. Follow documentation guidelines
- 5. Psychology of Human Relations**
 - a. Respond appropriately to patients with abnormal behavior patterns
 - c. Intervene on behalf of the patient regarding issues/concerns that may arise, i.e. insurance policy information, medical bills, physician/provider orders, etc.
 - d. Discuss developmental stages of life
- 9. Clinical Procedures**
 - c. Assist provider with general/physical examination
 - d. Assist provider with specialty examination including cardiac, respiratory, OB-GYN, neurological, gastroenterology procedures
 - e. Perform specialty procedures including but not limited to minor surgery, cardiac, respiratory, OB-GYN, neurological, gastroenterology
 - h. Teach self-examination, disease management and health promotion
 - j. Make adaptations with patients with special needs

Introduction

Geriatrics is the field of medicine concerned with the conditions related to aging. It is a subspecialty of internal medicine and family medicine. This field is growing because of increases in the average lifespan. Growing numbers of people are living longer, healthier lives. In fact, it is not uncommon now for people to live well into and beyond their 90s. Although there is no specific age at which a patient is prescribed geriatric treatment, in general, **elderly** patients (those over 65) will be cared for by a specialist in geriatrics. These specialists are called **geriatricians**.

According to the US Census Bureau, by the year 2030, more than 20% of the population will be 65 years of age or

older. Given that older people typically have more health concerns, you may find that as a medical assistant, at least 50% of your time will be spent caring for older patients. Keep in mind that the elderly are not simply older versions of young adults. Geriatric patients have unique needs and concerns, which will be discussed in this chapter. Knowledge of the geriatric patient's needs will prepare you to work as a medical assistant in a geriatric practice, as well as in a general medical practice.

The Geriatric Patient

LO 41.1

As individuals age, they experience changes unique to aging. As a medical assistant, you should be aware of the physical changes that make the geriatric patient more prone to certain

diseases and disorders. In addition, geriatric patients experience cognitive-intellectual, psycho-emotional, and social changes. Some aspects of geriatric patient care are age specific.

Physical Changes of Aging

As the body ages, all body systems begin to show signs of aging. It is important to note that not all people experience all changes and that these changes occur at different rates. Let's explore the characteristic signs of aging for the body systems, outlined in the following paragraphs. The systems of the body include the integumentary, nervous, special senses, musculoskeletal, cardiovascular, respiratory, immune, digestive, genitourinary, and endocrine.

Integumentary System Changes in the integumentary system that occur with aging include

- Thinning and wrinkling skin due to decreased amounts of collagen and elastin in the dermis.
- Atrophy, or degeneration, of the subcutaneous layer of skin due to a decrease in adipose tissue.
- Decreased number of cells that produce pigment, or melanocytes, which protect against ultraviolet light. Melanocytes that are still present gather in common locations, causing the brown spots known as **lentigos** or “liver spots” (Figure 41-1).
- Graying, thinning hair.
- Brittle nails.
- Decreasing inflammatory response, resulting in slower healing.

Nervous System Changes in the nervous system that occur with aging include

- Slower reaction time and thought processing.
- Decreased blood flow to the brain due to arteriosclerosis, a group of disorders that cause thickening of the artery walls.

FIGURE 41-1 Fair-skinned individuals are more likely to have lentigos, also called liver spots because they are the color of the liver.

© Dr. P. Marazzi/Science Source

- Shortened attention span and difficulty handling several tasks at one time, caused by decreased frontal lobe size.
- Shrinkage of temporal lobes, leading to weaker signals to the brain for processing.
- Impairment of fine motor activities such as writing, caused by shrinkage of the substantia nigra, a layer of gray matter in the brain.
- Memory loss caused by changes in the part of the brain called the *hippocampus* and a lack of acetylcholine—a chemical that transmits messages between nerve cells or between nerve cells and muscle cells.

Special Senses Changes in the special senses that occur with aging include

- Impaired vision and hearing.
- Altered or decreased taste sensations, which contribute to undereating and possible malnutrition.

Musculoskeletal System Changes in the musculoskeletal system that occur with aging include

- **Osteoporosis**, or decreased bone density, leading to increased incidence of fracture, particularly fractures of the hip.
- **Osteoarthritis** (OA), or degenerative joint disease (DJD) (Figure 41-2).
- Decreased numbers of musculoskeletal fibers.

Cardiovascular System Changes in the cardiovascular system that occur with aging include

- Decreased cardiac output, especially during exercise.
- Arteriosclerosis.
- Postural hypotension, or loss of blood pressure when standing or sitting up abruptly.
- Increased risk of heart disease.

FIGURE 41-2 Also known as degenerative arthritis or degenerative joint disease, osteoarthritis occurs mostly in individuals over the age of 45 years and causes pain, stiffness, and swelling.

© Image Source/Getty Images RF

Respiratory System Changes in the respiratory system that occur with aging include

- Some loss of elasticity of the lungs.
- Calcification of the intercostal cartilage (located between the ribs) and the development of **kyphosis** (curvature of the spine), making it difficult for the lungs to expand properly (Figure 41-3).
- Increased shortness of breath, caused by the physical changes listed above.

Immune System Changes in the immune system that occur with aging include

- Susceptibility to infectious diseases.
- Susceptibility to autoimmune diseases such as cancer and rheumatoid arthritis.

Digestive System Changes in the digestive system that occur with aging include

- Constipation, caused by lack of exercise and poor diet.
- Fecal incontinence, caused by lack of muscle tone.

Genitourinary System Changes in the genitourinary system that occur with aging include

- Decreased number of nephrons, which are the functional units of the kidneys.

- The kidneys filter blood more slowly, causing reduced tolerance to stress, medications, and illness.
- Loss of voluntary control of urination.

Endocrine System Changes in the endocrine system that occur with aging include

- Decreased thyroid function.
- Loss of estrogen production in postmenopausal females.
- Decreasing levels of aldosterone, a hormone that has a role in regulating blood pressure.
- Increase in the time it takes for levels of the hormone cortisol to return to normal after stressful events.
- Deficiencies in response to insulin by various organs.

Cognitive-Intellectual Development

Age-related physical changes in geriatric patients may in turn cause changes in cognitive and intellectual development—how well the patients understand new concepts and learn new skills. Because of changes in the brain, geriatric individuals may take longer to process information. However, they can and do continue to learn. Long-term memory seems to remain intact. Short-term memory may be less acute. If they do not have a disease such as Alzheimer's, they can continue to perform the same functions as they always have. Their accumulated wealth of information and life experiences makes mature adults great teachers.

FIGURE 41-3 Kyphosis, a type of curvature of the spine also known as “humpback,” occurs with age due to degeneration of the spine from a decrease in bone density.

Psycho-Emotional Development

Many changes may occur in the life of the mature adult. In Western cultures, people retire when they are about 65 to 70 years of age. Retirement is a major change that may have benefits or cause difficulties. For example, people who no longer have a career may feel an unexpected sense of loss and grief. Those who have developed interests outside of their careers may make a smoother transition to retirement. Today, however, many older adults keep working because of financial need.

The deaths of a spouse and of friends are more common life events as a person ages. These deaths may have a major effect on a person's emotional and psychological status. Dealing with the deaths of loved ones may also prompt mature adults to face the reality of their own eventual death. Sometimes, physical ailments and the inability to physically and mentally do what they used to do can lead to increasing dependence on other family members—frequently, middle-aged children. This may result in depression in the mature adult who does not want to “be a burden” to the family.

Social Development

Mature adults may experience an increased spirituality. Individuals who are financially and physically able may prefer to remain in their own home and familiar neighborhood. Others choose to move to their “dream” retirement home or community. Most mature adults in the United States live independently, contributing numerous volunteer hours to their communities. Frequently, relationships with grandchildren are a source of great pleasure.

Aspects of Care

Although all patient needs vary, as a medical assistant working with mature adults, you should consider the following points when caring for and providing patient education to geriatric patients:

- Encourage regular weight-bearing and aerobic exercises to reduce and prevent bone loss.
- Provide patient education regarding a balanced nutritional plan. Specifics of a nutritional plan may need to be discussed with a nutritionist or other licensed healthcare practitioner, particularly if there are complicating medical conditions, such as cardiovascular disease or diabetes.
- Question mature adults about their sleeping patterns. As adults reach the age of maturity, their periods of extended sleep may decrease, but short periods of rest during the day may help to offset that loss. Adequate rest helps an individual to be alert and better able to perform the tasks of the day. Disturbances in sleep or excessive fatigue should be reported to a healthcare practitioner.
- Encourage socialization. Social contact persists throughout adult life and should be encouraged. As an adult matures, retires from the world of work, and maybe even loses a spouse, opportunities for socialization may decrease. It is essential that an individual join with other community members to maintain social contact. Frequently, this can be accomplished through volunteer activities.

- Encourage the patient to continue to get regular healthcare checkups, dental care checkups, and breast and prostate exams.
- Remember that the old adage “Use it or lose it!” applies. Keeping the brain active is necessary and can sometimes even prevent loss of function. Studies have shown that individuals who maintain active interests in the world around them maintain mental function better than those individuals who do not.

► Diseases and Disorders of Geriatric Patients

LO 41.2

Aging-associated diseases, or diseases that increase in frequency as individuals age, include cardiovascular disease, hypertension, cancer, arthritis, cataracts, diabetes mellitus, and Alzheimer's disease. Other disorders, such as constipation, diarrhea, and osteoporosis—while not serious for young and middle-aged adults—can be major problems for the elderly. A complete discussion of diseases and disorders that commonly affect mature adults appears in Table 41-1.

► Assisting with Geriatric Care

LO 41.3

Usually, examination, screening, diagnostic procedures, and treatments for geriatric patients are similar to those for younger adults. However, as a medical assistant, you should be aware of variations in the care and treatment of elderly patients. Notice the vast differences in the capabilities of people of this age group, and do not stereotype all elderly patients as frail or confused (most are not). Each patient deserves to be treated according to her own individual abilities. Always treat geriatric patients with respect. Regardless of their physical or mental state, elderly patients are adults. Do not talk down to them. Good communication is necessary. For more information about communication with geriatric patients, see *Points on Practice: Talking with the Geriatric Patient*.

Patient Education

Patient education for elderly patients is especially valuable because it can help them prevent or manage health problems and remain independent. You may need to educate some older patients about the importance of taking measures to protect their health. You may work with elderly patients who have hearing or vision problems or physical limitations that restrict their ability to perform certain tasks. Practice good communication in addition to keeping the following suggestions in mind when educating elderly patients.

- Speak in clear, low-pitched tones. High-pitched voices are more difficult for people with hearing impairments to understand. When asking questions, give the patient time to answer and confirm the response to prevent misunderstandings. Avoid both overly simple “yes” or “no” questions that the patient might answer without thinking and overly complex questions that might confuse the patient.

TABLE 41-1 Diseases of the Elderly

Disease	Description	Treatment
Alzheimer's disease	Severely debilitating brain disorder, with warning signs that include changes in personality, mood, or behavior; recent memory loss and increased forgetfulness; decreased ability to perform familiar tasks; difficulty with use of language and abstract thinking; decreased powers of judgment; and disorientation to time or place	Because there is no cure, the primary role of caregivers is to provide comfort and safety to the patient. Medications such as Aricept® and Namenda® are available that can slow the symptoms of the disease.
Arthritis/osteoarthritis	Chronic inflammatory disease of joint tissues; symptoms include pain, swelling, and stiffness in joints (see Figure 41-2).	Anti-inflammatory medication for inflammation and pain; surgery, including joint replacement in severe cases
Cancer	Abnormal growth of cells that are able to invade other tissues	Surgery, chemotherapy, or radiation therapy; underdiagnosis and treatment as well as side effects of treatment are concerns for geriatric patients
Cardiovascular diseases	Dysrhythmias: abnormal heart rates	Medication or surgery to control the heart rate
	Coronary artery disease: blockages of the arteries surrounding the heart	Stop smoking, improve cholesterol with medication or diet and exercise, angioplasty and/or placement of stents, or coronary artery bypass surgery
	Valvular diseases: abnormalities of the heart valves	Most frequently, surgical repair of the affected valve
	Congestive heart failure	Medication to reduce excessive fluid and edema (diuretics) and to improve the beating of the heart (digoxin, beta blockers)
Cataracts	Lens of the eye becomes cloudy and opaque, causing decreased vision.	Sunglasses, improved lighting, and changing of glasses; cataract surgery to replace the lens
Constipation-diarrhea cycle	The cycle of constipation followed by diarrhea occurs when people's diets lack the fiber and liquids to maintain healthy bowel function and they use harsh laxatives to treat their constipation. The patient then complains of diarrhea and asks for antidiarrheal medication, which in turn causes constipation again.	Encourage elderly patients to eat more high-fiber foods, such as cereals, fruits, and vegetables, and to increase their fluid intake, as well as increase their activity level if possible.
Diabetes mellitus Type 2	High levels of sugar (glucose) in the blood; symptoms include fatigue, hunger, increased thirst, increased urination, and even blurred vision	Diet, exercise, and weight control; monitoring of blood sugar; oral medications such as metformin and, in rare cases, insulin
Hypertension	Elevation of blood pressure over 140 systolic and 90 diastolic; often, there are no symptoms or symptoms are mild	Medications to reduce blood pressure; dietary restrictions to reduce fat and sodium and lose weight; increased exercise to lose weight and strengthen the heart
Hyperlipidemia	A condition in which lipid (fat) levels are above normal. These include cholesterol and triglycerides. Although not just a disease of the elderly, it tends to be more common and serious with age. High cholesterol levels can lead to atherosclerosis, the accumulation of fatty deposits along the inner walls of arteries (Figure 41-4). These deposits, along with other substances in the blood, can form an atherosclerotic plaque. This plaque can narrow the opening in an artery to the point of obstructing blood flow. Atherosclerosis is a primary cause of cardiovascular disease and stroke.	Teach patients about eating foods with lower amounts of cholesterol and increasing exercise. Provide patients with printed materials about hyperlipidemia and cholesterol. The doctor may prescribe medication (statins) to lower cholesterol in patients when diet modification and exercise are not effective.
Osteomalacia	Softening of the bones due to vitamin D and calcium deficiency, especially in postmenopausal women	Teach patients about the need for proper nutrition; encourage postmenopausal women to take vitamin and mineral supplements as needed.
Osteoporosis	An endocrine and metabolic disorder of the musculoskeletal system. Thinning of bone tissue and loss of bone density occur over time, leading to fractures. More common in women than men, this disorder may be caused by inadequate calcium consumption, estrogen deficiency, or alcoholism.	Prevention methods include regular weight-bearing and strength exercises and a diet high in calcium (perhaps including supplemental calcium). Prescription medications, such as Fosamax® or Actonel®, and hormone replacement therapy also are used.

(Continued)

TABLE 41-1 Diseases of the Elderly

Disease	Description	Treatment
Sleep apnea	Sleep disorder in which the person stops breathing for several seconds at a time while sleeping; if not treated, can predispose the patient to other, more serious complications such as cardiovascular disease, depression, and even memory loss.	In mild cases, teach patients behavioral changes such as losing weight, avoiding alcohol, stopping smoking, avoiding sleeping pills, and avoiding sleeping on the back. In more severe cases, the licensed practitioner may recommend a continuous positive airway pressure (CPAP) machine, which provides the patient with a continuous flow of air into the nose to keep the airway open. Some practitioners also recommend dental devices to help keep the airway open. In very severe cases, surgery may be needed. See the <i>Educating the Patient</i> feature Sleep Disorders for more information about behavioral modification.

POINTS ON PRACTICE

Talking with the Geriatric Patient

Communication is key to successful practice as a medical assistant. The following tips will help you and the patient communicate with each other more effectively.

- Make sure you select a private setting for the patient interview.
- Many older patients are hard of hearing but not deaf. Speak slightly more slowly than you normally would. Speak clearly and loudly (but do not shout—shouting will insult and anger an older patient who does hear well). Enunciate well and use a lower tone of voice (elderly people lose the ability to hear high-frequency sounds first). If the patient asks you to repeat a question, rephrase it instead of repeating it verbatim.
- Look at the patient directly so that she knows you care about what she has to say and so that you can make sure she understands what you tell or ask her.
- You can show respect for the patient's age by addressing the patient with *Mr.*, *Mrs.*, *Ms.*, or *Miss*, unless the patient asks to be called by his or her first name.
- Be patient. Some older patients live alone or in relative isolation and may be out of practice with the two-way communication skills that make a conversation or interview go smoothly. The simple act of being interviewed, even for what may seem to you a straightforward medical history, may unsettle the older patient. For example, he may need to stop and think of a word here and there. Do not supply the word. Wait and let the patient think of it on his own. Also, do not rush through your questions. Rushing will only make the patient feel anxious and incompetent if he feels he cannot keep up with you.
- Practice active listening skills. Pay attention to the patient's verbal and nonverbal cues. Do not interrupt the patient.

After the patient finishes giving each answer, repeat it to give her a chance to correct you if you misheard or misunderstood.

- If you are interviewing the patient to obtain a medical history, before you begin, explain the type of questions you will ask and how the information will be used.
- If you need to use medical terminology, try also to express the same information in lay terms. For example, you might ask, "Do you use a diuretic, or pill to help you eliminate fluids?"
- Be cheerful and friendly but not sugary-sweet. Do not talk down to older patients; they are not stupid.
- Avoid sounding surprised or excited by any answer to a question or to any information the patient gives.
- Under no circumstances use endearments such as *dear*, *honey*, or *sweetie*.
- Look for ways to make a connection so that the patient feels relaxed and comfortable. For example, in the course of taking a patient's history, you might find out that he enjoys swimming. Ask him to tell you about it.
- Show an interest in the patient as a person. Ask about something she is interested in. For example, a patient might be wearing a piece of handmade jewelry. Ask where it came from. She might have a wonderful story to tell.

Obtaining Information from a Geriatric Patient.

EDUCATING THE PATIENT

Sleep Disorders

Although some researchers believe that sleep requirements decline with age, according to the National Sleep Foundation, a person's need for sleep remains more or less constant throughout life. Seniors tend to have a harder time getting to sleep, and the quality of their sleep is not as high as that of younger people.

Many sleep disorders can affect the sleep of geriatric patients, including sleep apnea, insomnia, restless leg syndrome, and lack of sleep due to symptoms of ongoing diseases such as chronic obstructive pulmonary disease (COPD), gastroesophageal reflux disease (GERD), or even pain associated with arthritis.

Medications may be prescribed for some sleep disorders, but most licensed practitioners prefer to try behavioral and lifestyle changes, referred to as “sleep hygiene,” before prescribing medications.

Commonly recommended actions include:

- Go to bed at the same time every evening.
- Wake up at the same time every morning.
- Try not to take long naps during the day.
- Get regular exercise, but avoid exercising just before going to bed.
- Avoid consuming alcohol, caffeine, and nicotine before bedtime.
- Form routine habits for getting ready for bed, such as washing or brushing your teeth.
- Maintain a sleep environment that is conducive to sleep, such as a darkened, quiet room.
- Do not perform activities such as reading or watching television in bed.
- Do not eat heavy meals close to bedtime.

FIGURE 41-4 High cholesterol can lead to atherosclerosis. Help patients reduce their cholesterol through proper diet and exercise, along with medication, if prescribed.

limitations they have and adjust the procedure accordingly. Make sure patients understand the instructions by asking them to perform the procedure for you.

Denial or Confusion

Sometimes elderly patients, just like many other adult patients, deny that they are ill. A patient's perception of how he feels may be quite different from his actual state of health. The reverse situation also can occur. Elderly patients may overreact to a problem and consider themselves sicker than they really are. They may become dependent, passive, or anxious.

Elderly patients also may over- or underestimate their ability to perform certain tasks or to deal with certain limitations. Elderly patients may be confused if they have some impairment in memory, judgment, or other mental abilities. Signs of confusion can occur with Alzheimer's disease and other types of dementia, depression, head injury, or misuse of medications or alcohol. Elderly patients may or may not be aware of their condition. They may have difficulty understanding instructions.

The Importance of Touch

Therapeutic touch is based on an ancient therapy called the laying on of hands. It was reconceived in the early 1970s by a registered nurse. Essentially, the hands are used to direct human energies to help or heal someone who is ill. Although little scientific evidence exists about the effectiveness of this therapy, it is known that touch can improve health and well-being.

Because they often live alone, many elderly patients experience a lack of physical touch. Using touch—offering to hold a patient's hand or placing an arm around his

- Some older people have trouble understanding directions. Try to communicate with them at the highest level they can understand. Remember, never talk down to patients.
- Put instructions in writing. Because some elderly patients have problems with memory, detailed written instructions are an essential aspect of patient care. Patients can refer to the instructions as necessary or ask a relative to do so.
- Adjust procedures as needed. When demonstrating a procedure to elderly patients, keep in mind any physical

shoulder—communicates that you care about the patient, and it may improve his health and well-being (Figure 41-5).

Incontinence

Elderly patients may suffer from urinary **incontinence**, or involuntary leakage of urine. Many people are too embarrassed to ask for help or are unaware of possible solutions. In general, if a patient has urinary incontinence that interferes with day-to-day life, the licensed practitioner should be notified of the problem. Incontinence will sometimes cause a patient to drink less, making her prone to urinary tract infections and other problems.

Preventive Medicine

Many elderly patients may not be aware of or do not practice the concept of **preventive medicine** (measures taken to prevent illness). They are from environments in which people went to a doctor only when they were very ill. So they do not realize the importance of preventive measures such as regular checkups, digital rectal exams, immunizations, and colonoscopy. Also, older women often do not recognize the need for regular mammograms and Pap smears to detect cancers of the breast and cervix.

As a medical assistant, you should use any educational tools available to you to make elderly patients more aware of the importance of preventive measures. If you reinforce the doctor's recommendations with education, you increase the chance that patients will heed the advice they are given.

Lack of Compliance When Taking Medications

Often, geriatric patients need several medications, and many of them find it difficult to keep track and take the right medication at the right time. Sometimes patients have difficulty swallowing or simply decide not to take a medication because they feel they do not need it. In your role as a medical assistant, you can help by telling geriatric patients about available medication reminder boxes, timers,

and medication organizers. These devices can help ensure **patient compliance** (obedience in following the orders of the licensed practitioner). Patient compliance helps patients remain healthier and get well faster.

Collecting Urine Specimens

Consider the following when you are collecting urine from a geriatric patient: Bladder muscles weaken with age, often leading to incomplete bladder emptying and chronic urine retention, which can cause urinary tract infection, **nocturia** (excessive nighttime urination), and incontinence.

Weakening of the supports of the uterus may cause it to **prolapse** (work its way down the vaginal canal). The uterus pulls with it the vaginal walls, bladder, and rectum. This weakening—often the result of several childbirths—may not occur until a woman is postmenopausal. Symptoms include pressure, incontinence, and urinary retention. Normal activities, such as walking up stairs, can aggravate the problem.

Find out whether the patient ever loses bladder control. If so, ask whether it occurs suddenly or whether a feeling of intense pressure precedes it. These symptoms can be a sign of weakening of the bladder muscles.

Keep in mind that some elderly patients need assistance in providing a urine specimen. For example, you may have to accompany the patient to the bathroom and hold the specimen container. (Wash your hands before and after doing so, and wear gloves while providing this help.)

Conditions of the urinary system, especially the bladder, in the elderly can interfere with collecting urine specimens. This is especially true for 24-hour urine specimens. Careful and repeated explanations or reminders about the procedure or the specimens needed may be necessary to ensure accuracy.

Blood-Drawing Procedures

The challenges presented by elderly patients may test your technical skills as well as your interpersonal skills. Physically, some older adults are frail and may not withstand blood-drawing procedures as easily as younger patients. Changes in skin condition often make elderly patients more prone to bruising and other injuries. Decreased circulation may make it difficult to collect enough blood for an adequate sampling. Be aware of these issues and take extra precautions when drawing blood on an elderly patient.

Hot and Cold Therapy

Elderly patients are usually more sensitive than others to cold and heat. As you may have noticed with elderly friends and relatives, there is a reduced ability to tolerate temperature changes. Sudoriferous (sweat-producing) glands of the skin decrease in number and, with less perspiration, high temperatures are more difficult to adjust to. At the same time, the loss of adipose tissue and decreased circulation result in a lessened ability to retain heat, which increases sensitivity to cold.

Along with possible poor circulation, geriatric patients also may have arthritis; impaired sensation; kidney, heart, or lung disease; or atherosclerosis. They also may have

FIGURE 41-5 The importance of touch: Elderly patients may appreciate your touch as a sign of caring. Consider offering to hold their hand or placing an arm around their shoulder.

© Royalty-Free/Corbis

impaired skin integrity—thinning of the skin, resulting in increased risk of skin tearing, bruising, and burning. When administering cryotherapy (cold therapy) or thermotherapy (heat therapy), stay with an elderly patient during its application to check the patient's skin frequently for excessive paleness or redness.

Nutritional Guidelines

Universal nutritional guidelines for aging patients have not been developed. It is known, however, that energy and metabolic requirements usually decline with age, which calls for some dietary modification. The Food and Nutrition Board of the National Academy of Sciences recommends a 10% decrease in caloric intake for people over age 50 compared with that of young adults. Men and women older than age 75 should decrease their intake another 10% to 15%. The exact adjustment, however, depends on the individual patient's condition and needs.

Because protein requirements do not change, elderly patients should select foods that provide ample protein in a smaller quantity of food. To achieve daily nutritional goals, patients may require supplements for iron, calcium, and other minerals, such as phosphorus and magnesium.

Aging is often accompanied by decreased gastrointestinal muscle tone, so elderly patients should increase their intake of high-fiber foods and drink plenty of water. Of course, all people need to have an adequate amount of daily water. However, elderly patients sometimes restrict their fluid intake because they may need to urinate frequently, do not remember, or do not understand the importance of keeping the body well hydrated by consuming enough fluid. See Procedure 41-1 at the end of this chapter. Poor fluid intake also can quickly lead to urinary tract infections in mature adults.

Although all people need a certain amount of fat in their diet to help the body absorb vitamins, too much may lead to atherosclerosis. Elderly individuals should keep fat intake to 20% of their total calories.

Certain factors can impair or impede eating in this age group and may even lead to malnutrition. If you recognize any of these factors, discuss them with the patient's doctor:

- Physical factors, such as chewing difficulty caused by tooth loss or poorly fitting dentures, swallowing difficulty, and lack of appetite caused by altered taste, smell, or sight
- Medications, which may adversely affect food intake or nutrient use
- Social factors, including apathy toward food caused by depression, grief, or loneliness
- Economic factors, including homelessness or lack of money for food or transportation

Many types of adaptations can be used to help ensure that the nutritional needs of mature adults are met. To overcome physical factors, seeing to the patient's dental needs can help. Assistive devices such as plates with high edges that help keep food from falling onto the table can help the patient scoop

food onto serving utensils. Using nonskid placemats may help keep the dishes from sliding around.

To counteract social factors such as loneliness and depression, it may help to suggest eating frequently with friends or neighbors. Patients who live alone may also benefit from using tablecloths, cloth napkins, and attractive centerpieces to make dining a more pleasant experience. Other health-care team members, such as social workers, may need to be consulted if economic factors are interfering with a patient's nutritional status.

Immunizations

Influenza and influenza-related pneumonia represent a serious health risk for patients older than age 65. Although elderly patients can be immunized against influenza each year and against influenza-related pneumonia one time, they may have misconceptions about vaccinations. Another recommended vaccine for individuals over 60 is the shingles vaccine. No matter the vaccine, geriatric patients may worry about the expense, the possibility of getting the disease from the vaccine, or the need for a vaccination when they do not feel ill.

Explain to patients who are concerned about the cost of vaccinations that if they are not enrolled in one of the many insurance plans that cover immunization, Medicare Part B covers the cost. For those worried about the potential side effects of immunization, describe the mild symptoms they may encounter and emphasize that the symptoms are short-lived. You also might mention that compared to the potential dangers of contracting a serious infection, the symptoms are quite mild.

Because older patients are much more likely than younger patients to develop side effects as a result of immunizations, instruct older patients so that they recognize and immediately report any adverse reactions. That way, the licensed practitioner can treat elderly patients before their illness becomes severe.

► Geriatric Patient Special Concerns **LO 41.4**

As you can see, geriatric patients require a lot of special consideration. Four additional special concerns when working with the elderly are falls, depression, elder abuse, and polypharmacy.

Preventing Falls in the Elderly

Falls can occur at any age, but in the elderly, they can have especially serious consequences. Bones may become brittle with age due to osteoporosis, and falls can cause breaks in major bones, such as those in the hip and wrist. Complications from falls and bone fractures can lead to death in individuals in this age group.

The elderly are prone to falling because of vision problems, slowing reflexes, quick position changes that can lower the blood pressure, and changes in the ear that cause equilibrium problems. In addition, medications can increase the risk of falls because they may make the patient less alert or cause dizziness.

As a medical assistant, you should discuss a safety checklist with elderly patients and their families. Point out that by taking precautions, elderly patients can reduce the risk of falling. Make sure patients and their families understand the following instructions:

- Remove reading glasses before getting up and walking around.
- Make sure that potentially hazardous areas, such as stairs and doorway entrances, are well lit.
- Use night-lights in the bedroom and bathroom to help prevent night falls.
- When getting up from a reclining or recumbent position, sit at the edge of the bed for a few minutes before trying to stand to allow blood flow and blood pressure to adjust.
- Wear well-fitting shoes with low heels and slippers with nonslip soles.
- Use a cane or walker if you are unsteady on your feet.
- Secure rugs and floor coverings to the floor to prevent slippage.
- Attach all electrical cords to the walls or floor moldings.
- Place sturdy banisters along all stairs inside and outside the home.
- Install secure handrails near the bathtub and toilet.
- Apply nonslip appliques to the bathtub and shower floor.
- Minimize clutter in the home.
- Store frequently used items within easy reach.

Depression

Depression is common in the elderly, but many of the symptoms of depression mimic those of other conditions. As a medical assistant, you can help elderly patients—and their families—recognize the signs of depression. Recall Mr. Peter Smith from our case study at the beginning of the chapter. What symptoms does he have? Do you think he has depression? Knowing what to look for may help patients seek help sooner than they otherwise would and receive prompt diagnosis and treatment. See the *Caution: Handle with Care* feature Helping Elderly Patients with Depression for a discussion of the symptoms and treatment of depression in the elderly.

Elder Abuse

Even though you may need to communicate verbally with an elderly patient's caregiver, always observe the elderly patient for nonverbal signs of problems such as grimacing, foul odors, or bruising even if the patient cannot speak to you verbally. Disabilities may make the elderly person defenseless against abuse, and a medical assistant should be alert to signs of abuse.

It is difficult to detect elder abuse. There is no uniform and comprehensive definition of this type of abuse, and bruises from falls and other accidents can be mistaken for abuse. Also, the signs of neglect can be similar to the signs of some chronic medical conditions. There are three basic categories of elder

abuse: domestic elder abuse, institutional elder abuse, and self-neglect, or self-abuse. Elders can be abused physically, sexually, or psychologically. Elders may also be neglected, abandoned, or exploited materially or financially. Elders may even choose to neglect or abuse themselves. More than one type of abuse can occur simultaneously. Elder abuse occurs in all racial, socioeconomic, and religious groups. However, most victims are older women with chronic illness or disabilities. Risk factors and situations that increase the possibility of elder abuse include

- History of alcoholism, drug abuse, or violence in the family.
- History of mental illness in the abuser or victim.
- Isolation of the victim from family members and friends other than the abuser.
- Recent stressful events affecting the abuser or victim.

Signs of neglect include

- Foul odor from the patient's body.
- Poor skin color.
- Inappropriate clothing for the season.
- Soiled clothing.
- Extreme concern about money.

You can assist the doctor by taking a careful history. Ask the patient about living arrangements, social contact, and emotional stress. Note the interaction between the caregiver and the patient. Be aware that a patient with dementia may be abused but is not able to report it and the caregiver may be able to cover it well. If you suspect abuse, inform the doctor. He will then be able to direct the physical exam toward possible internal injuries, malnutrition, or lack of cognitive ability. Most states require doctors who suspect elder abuse or neglect to report their concerns to a designated office. Early intervention usually results in better living arrangements for both the patient and the caregiver.

Polypharmacy

Age-related changes in the body can affect drug absorption, metabolism, distribution, and excretion. These normal changes can be exaggerated by various diseases or disorders. So as people age, they have an increased risk of drug toxicity, adverse reactions, or lack of therapeutic effects. Because of this risk, be especially alert when assessing an elderly patient who is on drug therapy.

Many elderly patients have complex, chronic diseases with unusual symptoms. This situation can make it difficult to tell whether a problem is caused by a drug. Listen closely to elderly patients and their family members; they are more likely to notice subtle changes than you are.

Patient and family education are important with elderly patients, particularly if they engage in **polypharmacy** (take several medications concurrently). Polypharmacy is common in elderly patients, and drug-drug interactions can be severe. See the *Caution: Handle with Care* feature Preventing Unsafe Polypharmacy.

CAUTION: HANDLE WITH CARE

Helping Elderly Patients with Depression

The National Institutes of Health (NIH) considers depression in people age 65 and older to be a major public health concern. In fact, suicide is more common among the elderly than any other age group. The NIH also indicates that only about 10% of elderly people who need treatment for depression ever receive it.

One reason for the low rate of treatment is that many older people—and their families—believe that depression is a normal consequence of growing old. After all, older people may experience many difficult life changes, including enduring the deaths of a spouse and siblings, adjusting to retirement, being alone, dealing with a relocation, suffering economic hardship, and managing a variety of physical ailments. Because of these circumstances, doctors and family may miss the signs of depression.

Recognizing the Symptoms

There is, unfortunately, no specific diagnostic test for depression, so a diagnosis must be made on the basis of symptoms. The symptoms of depression in the elderly are similar to those in other age groups and include the following:

- Decreased ability to enjoy life or to show an interest in activities or people
- Slow thinking, indecisiveness, or difficulty in concentrating
- Increased or decreased appetite
- Increased or decreased time spent sleeping
- Recurrent feelings of worthlessness
- Loss of energy and motivation
- Exaggerated feelings of sadness, hopelessness, or anxiety
- Recurrent thoughts of death or suicide

The failure to realize that symptoms like these indicate an illness prevents many older people from seeking help. However, there is evidence that treatment for depression in the elderly can be highly effective.

Treatment for Depression

Depression has been linked to poor diet, lack of exercise, and reduced social contacts. Modification to these things may improve symptoms of mild depression. However, treatment for clinical depression generally combines a course of antidepressant drugs with psychotherapy. Older patients generally respond to antidepressants more slowly than younger patients,

so older patients may not experience relief until more than 6 weeks after starting treatment. For this and other reasons, compliance in taking medications for depression is a problem with the elderly. Many elderly patients do not understand depression and the importance of taking medications as prescribed. They also may be frightened by the idea of taking medication for a mental problem. Psychotherapy aims to help older patients talk through their anxieties, develop coping skills, and improve the quality of their lives. Again, compliance is a problem. Many older adults are unwilling to admit that they have a mental health problem and refuse to follow up on referrals to mental health professionals.

Benefits of Treatment

Elderly patients who follow a course of treatment for depression benefit in several of ways. They gain

- Relief from many of the symptoms associated with depression.
- Relief from some of the pain and suffering associated with physical ailments.
- Improved physical, mental, and social well-being.

Healthcare providers, including you as the medical assistant, can play a significant role in recognizing symptoms of depression in elderly patients and in encouraging them to get the treatment they need.

© Design Pics/Kristy-Anne Glubish RF

If an elderly patient is forgetful or confused, talk to the licensed practitioner about simplifying the medication schedule to reduce the risk of drug administration errors or omissions. If the patient has vision problems, provide drug instruction sheets in large type. To do this, type instructions

on a word processor in a large type size, enlarge the instructions on a photocopier, or clearly handwrite the instructions in large block letters. You also might contact a local association for the blind or visually impaired for devices and tips.

CAUTION: HANDLE WITH CARE

Preventing Unsafe Polypharmacy

Before administering any drug by any route, you must know every drug, both prescription and nonprescription, that the patient is taking. Many patients, especially elderly ones, visit several doctors. It is possible that each doctor prescribes one or more drugs without being aware of other drugs the patient is taking. This practice can result in polypharmacy, which means taking several drugs at once. Polypharmacy can be safe, but if the doctor is unaware of the total drug profile, serious drug interactions can result.

When asking patients to identify *all* other drugs they are taking, including OTC drugs, keep in mind that patients may forget to mention all their medicines, OTC drugs, supplements, or herbal remedies to the doctor. Patients often forget to mention antacids (such as Tums® or Rolaids®), supplements that are part of a food or drink (such as flavored drinks with glucosamine-chondroitin), medicines that are used only as needed such as medicine for migraine headaches, vitamins, and herbal remedies such as ginkgo biloba or omega-3.

To help prompt patients about drugs they may have forgotten, ask patients who have seen an orthopedist or a cardiologist whether pain medication has been prescribed. Ask women who have seen a gynecologist if they are using a patch or other form of hormone replacement therapy. Ask all patients if they take any other dietary supplement, OTC medication, and/or herbal

remedy. If a patient has been referred to any other doctor for any reason, ask whether that doctor has prescribed medication. After determining the total drug profile, you should

- Update the patient's record (this should be done with every visit to your facility).
- Consider possible drug interactions, consulting online drug interaction checkers or other drug references, such as the *PDR*, if needed.
- Inform the licensed practitioner of your findings.

PROCEDURE 41-1 Educating Adult Patients About Daily Water Requirements

WORK // DOC

Procedure Goal: To teach patients how much water their bodies need to maintain health

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Patient education literature, patient's chart/progress note, and device to document education

Method:

1. Explain the importance of water to the body. Point out the water content of the body and the many functions of water in the body, including maintaining the body's fluid balance, lubricating the body's moving parts, and transporting nutrients and secretions.
2. Add any comments applicable to an individual patient's health status, such as issues related to medication use, physical activity, fluid limitation, or increased fluid needs. For example, geriatric patients have decreased gastrointestinal motility and require water to avoid constipation.

RATIONALE: Some elderly patients purposely limit their fluid intake because of incontinence or physical limitations that make getting to a bathroom difficult, so it is necessary to provide specific comments about their exact fluid needs.

3. Explain that people obtain water by drinking water and other fluids and by eating foods that contain water. On average, an adult should drink six to eight glasses of water a day to maintain a healthy water balance in which intake equals excretion. People's daily need for water varies with size and age, the temperatures to which they are exposed, the degree of physical exertion, and the water content of foods eaten. Make sure you reinforce the physician's or dietitian's recommendations for a particular patient's water needs.
4. Caution patients that soft drinks, coffee, and tea are not good substitutes for water and that it would be wise to filter out any harmful chemicals contained in the local tap water or to drink bottled water, if possible. A good rule

FIGURE Procedure 41-1 Step 5 Using a water bottle can help patients remember to drink a certain amount of water each day.
© Steven Puetzer/Getty Images RF

of thumb is that for every soft drink, coffee, or tea, the patient should drink the same amount of water to ensure hydration.

5. Provide patients with tips about reminders to drink the requisite amount of water. Some patients may benefit from using a water bottle of a particular size, so that they know they have to drink, say, three full bottles of

water each day. Another helpful tip is to make a habit of drinking a glass of water at certain points in the daily routine, such as first thing in the morning and after lunch or right before bedtime if it does not interrupt your sleep.

6. Provide patients with printed materials documenting the amount of water to drink and methods to ensure that their fluid intake is adequate.
7. Remind patients that you and the licensed practitioner are available to discuss any problems or questions.
8. Document any formal patient education sessions or significant exchanges with a patient in the patient's chart or on a progress note, noting whether the patient understood the information presented (refer to Progress Note).

RATIONALE: Many insurance companies require evidence of preventive health counseling, and documentation is an important aspect of patient insurance coverage.

PROGRESS NOTE

Patient Name:

Dolores Black

Water needs explained to patient, including the body's use of water, the need to increase water, and tips for increasing water in diet. Patient stated she understood the need to increase water and would implement a plan to increase her intake of water. No questions asked.

SUMMARY OF LEARNING OUTCOMES	
LEARNING OUTCOMES	KEY POINTS
41.1 Relate developmental changes in geriatric patients to medical assisting practice.	Geriatrics is a subspecialty of internal medicine or family practice. Geriatricians typically care for patients over the age of 65. These patients have multiple physical changes as well as variations in psycho-emotional, cognitive-intellectual, and social development to consider when working as a medical assistant.
41.2 Describe common geriatric diseases and disorders and their treatment.	Common aging-associated diseases and disorders include cardiovascular disease, hypertension, cancer, arthritis, cataracts, diabetes mellitus, Alzheimer's disease, constipation, diarrhea, osteoporosis, osteomalacia, and sleep apnea. Understanding these will help you prepare to care for geriatric patients.

LEARNING OUTCOMES	KEY POINTS
41.3 Identify variations of care for geriatric patients during examinations, screening procedures, diagnostic tests, and treatments.	When working with geriatric patients, you must treat them with respect and dignity. Be aware of their physical and mental changes so that you can adapt your care to meet their needs.
41.4 Explain special health concerns of geriatric patients.	Each of the following special concerns should be handled appropriately when caring for the elderly: falls, elder abuse, depression, and polypharmacy.

CASE STUDY CRITICAL THINKING

© Image Source/Getty Images RF

Recall Peter Smith from the beginning of the chapter. Now that you have completed this chapter, answer the following questions regarding his case.

1. Considering Mr. Smith's age, what special aspects of care should you be aware of while caring for him?

2. Why would Mr. Smith be prone to falls, and what can you do to help prevent them?

3. You need to collect a urine specimen from Mr. Smith. What special considerations should you take?

4. What symptoms does Mr. Smith have, and why is it important for you to recognize them?

EXAM PREPARATION QUESTIONS

- (LO 41.1) Which of the following is the *least* likely to occur with a geriatric patient?
 - Incontinence
 - Kyphosis
 - Hyperbilirubinemia
 - Polypharmacy
 - Lentigos
- (LO 41.1) Your 68-year-old patient suffers from pain and swelling of his left knee. He also has poor vision and hearing. He needs education about how to care for his knee. Which of the following would be the best technique?
 - Looking at your patient education sheet, give him simple directions at his level
 - Perform patient education in an open area of the clinic to prevent him from being uncomfortable
 - Have him go to a small class to teach him about his care
 - Speak in clear, high-pitched tones so that he can hear you
 - Look directly at the patient, speaking slightly slower in low-pitched tones
- (LO 41.2) Which of the following patients is *most* likely to suffer from urinary incontinence?
 - A 78-year-old female patient with a prolapsed uterus
 - A 65-year-old male patient with nocturia due to an enlarged prostate
 - A 76-year-old female patient taking 12 different prescription medications and 2 over-the-counter supplements
 - A 68-year-old male patient with a history of alcoholism
 - An 82-year-old patient who uses a walker for ambulation
- (LO 41.2) Your 68-year-old patient suffers from disorientation to time and place. Which of the following is the *most* likely problem?
 - Cataracts
 - Valvular disease
 - Depression
 - Alzheimer's disease
 - Osteoporosis

5. (LO 41.3) When speaking to Peter Smith, which of the following is the best way to address him?
 - a. Hi, Pete, how are you doing today?
 - b. Mr. Smith, how are you feeling today?
 - c. Sir, I would like to take your vital signs.
 - d. What is your chief complaint today, mister?
 - e. Hi there, honey, will you sit down right here so we can start the interview?
6. (LO 41.3) Your elderly patient refuses an immunization. Which of the following is the *least* likely reason?
 - a. He is worried about the expense
 - b. He had a severe reaction to a previous immunization
 - c. He does not feel bad and does not want to feel bad
 - d. He does not have time to wait for the injection
 - e. He is afraid he will get the disease from the vaccine
7. (LO 41.3) When providing nutritional education for an elderly patient, which of the following statements is *most* accurate?
 - a. You will need to decrease the amount of protein in your diet
 - b. As you age, you will require more calories in your diet
 - c. High-fiber food and plenty of water should be included in your diet
 - d. Your daily intake of fat should be at least 30% or more
 - e. The medications you take will not affect your dietary intake
8. (LO 41.2) Which medication would *most* likely be given to an elderly patient with congestive heart failure?
 - a. Statin
 - b. Glucophage®
 - c. Actonel®
 - d. Aricept®
 - e. Digoxin
9. (LO 41.4) Which of following is *not* a practice of preventive medicine?
 - a. Biopsy
 - b. Colonoscopy
 - c. Mammogram
 - d. Immunization
 - e. Pap smear
10. (LO 41.4) Which of the following patients is engaging in polypharmacy?
 - a. A 78-year-old female patient with a prolapsed uterus
 - b. A 65-year-old male patient with nocturia due to an enlarged prostate
 - c. A 76-year-old female patient taking 12 different prescription medications and 2 over-the-counter supplements
 - d. A 68-year-old male patient with a history of alcoholism
 - e. An 82-year-old patient who uses a walker for ambulation

SOFT SKILLS SUCCESS

You are assisting with an examination of an 80-year-old female patient who is at the clinic with her daughter. When the daughter steps out of the room to speak to the licensed practitioner, the patient states, “You know, she pinches me all the time.” You note that she has some bruises on her left forearm. What should you do or say?

Assisting in Other Medical Specialties

42

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Valarie Ramirez	8/4/19XX	PCN
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	829-78-462	According to her chart, Valarie has lost 5 pounds in the last month but states that she has not been trying to diet.

Valarie Ramirez, a 33-year-old female, arrives at the clinic for a follow-up check for the removal of a painful wart on her right hand. During the patient interview, she states she is not having trouble with her hand; however, she has noticed in the mirror that she has a lump on the front of her neck

© McGraw-Hill Education

at the bottom. She is a little hoarse but denies any other symptoms. She thought she should tell the doctor. Her vital signs are BP 122/78 T 98.8 P 88 R 20 Ht. 5' 2" Wt. 135 lb. Dr. Buckwalter orders an ultrasound of the lump with needle biopsy if indicated. He also orders blood work, including TSH and CEA tests.

Keep Valarie in mind as you study this chapter.

There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 42, you will be able to:

- 42.1** Describe the medical specialties of allergy, cardiology, dermatology, endocrinology, gastroenterology, neurology, oncology, and orthopedics.
- 42.2** Identify common diseases and disorders related to cardiology, dermatology, endocrinology, gastroenterology, neurology, oncology, and orthopedics.
- 42.3** Relate the role of the medical assistant in examinations and procedures performed in the medical specialties of allergy, cardiology, dermatology, endocrinology, gastroenterology, neurology, oncology, and orthopedics.

KEY TERMS

- | | |
|-------------------------------------|------------------------------------|
| angiography | electromyography |
| arthroscopy | intra dermal test |
| balloon angioplasty | magnetic resonance imaging (MRI) |
| benign | malignant |
| cardiac catheterization | patch test |
| colonoscopy | positron emission tomography (PET) |
| computed tomography | scratch test |
| coronary artery bypass graft (CABG) | sigmoidoscopy |
| echocardiography | stent |
| endoscopy | Wood's light examination |
| electroencephalography (EEG) | |

- I.C.8** Identify common pathology related to each body system including:
 - (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
 - (a) diagnostic measures
 - (b) treatment modalities
- I.C.11** Identify the classifications of medications including:
 - (a) indications for use
 - (b) desired effects
 - (c) side effects
 - (d) adverse reactions
- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.9** Assist provider with a patient exam
- I.A.3** Show awareness of a patient's concerns related to the procedure being performed
- V.P.4** Coach patients regarding:
 - (a) office policies
 - (b) health maintenance
 - (c) disease prevention
 - (d) treatment plan
- V. A.3** Demonstrate respect for individual diversity including:
 - (a) gender
 - (b) race
 - (c) religion
 - (d) age
 - (e) economic status
 - (f) appearance
- X.P.3** Document patient care accurately in the medical record

2. Anatomy and Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- c. Apply various medical terminology for each specialty

4. Medical Law and Ethics

- a. Follow documentation guidelines

9. Medical Office Clinical Procedures

- a. Practice standard precautions and perform disinfection/sterilization techniques
- d. Assist provider with specialty examination including cardiac, respiratory, OB-GYN, neurological, gastroenterology procedures
- e. Perform specialty procedures including but not limited to minor surgery, cardiac, respiratory, OB-GYN, neurological, gastroenterology
- j. Make adaptations with patients with special needs

► Introduction

As a medical assistant, you may choose employment in a medical specialty. This chapter introduces you to many of the specialties, their diseases and disorders, the types of exams involved, and how the medical assistant can assist with diagnostic testing. Certain specialized tests and the correct methods to administer them also are included in this chapter. As with any other practice, when working in a medical specialty, keep in mind that you also perform basic administrative and clinical skills and will have the responsibility of communicating with and educating patients. Certain concerns and questions are common to patients within a specialty area. Being

prepared to address these concerns and questions will allow you to help patients effectively and fulfill a vital role on the healthcare team.

► Working in Other Medical Specialties

LO 42.1

Licensed practitioners working in medical specialties focus on one body system (such as the skin) or a single type of disease (such as cancer). The medical specialties discussed here include allergy, cardiology, dermatology, endocrinology, gastroenterology, neurology, oncology, and orthopedics.

EDUCATING THE PATIENT

Using an Epinephrine Autoinjector

When working in a medical office that treats people with allergies, you must be familiar with epinephrine so that you can teach patients how to self-administer it. Epinephrine is a drug used to treat allergies so severe that exposure to the allergen may be life threatening. The following reactions indicate the possibility of anaphylaxis, or anaphylactic shock:

- Flushing
- Sharp drop in blood pressure
- Hives
- Difficulty breathing
- Difficulty swallowing
- Convulsions
- Vomiting
- Diarrhea and abdominal cramps

If a patient with a severe allergy experiences any or all of these symptoms, the reaction can be fatal unless emergency treatment is given immediately. So patients who cannot always control their exposure to an allergen—for example, bee or wasp venom—must have access to an epinephrine autoinjector for emergency intramuscular use. These prepackaged injectors (Figure 42-1) deliver either 0.3 mg of epinephrine—a single dose for an adult—or 0.15 mg of epinephrine—a single dose for a child. A patient who is exposed to the allergen should use the injector if the allergy is confirmed or if the allergy is suspected and signs of anaphylaxis appear. Teach the patient to follow these steps when using an autoinjector:

1. Remove the autoinjector from the packaging (box and/or plastic tube).
2. Pull back the gray cap.
3. Place the black tip of the injector on the outside of the upper thigh. (If needed, the injector can go through clothing.)

4. Press firmly into the thigh and hold for 10 seconds.
5. Remove the autoinjector and massage the injection site for a few minutes.
6. Call or have someone call 911 and go immediately to the nearest healthcare facility for follow-up care.

An autoinjector is for emergency supportive therapy only. It is not a replacement for immediate medical care. Make sure the patient is thoroughly familiar with the parts of the autoinjector, how to activate it, how to use it, and what to do next. Many injectors come packaged with a training injector for this task. If the patient is very young or otherwise unable to use the autoinjector reliably, teach a family member or companion how to use it. Additionally, “talking” autoinjectors are available and recommended for these patients.

FIGURE 42-1 Epinephrine autoinjectors come prepackaged, containing the correct amount of the drug for an adult or a child.

© Leesa Whicker

Allergy

An allergist specializes in diagnosing and treating allergies. Allergies involve inappropriate immune system responses, or allergic reactions, to normally harmless substances called *allergens*. During an allergic reaction, inflammation and tissue damage occur. Common allergens include certain foods (such as eggs and nuts), pollens, medications, insect venom, and animal saliva or dander.

Allergic reactions may show themselves locally—with a skin rash or nasal congestion—or may manifest themselves throughout the body. The most severe kind of allergic reaction is anaphylaxis, or anaphylactic shock, which is life threatening. When anaphylaxis occurs, immediate medical intervention is needed to save the patient’s life. You should know emergency medical intervention for anaphylaxis when preparing to work in an allergist’s office. You may need to teach patients who have severe allergies how to use an epinephrine autoinjector. See the *Educating the Patient* feature.

Cardiology

A cardiologist is a physician who specializes in heart diseases and disorders. To assist a cardiologist, you must be familiar with the structure of the cardiovascular system and the typical exams and measurements associated with it. You also need to know about common heart diseases and their treatments. Many diagnostic tests are performed in this specialty, including electrocardiography and stress testing. Imaging techniques, such as X-rays and **echocardiography** (see Figure 42-2), also may be employed. You will assist with or perform some of these tests. Because managing a heart condition often involves many lifestyle changes, educating the patient about topics such as diet and exercise will be especially important in this specialty. You also will provide emotional support to patients with serious illnesses.

Dermatology

Dermatologists diagnose and treat skin diseases and disorders such as acne, eczema, and skin cancer. Some skin conditions

FIGURE 42-2 An echocardiograph shows the structures and function of the heart.

© Steve Allen/Getty Images RF

involve only the skin itself; others are a sign of disease elsewhere in the body. To assist in a dermatologist's office, you must understand the basic elements of dermatologic exams and procedures. In addition to developing familiarity with skin disorders and their treatments, you also need to understand the terminology used to describe skin lesions, as outlined in the chapter *The Integumentary System*. Assisting with positioning and draping during a skin examination and taking skin scrapings or wound cultures might be among your duties in a dermatologist's office. You might perform procedures such as administering sunlamp treatments and applying topical medications. You also will instruct patients about caring for a skin condition or wound site at home.

Endocrinology

Endocrinologists treat diseases and disorders of the endocrine system, which includes glands that regulate and coordinate the body's systems. Hormonal imbalances can affect the basic processes of growth, metabolism, and reproduction. Patients with thyroid imbalances, diabetes, or menopause frequently go to endocrinologists. In the endocrinologist's office, you will assist with exams and collect specimens for analysis.

Gastroenterology

Gastroenterologists diagnose and treat disorders of the entire gastrointestinal (GI) tract, from the mouth to the anus, as well as the liver and pancreas. Proctologists are another type of GI specialists. Unlike gastroenterologists, proctologists treat disorders of the rectum and anus only. A patient who sees a GI specialist has usually been referred by a family doctor, internist, or pediatrician who suspects a GI problem requiring additional expertise. You will need to understand the basic elements of GI exams and procedures to assist in a gastroenterologist's office. You also must be familiar with common GI disorders, their treatments, and the terminology used to describe them. In a gastroenterologist's office, you will tell patients how to prepare for a **colonoscopy** and other

exams and procedures performed in the office, a radiology facility, or a hospital. Colonoscopy is discussed later in this chapter.

Neurology

Neurologists diagnose and treat diseases and disorders of the central nervous system (CNS) and associated systems. Nervous system injuries or diseases can result in loss of sensation, loss or impairment of voluntary movement, seizures, or mental confusion. Your duties in a neurologist's office include assisting with exams by readying equipment for use, positioning the patient, and handing the physician tools and other items. You may be asked to perform parts of these exams. You also may assist with certain diagnostic tests, such as **electroencephalography (EEG)** (see Figure 42-3). Your responsibilities may include instructing and educating patients and their families about procedures, disorders, and treatments.

Oncology

An oncologist specializes in the detection and treatment of tumors and cancerous growths. The term *cancer* refers to a number of oncologic diseases that affect different body systems. All cancers are characterized by the uncontrolled growth and spread of abnormal cells. A tumor is a lump of abnormal cells. Tumors are classified as **benign** or **malignant**. Benign tumors contain abnormal cells, but the cells do not invade and actively destroy surrounding tissue. Malignant tumors contain cells that grow uncontrollably, invading and actively destroying the tissue around them. Malignant, or cancerous, growths are capable of *metastasis*—the spreading of abnormal cells to body sites far removed from the original tumor. When cells become malignant, the process is called *carcinogenesis*. You will encounter patients with a variety of medical conditions in an oncologist's office, so you must be aware of the common types of cancer, what their symptoms are, and how they are treated (Table 42-1). Part of your job may involve preparing patients for the side effects of cancer treatment and helping patients deal with them. Patient and family education and support are essential.

FIGURE 42-3 Electroencephalography (EEG) is performed by placing electrodes on the patient's forehead and scalp.

TABLE 42-1 Common Cancers by System

System	Cancer Type	Symptoms	Treatment
Reproductive (female)	Breast	Lump or thickening in breast, changed appearance, discharge	Surgery (lumpectomy or mastectomy), radiation, chemotherapy
	Endometrial	Postmenopausal bleeding	Surgery, radiation, chemotherapy
	Cervical	Usually none; possible painless vaginal bleeding and an abnormal Pap smear (Papanicolaou smear)	Surgery, radiation, chemotherapy
	Ovarian	Usually none; possible abdominal pain and bloating	Surgery, radiation, chemotherapy
Reproductive (male)	Prostate	Often none; possible difficult, frequent, or painful urination	Surgery, radiation, chemotherapy
	Testicular	Lump in testicle	Surgery, radiation, chemotherapy
Respiratory	Lung (including bronchus)	Often no early symptoms; later, new cough or cold that lingers; chest, shoulder, and/or back pain; wheezing and shortness of breath; hoarseness; coughing up blood; swelling in the face and neck; difficulty in swallowing; weight loss and anorexia; increased fatigue; recurrent respiratory infections	Surgery, radiation, chemotherapy
Digestive	Colorectal	Changes in bowel habits, blood in stools, rectal or abdominal pain	Surgery combined with radiation or chemotherapy
	Liver	Abdominal pain, fatigue, jaundice	Surgery, liver transplant
	Esophageal	Often no early symptoms; later, difficulty swallowing and/or regurgitation of food	Surgery, radiation, chemotherapy
	Oral (mouth and throat)	May begin with painless sore or mass; later, difficulty chewing or swallowing	Surgery, radiation, chemotherapy
	Stomach	Indigestion, weight loss, nausea	Surgery, chemotherapy
Circulatory	Leukemia (all types)	Fatigue, paleness, repeated infections	Chemotherapy, bone marrow transplants
	Non-Hodgkin's lymphoma	Enlarged lymph nodes, itching, fever, weight loss	Chemotherapy, radiation
Urinary	Kidney (renal cell)	Blood in urine, pain in side that does not go away; lump or mass in side or abdomen; weight loss for no known reason; fever; feeling very tired	Surgery, targeted therapy, radiation therapy
	Bladder	Blood in urine; urgent need to empty bladder; urinary frequency; feeling the need to empty the bladder without results; feeling pain when emptying the bladder	Surgery, chemotherapy, biological therapy, radiation therapy
Endocrine	Thyroid	A lump in the front of the neck; hoarseness or voice changes; swollen lymph nodes in the neck; trouble swallowing or breathing; pain in the throat or neck that does not go away	Surgery, thyroid hormone therapy, radioactive iodine therapy, external radiation therapy, chemotherapy
	Pancreatic	Dark urine, pale stools, and yellow skin and eyes from jaundice; pain in the upper part of the abdomen; pain in the middle part of the back that does not go away when shifting position; nausea and vomiting; stools that float in the toilet	Surgery, chemotherapy, targeted therapy, radiation therapy
Nervous	Malignant tumors of brain and brainstem	Headaches, nausea, and vomiting; changes in speech, vision, or hearing; problems balancing or walking; changes in mood, personality, or ability to concentrate; problems with memory; muscle jerking or twitching; numbness or tingling in the arms or legs	Surgery, radiation, chemotherapy
Skeletal	Osteosarcoma (most often in knee and upper arm)	Persistent, unusual pain or swelling in or near a bone	Surgery, chemotherapy, radiation therapy, immunotherapy, cryosurgery, vaccine therapy
	Chondrosarcomas: malignant tumors of cartilage (most often in hip, femur, humerus)	Usually no early symptoms; later, patients may feel a bony bump with pain, swelling, and limited movement of the affected bone	Surgery

Source: Adapted from American Cancer Society (<http://www.cancer.org>) and National Cancer Institute (<http://www.cancer.gov>).

Orthopedics

Orthopedics is the medical specialty focusing on disorders, injuries, and diseases of the muscular and skeletal systems. The two systems are so interdependent they are sometimes referred to as the musculoskeletal system, especially by orthopedists. In an orthopedist's office, you will be asked to assist with general exams. Other responsibilities may include assisting with X-rays, helping with casting, applying hot or cold treatments, and educating patients about therapy regimens.

Diseases and Disorders of Medical Specialties

LO 42.2

The medical assistant working in medical specialties should have a basic knowledge of the diseases and disorders related to these specialties. Understanding the conditions that commonly occur in certain medical specialties will improve your ability to assist the licensed practitioner and patients.

Cardiology Diseases and Disorders

Cardiology is a common specialty practice because of the prevalence of cardiovascular diseases and disorders. Every year since 1918, the number one cause of death in the United States has been cardiovascular disease, or a disease of the heart and blood vessels. Approximately 2,500 Americans die every day from coronary artery disease (CAD)—narrowing of the blood vessels surrounding the heart that causes a reduction of blood flow to the heart. Cardiovascular disease claims more lives than the next four leading causes of death combined. Unbelievably, one of every three American adults has some form of CAD. You may know someone who has hypertension (high blood pressure) or other heart conditions. Maybe someone you know has had a myocardial infarction (MI), or heart attack. Several factors put patients at risk for heart disease, including inactivity, obesity, high blood pressure, cigarette smoking, high cholesterol, and diabetes. As a medical assistant working in a cardiology office, you should be able to teach patients about ways to reduce or prevent heart disease, stroke, and heart attack (see Table 42-2). Many of the diseases or disorders seen in a cardiology office are outlined in Table 42-3. Treatment for cardiovascular disease frequently includes medications, discussed in the *Principles of Pharmacology* chapter.

Dermatologic Conditions and Disorders

The condition of the skin plays a large part in a person's appearance. Patients with skin disorders, therefore, may worry about their attractiveness to and acceptance by others. Allow patients to express their anxieties; in return, provide encouragement about the course and outcome of their treatment. Table 42-4 discusses some of the most common dermatologic conditions and disorders. These and other diseases and disorders of the skin and accessory organs are discussed in the chapter *The Integumentary System*.

Endocrine Diseases and Disorders

The most common diseases and disorders seen in an endocrinologist's office are those related to the pancreas, thyroid, and

TABLE 42-2 Ways to Reduce or Prevent Heart Disease, Stroke, and Heart Attack

The American Heart Association now recommends that you watch your ABCs:

A. Avoid tobacco.
1. Stop smoking. A smoker's risk is twice that of a nonsmoker. Even exposure to environmental tobacco smoke (secondhand smoke, passive smoking) may increase heart disease risk.
2. Decrease stress.
3. Maintain healthy blood pressure. Find ways to lower blood pressure and to keep the numbers down. The goal is a blood pressure of less than 120/80 mmHg.
4. Maintain healthy blood cholesterol. Cholesterol will cause fat to lodge in your arteries, sooner or later causing a heart attack or stroke. Keep the total cholesterol less than 200 mg/dL.
B. Be more active.
1. Increase physical activity. The goal is to increase physical activity to 30 to 60 minutes on most days of the week. Increasing activity will decrease the following:
a. Stress
b. High blood pressure
c. High blood cholesterol
d. Obesity
C. Choose good nutrition. Maintain a well-balanced diet, which helps to decrease the following:
1. Alcohol consumption
2. Stress
3. High blood cholesterol
4. Diabetes
5. Obesity

Source: Adapted from The American Heart Association's guidelines.

reproductive organs. However, an endocrinologist would treat any disorder related to the endocrine system. Diabetes occurs when the pancreas does not secrete enough insulin or the body is resistant to insulin. A deficiency of insulin or a resistance to it interferes with the metabolism of carbohydrates, proteins, and fats, raising the glucose level in the blood. This condition is known as *hyperglycemia*. The symptoms of diabetes are often subtle and include frequent urination, excessive thirst, extreme hunger, unexplained weight loss, fatigue, and blurry vision. Common types of diabetes are Type 1, Type 2, and gestational diabetes, discussed in the chapter *The Endocrine System*. No matter the type of diabetes, the goal is basically the same: Keep blood sugar levels within a normal range, eat a healthy diet, exercise regularly, and see a healthcare provider routinely (see Figure 42-4).

Disorders related to the thyroid gland include hypothyroidism and hyperthyroidism. Hypothyroidism is characterized by decreased activity of the thyroid gland and underproduction of the hormone thyroxine. This shortage can cause cretinism in children, with resulting mental and physical disabilities. Underproduction of thyroxine in adults results in myxedema. Patients with this condition have fatigue, low blood pressure, dry skin and hair, facial puffiness, and goiter or an enlarged thyroid gland. Treatment for hypothyroidism consists of thyroid hormone supplements.

TABLE 42-3 Cardiovascular Diseases

Category of Disease/Disorder	Common Conditions*	Treatment
Arterial/vascular disorders	Aneurysm	Medication, surgery
	Arteriosclerosis	Medication, lifestyle and diet management, surgery
	Atherosclerosis	Medication, lifestyle and diet management, surgery
	Hypertension	Medication, lifestyle and diet management, stress management
	Varicose veins	Elastic stockings, weight loss, elevation of legs, surgery
Coronary artery disease	Angina pectoris	Medication, rest, lifestyle management
	Myocardial infarction	Medication, oxygen administration, rest, lifestyle management
Dysrhythmias	Atrial fibrillation	Medication, cardioversion (electric shock to the heart)
	Conduction delays or blocks (problems with electrical transmission within the heart)	Medication, pacemaker
	Tachycardia	Medication, diet management
Heart failure	Congestive heart failure	Medication, diet management, rest
	Cardiomyopathy (weakening of the heart muscle)	Medication, heart transplant
Inflammation of the heart tissue	Endocarditis (inflammation of heart lining and valves)	Medication, valve surgery
	Myocarditis	Specific treatment for underlying cause, medication, rest
	Pericarditis	Medication, rest
Valvular diseases	Aortic stenosis	Surgical replacement of valve
	Mitral stenosis	Medication, rest, valve surgery
	Mitral valve prolapse	Medication (usually antibiotic prophylaxis to prevent subacute bacterial endocarditis)

*Cardiovascular diseases and disorders are described in more detail in the chapter *The Cardiovascular System*.

Hyperthyroidism, also called Graves' disease, is characterized by increased thyroid gland activity. The patient has anxiety, irritability, elevated heart rate and blood pressure, tremors, and weight loss despite an increased appetite. Treatment includes the administration of radioactive iodine, antithyroid drugs, or surgery to remove part or all of the thyroid gland. Many patients require supplemental thyroid hormones following treatment for a hyperactive thyroid.

Gastrointestinal Diseases and Disorders

The level of discomfort from GI disorders can be misleading in relation to severity. There may be severe pain with intestinal gas, which is not serious, whereas there is virtually no pain in the initial stage of appendicitis, which is potentially life threatening. Be sure your notes are accurate and complete when a patient reports GI symptoms. Note the level of the patient's pain, whether over-the-counter (OTC) drugs have been administered, and if so, whether the OTC drugs provided any relief. Common diseases and disorders treated by a GI specialist are outlined in Table 42-5 and discussed in the chapter *The Digestive System*.

Neurologic Diseases and Disorders

Common diseases of the neurologic system are described in Table 42-6. Trauma can also cause damage to the nervous

system; such injuries can result in loss of sensation and voluntary motion. You should know the terms related to the various types of sensation loss:

- Hemiplegia: paralysis on one side of the body commonly caused by a stroke, brain or spinal cord injury, or tumor
- Paraplegia: paralysis in the lower extremities
- Quadriplegia: paralysis of the arms, legs, and all muscles below a cervical (neck) spinal injury

Encephalopathy is a term for a disease of the brain that alters brain function or structure. Encephalopathy may be caused by an infectious agent, a metabolic dysfunction, a brain tumor, increased pressure in the skull, prolonged exposure to toxic elements, chronic progressive trauma, poor nutrition, or lack of oxygen or blood flow to the brain. The most prevalent sign of encephalopathy is an altered mental state. Common neurologic symptoms of encephalopathy are progressive loss of memory and cognitive ability, slight personality changes, inability to concentrate, lethargy, and progressive loss of consciousness.

Orthopedic Diseases and Disorders

Table 42-7 lists many of the diseases and disorders you will encounter in an orthopedic specialty. For example, back

TABLE 42-4 Common Dermatologic Conditions and Disorders

Condition	Description/Symptoms	Treatment/Prevention
Acne vulgaris (acne)  © Dr. Harout Tanielian/Science Source	Inflammation of the follicles of the skin's sebaceous (oil) glands, causing skin eruptions. Pimples, blackheads, and cysts are seen on the face, back, and other areas.	Antibiotics, contraceptives, and retinoid are used to manage the outbreaks. Retinoid can damage a fetus, so it is not taken if a woman is pregnant or could get pregnant.
Contact dermatitis  © John Kaprielian/Science Source	Caused by irritants such as rough fabrics, cosmetics, pollen, or plants such as poison ivy or poison oak. Symptoms include redness, itching, edema, and lesions.	Treatment depends on the cause and type of lesions. Anti-inflammatory medications or antihistamines; oral corticosteroids are prescribed for severe inflammation.
Eczema  © Michel Jolyot/Science Source	Skin inflammation that may be an allergic response to allergens, such as chemicals or foods.	Combination of therapy and lifestyle changes to control flare-ups; oral or topical (applied to the skin) medication and phototherapy (light therapy).
Mole  © Lea Paterson/Science Source	Raised or unraised brown, black, or tan spot less than 6 mm in diameter. Has even coloring and a round or oval shape and clear borders. Monitor for bleeding, itching, or changes in color, size, shape, or texture.	May be surgically removed.
Psoriasis  (C) Biophoto Associates/Science Source	Patches of red, thickened skin with silver scales mostly found on the knees, elbows, scalp, face, palms, and soles of the feet. More common in adults than in children. Diagnosed through microscopic exam of skin scrapings.	Topical creams and ointments, light therapy, and systemic and combination therapies.
Ringworm  © Dr. Lucille K. George/CDC	Most often affects the feet (athlete's foot, or tinea pedis), groin (jock itch, or tinea cruris), and scalp (tinea capitis). Flat lesions are dry and scaly or moist and crusty, and develop a clear center with an outer ring. Creates scaly bald patches on scalp.	Topical antifungal medications; oral medications if severe. Contagious, so patient should not share bedding, combs, towels, or other personal items.
Warts (verrucae)  © Biophoto Associates/Science Source	Benign skin tumors that result from a viral skin infection. If a wart is scratched open, the virus may spread by contact to another part of the body or to another person. Several kinds: • Common warts are raised, rounded, flesh-colored lesions that usually occur on the hands and fingers. • Plantar warts appear on the soles of the feet. • Venereal warts appear on the genitalia and anus and are transmitted through sexual contact.	Treatment depends on the type of wart. Some warts go away without treatment. Removed by burning or freezing the wart tissue. Instruct the patient to keep the wart removal site clean and dry until a scab forms or the wart falls off.

(continued)

TABLE 42-4 Common Dermatologic Conditions and Disorders

Condition	Description/Symptoms	Treatment/Prevention
Skin Cancer		
Basal cell carcinoma  © Dr. P. Marazzi / Science Source	Risk factors: overexposure to the sun, X-rays, irritants, various chemical carcinogens, presence of premalignant lesions. Most common are malignant basal cell carcinomas on areas exposed to the sun, such as the face and neck. Higher-than-average risk of developing skin cancer: those who have had severe, blistering sunburns in their teens or 20s; those who have fair skin and hair and light-colored eyes; and those who work outdoors.	Treatments for skin cancer vary with the type of cancer and its extent. Treatments include surgery, electrosurgery, cryosurgery, radiation therapy, and chemotherapy.
Squamous cell carcinoma  © Biophoto Associates/Science Source	Appears on sun-exposed areas and looks ulcerated or has a crust. Invades deeper into the skin and has a greater tendency to spread to other body areas.	Treatments for skin cancer vary with the type of cancer and its extent. Treatments include surgery, electrosurgery, cryosurgery, radiation therapy, and chemotherapy.
Malignant melanoma  © Tom Myers/Science Source	Originates in cells that produce the pigment melanin; this is the most dangerous type of skin cancer. Malignant cells may spread through the bloodstream or lymphatic system to the liver, lungs, and other parts of the body. A sudden or continuous change in the appearance of a mole may signal melanoma.	Treatments for skin cancer vary with the type of cancer and its extent. Treatments include surgery, electrosurgery, cryosurgery, radiation therapy, and chemotherapy.

pain—especially lower back pain—is a common disorder. It can have many causes, including muscle strain, osteoarthritis, and the presence of a tumor. Treatments include the application of heat, the administration of analgesics or muscle relaxants, exercise therapy, special braces, traction, and surgery.

Another condition commonly encountered in the orthopedist's office is a fracture, or break in a bone. Fractures and their treatment are discussed in detail in the *Emergency Preparedness* chapter.

► Exams and Procedures in Medical Specialties

LO 42.3

As a medical assistant, understanding the anatomy and physiology of various body systems and the specific exam and procedural steps for each specialty area is key. Most specialists' offices have a procedure manual for you to use as a reference when learning new procedures. You will assist with exams and procedures and perform certain procedures on your own. This section will introduce you to basic exams and procedures performed in medical specialties.

Allergy Exams and Testing

An allergy exam involves a medical history and, usually, several diagnostic tests. You may assist with these tests or perform them yourself under a licensed practitioner's supervision. Skin tests, for example, involve introducing solutions containing suspected allergens onto or just below the skin. Any reaction is observed and assessed.

Allergy treatments include allergen avoidance, medications, and desensitization to a substance by means of injections. Part of your job will be to encourage patients to make necessary lifestyle changes to avoid allergens. See *Educating the Patient: Creating a Dust-Free Environment*. You also will help patients adhere to regimens of injections or medication.

TABLE 42-5 Common Gastrointestinal Diseases and Disorders

Condition*	Description	Treatment
Anal fissure	Ulcer in anal wall; may develop into fistula (an abnormal duct to the rectum)	Depends on extent; may require surgery to repair
Cholecystitis	Inflammation of the gallbladder caused by gallstones, tumor, or bile duct blockage; symptoms are pain, nausea, diarrhea	Avoidance of fatty foods if intolerant; lithotripsy to break up stones; antibiotic for bacterial infection
Cholelithiasis	Gallstones	Lithotripsy, antibiotics to prevent secondary infection or a cholecystectomy (removal of the gallbladder)
Colitis	Inflammation of the colon caused by bacteria, food intolerance, anxiety, or emotional disorder	Diet modification (clear liquid for acute phase), medication, psychotherapy, fluid replacement, colostomy for severe cases
Constipation	Having fewer than three bowel movements a week along with hard feces that are difficult and painful to pass.	Diet modification, stool-softener medication, enema, surgery if necessary for impaction
Diarrhea	Abnormally frequent, watery bowel movements	Diet modification, antibiotics for bacterial infection, fluids and medication to prevent dehydration
Diverticulitis	Inflammation of diverticulum	Diet modification, surgery for severe cases
Gastritis	Inflammation of stomach lining	Diet modification, drug therapy
Gastroesophageal reflux (GERD)	Gastric acid rising from stomach into esophagus	Diet modification, small meals, antacids, upright eating, remaining upright for several hours after eating, surgery (rarely)
Hemorrhoids	Enlargement of rectal or anal veins	Diet modification, surgery
Hernia	Organ pushes through a muscle or wall containing it; common abdominal hernias include hiatal hernia and inguinal hernia	Surgery to repair muscle
Stomatitis (canker sores)	Sore gums or other oral areas caused by herpes virus or acidic body chemistry; exacerbated by emotional distress, acidic foods; symptoms are ulcerations (canker sores) with burning, sometimes swelling	Bland diet, avoidance of stress, medicated mouth rinses, topical anesthetic

* Gastrointestinal diseases and disorders are described in more detail in the chapter *The Digestive System*.

TABLE 42-6 Common Diseases of the Neurologic System

Condition*	Description	Treatment
Alzheimer's disease	Disabling disease that involves dementia and deterioration of physical function	Frequent stimulation to possibly help slow deterioration, and medications that may slow progression of some symptoms
Bell's palsy	Disease that causes sudden weakness or paralysis on one side of the face because of damage to the facial nerve	Usually resolves without treatment in 1 to 8 weeks
Encephalitis	Inflammation of brain tissue usually caused by viral infection; symptoms: fever, headache, vomiting, stiff neck, drowsiness	Medication, rest
Epilepsy	Disease caused by misfiring of nerve groups in the brain, resulting in seizures	Medication
Herpes zoster	Disease caused by the virus that causes chickenpox; symptoms: painful blisters that form along path of one or more nerves	Medication to relieve pain
Meningitis	Inflammation of the meninges	Antibiotics and drugs to reduce swelling
Migraine headaches	Severe headaches caused by vascular disturbance	Medication
Multiple sclerosis	Degenerative disease of the central nervous system	Anti-inflammatory medications
Neuritis	Inflammation of one or more nerves; symptoms: severe pain and discomfort or paralysis of the affected area	Medication and rest
Parkinson's disease	Progressive neurological disease	Medication to relieve symptoms
Sciatica	Inflammation of the sciatic nerve	Medication to relieve pain, rest, heat applications

* Neurologic diseases and disorders are described in more detail in the chapter *The Nervous System*.

TABLE 42-7 Common Diseases and Disorders of the Musculoskeletal System

Condition*	Description	Treatment
Arthritis	Inflammation of joints	Anti-inflammatory medications, heat, rest, exercise, occupational and physical therapy, surgery (arthroplasty)
Bursitis	Inflammation of one or more bursae (sacs surrounding joints)	Anti-inflammatory medications
Carpal tunnel syndrome	Compression of the median nerve, causing wrist pain and numbness	Rest and occupational adjustments, splinting of wrists, injection of corticosteroids, surgical decompression of nerve
Dislocation	Displacement of bones at joint so that parts that are supposed to make contact no longer come together; occurs most often to fingers, shoulder, knee, and hip	Relocation, or shifting bones back into place; anti-inflammatory medications
Herniated intervertebral disk (HID)	Protruding contents of disk compress nerve roots, causing severe pain	Rest, traction, physical therapy, muscle relaxants, surgery
Osteomyelitis	Infection of bone; principal symptom is pain	Antibiotics and analgesics, surgery
Osteoporosis	Decreased bone mass, resulting in brittle, easily fractured bones	Exercise, dietary supplements, hormone therapy, drug therapy
Paget's disease	Chronic condition that causes bone deformities	Exercise, dietary supplements, hormone therapy, drug therapy
Scoliosis	Abnormal curving of spine	Back brace, surgery
Sprain	Injury to ligament caused by joint overextension	Rest, support, application of cold, anti-inflammatory medications
Tendonitis	Inflammation of tendon	Rest, support, anti-inflammatory medications

* Musculoskeletal diseases and disorders are described in more detail in the chapters *The Skeletal System* and *The Muscular System*.

Three tests are commonly performed in the allergist's office: the **scratch test**, the **intradermal test**, and the **patch test**. The *radioallergosorbent (RAST)* test is performed in a laboratory. Prior to a scratch, patch, or intradermal test, patients are asked to stop taking antihistamines and steroids. These medications could interfere with the test results. The RAST test has the advantage of allowing patients to continue to take antihistamines to control their allergies while being tested.

Scratch Test A scratch test tests the patient for specific allergies. Extracts of suspected allergens are applied to the patient's skin, usually on the arms or back. One site is always a negative control—a solution like the one used to carry the allergens but containing no allergen is applied. Then the skin is scratched to allow the extracts to penetrate. A scratch test may be performed using sterile needles or lancets. Some allergists prefer to use applicators that allow the tester to apply allergens to and puncture the skin in several places at once, as shown in Figure 42-5. Be sure to let the patient know the procedure may cause some discomfort and that itching afterward can be relieved with cold packs. See Procedure 42-1 at the end of this chapter. The licensed practitioner interprets the test results. Because a delayed reaction is possible, the practitioner may wish to recheck the scratch sites in 24 hours. When the results of the scratch test are inconclusive, another test, such as an intradermal test, may be ordered.

Intradermal Test This test introduces dilute solutions of allergens into the skin of the inner forearm or upper back with

a fine-gauge needle. The intradermal test is more sensitive than the scratch test. A small blister, also known as a wheal, which is filled with the introduced fluid, appears on the skin over the injection site. The allergic reaction time is about 15

EDUCATING THE PATIENT

Creating a Dust-Free Environment

Patients with household dust allergies will need to reduce their dust exposure as much as possible. One way they can do this is to keep their environment, especially their bedroom, as clean as possible. Share these guidelines from The National Institute of Allergy and Infectious Diseases with your patients.

- Prepare the room by removing all contents, cleaning and scrubbing all woodwork, removing carpeting and drapery (if possible), and closing doors and windows. Maintain the room by cleaning it thoroughly once a week. This includes floors, the tops of doors, and windowsills and frames. Use a special vacuum filter and wash any curtains often.
- Keep the bed and bedding as dust free as possible by encasing box springs and mattress in a dustproof cover and washing all pajamas in 130°F water.
- Keep furniture in the room to a minimum, use furnace air filters (high-efficiency particulate absorption [HEPA] filters are best), avoid stuffed animals, and keep pets out of the bedroom.

FIGURE 42-5 A multiple applicator allows the medical assistant to apply several allergens at one time.

© Science Photo Library/agefotostock RF

to 30 minutes, although some substances may cause delayed reactions. If no reaction appears, the test can be repeated with a more concentrated solution to confirm the result. If a severe reaction occurs, the licensed practitioner will order epinephrine to be administered.

The tuberculin test, or purified protein derivative (PPD) test, is a type of intradermal skin test. An extract from the tubercle bacillus is injected into the skin. The results are read in 48 to 72 hours. Raising and hardening of the skin around the area (induration), rather than redness alone, indicate a positive reaction. The procedure for administering an intradermal injection is found in the *Medication Administration* chapter.

Patch Test You perform a patch test by placing a linen or paper patch on uninvolved skin and then using a dropper to soak the patch with the suspected allergen (Figure 42-6). Cellophane or another occlusive material, usually covered with an adhesive patch, is then applied over the linen or paper patch. Among other things, this test is used to discover the cause of contact dermatitis.

Radioallergosorbent Test (RAST) The RAST measures blood levels of antibodies to specific allergens. You

FIGURE 42-6 A patch test is usually done on the arm and is read in 48 hours.

obtain a blood sample from the patient and send it to a laboratory. There, the blood serum is exposed to suspected allergens and the levels of antibodies are measured. This test usually provides more information than skin testing but is more expensive.

Cardiology Exams

A general cardiovascular exam usually begins with a blood pressure reading and an evaluation of overall cardiac health. The cardiologist also palpates the chest wall and the vessels in the extremities to detect abnormal vibrations, pulses, swelling, or temperature. In addition, an electrocardiogram may be obtained.

Electrocardiogram An electrocardiogram (ECG or EKG) provides a measurement of the heart's electrical activity. Electrocardiography—a routine part of a cardiovascular exam—is a painless and safe diagnostic test. Electrodes are placed on the skin in particular areas of the chest and limbs. The heart's electrical activity is shown as a tracing on a strip of graph paper. Review the full procedure for performing an ECG in the *Cardiovascular and Respiratory Testing* chapter.

Stress Test An exercise stress test involves recording an ECG while the patient is exercising on a stationary bicycle, treadmill, or stair-stepping ergometer (see Figure 42-7). This test measures the patient's response to a constant or increasing workload. Part of your job may involve keeping the equipment properly maintained and calibrated. You also may be responsible for administering the test itself, but a licensed practitioner should always be present because of the risk of cardiac

FIGURE 42-7 A stress test measures the electrical activity of the heart under a constant or increasing amount of exertion.

© BSIP/Newscom

crisis. Before the test, the patient has a screening appointment with the licensed practitioner, during which you take a careful medical history and explain pretest requirements. On the day of the test, be sure the patient has followed pretest directions, such as abstaining from smoking or consuming alcohol, and has signed the proper consent form. The patient is prepared as for an ECG by having electrodes attached to the skin. Show the patient how to use the exercise device. Review additional information regarding exercise electrocardiography (stress testing) in the *Cardiovascular and Respiratory Testing* chapter.

Variations on the basic stress test are the chemical stress test and the nuclear stress test. Chemical stress tests are performed when a patient is unable to perform the physical exercise required by a basic stress test. A chemical that mimics the effect of exercise on the heart is injected through an IV line. A nuclear stress test is similar to a chemical stress test, except that radioactive tracers (radionuclides) are injected so that the licensed practitioner can trace the path of blood through the heart.

Holter Monitor This is an ECG device that includes a digital recorder, allowing readings to be taken over a specific period of time. Electrodes are attached to the patient's chest in the licensed practitioner's office. Lead wires are attached to the electrodes and to the portable recording device, which the patient wears on a belt or sling (Figure 42-8). The patient returns home, and the device monitors heart activity for 24 or more hours. Review additional information regarding ambulatory electrocardiography (Holter monitoring) in the *Cardiovascular and Respiratory Testing* chapter.

Radiography and Imaging Techniques

Various radiographic techniques are used in cardiology. Chest X-rays can reveal conditions such as cardiac enlargement. In radionuclide studies, the patient ingests or is injected with a radioactive contrast medium, often referred to as a dye. X-rays are then taken. For example, fluoroscopy studies are X-ray exams

in which a contrast medium is injected and pictures of the heart in motion are projected onto a closed-circuit television screen. A venogram allows evaluation of the deep veins of the legs. **Angiography** is an X-ray examination of a blood vessel after the injection of a contrast medium. The test, performed in a hospital, evaluates the function and structure of one or more arteries.

Ultrasound, a noninvasive diagnostic method, is also used in cardiology. Doppler ultrasonography tests the body's main blood vessels for conditions such as weaknesses in vessel walls or blocked arteries. With the use of a handheld probe, sound waves are transmitted through the skin and are reflected by the blood cells moving through the blood vessels.

FIGURE 42-8 A Holter monitor allows the licensed practitioner to assess heart function during periods of normal activity.

© Sheila Terry/Science Source

Echocardiography tests the structure and function of the heart through the use of reflected sound waves, or echoes. Sound waves of an extremely high frequency are projected through the chest wall into the heart and are reflected back through a mechanical device. The echoes, recorded on paper or video, can indicate conditions such as structural defects and fluid accumulation.

Heart magnetic resonance imaging (MRI) is a diagnostic procedure that uses strong magnets and radio waves to produce images of the heart. This procedure is noninvasive and does not use ionizing radiation, so it is safer than other imaging techniques. Detailed pictures of the heart and heart vessels can be obtained using heart MRI.

Cardiac catheterization is an invasive diagnostic method in which a catheter (a slender, hollow tube) is inserted into a vein or an artery in the right or left arm or leg and passed through the blood vessels into the heart. The cardiologist can use this method to take blood samples for analysis, measure the pressure in the heart's chambers, and view the heart's motions with the aid of fluoroscopy. During cardiac catheterization, the cardiologist may choose to perform a **balloon angioplasty** to open partially blocked coronary arteries. This procedure involves passing a slender, hollow tube through the artery at the blockage site. The balloon at the end of the tube is then inflated, compressing the blockage and widening the artery. A metal mesh tube known as a **stent** may be placed in the artery in order to keep it open. These stents are usually coated with medications that prevent the reclosure of the blood vessel.

If the blockage is extensive, the patient may need surgery known as **coronary artery bypass graft (CABG)**, which involves bypassing the blockage with a vessel taken from another area. All of these procedures are performed in the hospital.

Dermatology Exams

During a whole-body skin examination, the dermatologist examines the visible top layer of the entire surface of the skin, including the scalp, the genital area, and the areas between the toes. The physician uses a magnifying lens and a bright light to look for lesions, especially suspicious moles or precancerous growths. Your role in this exam includes preparing patients and helping them into the proper position before examining each skin area. During the exam, drape patients to protect their privacy as much as possible while exposing the area to be examined. The physician also may ask you to take photographs or make sketches of lesions to aid in detecting future changes.

Another type of dermatologic exam is the **Wood's light examination**, in which the licensed practitioner inspects the patient's skin under an ultraviolet lamp in a darkened room. This examination highlights certain abnormal skin characteristics and aids in diagnosis. The dermatologist also may perform more limited, focused exams to evaluate specific skin conditions or disorders.

Endocrine Exams and Tests

Before an exam, you will take a thorough medical history. The licensed practitioner will assess the patient's skin condition, weight, and cardiac functioning for clues about illness. An endocrinologist will perform a complete physical exam,

including palpation of glands. Most of the endocrine glands are located deep within the body; only the thyroid, the testes, and, to some extent, the ovaries can be examined with palpation or auscultation. Therefore, you may need to collect specimens for essential diagnostic urine and blood tests.

Other diagnostic tools used in endocrinology include radiologic tests such as X-rays and iodine scans. In a thyroid scan, the patient receives an oral or intravenous (IV) dose of radioactive iodine, and the thyroid is X-rayed as the material is absorbed. Ultrasound also can be employed to view glands or detect tumors. Urine and blood may be tested for the presence of glucose or hormones.

Gastrointestinal Exams

The gastroenterologist's examination of the patient's GI tract covers the mouth (lips, oral cavity, and tongue), the abdomen and lower thorax, the lower sigmoid colon, the rectum, and the anus. Depending on the patient's symptoms, the physician may perform an invasive exam procedure during the patient's first visit. Formerly, such procedures were performed only in hospitals or special medical facilities. Now, many GI specialists' offices are equipped for these procedures and the management of possible resulting emergencies.

You must prepare the patient, provide reassurance during exams, and help patients be as comfortable as possible. Your duties during the procedures will vary according to your state's scope of practice and the physician for whom you work. Instruct patients in advance to arrange for someone to drive them to and from the exam. After a procedure in which patients have had a local anesthetic at the back of the throat, caution them to avoid eating until the drug has been eliminated from the body. Otherwise, they could choke or aspirate food particles into the trachea.

Endoscopy Endoscopy generally refers to any procedure in which a scope is used to visually inspect a canal or cavity within the body. Most endoscopic exams are performed with a flexible fiber-optic tube that has a lighted instrument on the end. These exams provide direct visualization of a body cavity and a means for collecting tissue biopsies and removing polyps, as in the colon. Endoscopy helps diagnose tumors, ulcers, structural abnormalities, and other problems. It is particularly useful in performing procedures that formerly would have required an incision, such as removing stones from the bile duct.

Peroral Endoscopy Peroral endoscopy involves inserting the scope by way of the mouth (Figure 42-9). The patient is sedated and the gag reflex is inhibited with a local anesthetic. The peroral endoscopic procedures include esophagoscopy (esophagus only), gastroscopy (stomach only), duodenoscopy (duodenum only), and panendoscopy (esophagus, stomach, and duodenum), also referred to as an EGD (esophagogastroduodenoscopy).

Colonoscopy Colonoscopy—performed by inserting a colonoscope through the anus—can provide direct visualization of the large intestine. The gastroenterologist uses this procedure to determine the cause of diarrhea, constipation,

FIGURE 42-9 To perform a peroral endoscopy, the physician inserts a scope through the patient's mouth.

bleeding, or lower abdominal pain. A colonoscopy also is performed on patients over 50 to screen for abnormal growths called polyps that can lead to colon cancer.

Patient preparation is designed to clear the colon of fecal material so that the colon can be seen clearly. The type of preparation varies depending on the practice where you are working. For example, one regimen requires the patient to follow a liquid diet for 24 to 48 hours before the procedure, then take a cathartic on the two evenings prior to the colonoscopy. Patients may also need to use one or more prepackaged enema preparations the night before and the day of the procedure. Teach the patient the colon cleansing regimen and then tell him to expect diarrhea and possibly mild cramps.

Immediately before the procedure, instruct patients to empty the bladder. Patients should be given a sedative or an analgesic before undergoing the procedure. Patients lie in the Sims' position as the scope is guided through the large intestine. The licensed practitioner may manipulate the abdomen to facilitate passage of the scope.

Proctoscopy *Proctoscopy* is an examination of the lower rectum and anal canal. After an initial digital exam, the proctoscopy is performed with a 3-inch instrument called a proctoscope. This exam can detect hemorrhoids, polyps, fissures, fistulas, and abscesses.

Sigmoidoscopy *Sigmoidoscopy* is similar to colonoscopy, except that only the sigmoid area of the large intestine (the S-shaped segment between the descending colon and the rectum) is examined. Sigmoidoscopy also aids in diagnosing colon cancer, ulcerations, polyps, tumors, bleeding, and other lower intestinal problems. Patient preparation involves using one or two prepackaged enemas either the night before or the morning of the procedure, depending on the physician's instructions. The method for assisting the physician during a sigmoidoscopy is described in Procedure 42-2 at the end of this chapter.

Diagnostic and Laboratory Testing A GI specialist may order laboratory tests to determine the presence of

bacteria or bleeding in the stomach. GI specialists may also test the feces for occult, or hidden, bleeding from the intestinal tract. This is discussed in the *Collecting, Processing, and Testing Urine and Stool Specimens* chapter.

Gastroenterologists sometimes use imaging techniques, such as X-rays, ultrasound, radionuclide imaging, computed tomography (CT), and magnetic resonance imaging. Most GI radiologic exams are not performed in an office, but you should know enough about them to answer patients' questions. Generally, these exams are performed in a hospital X-ray laboratory or an outpatient facility. You may be responsible for scheduling tests at such facilities for patients. You also may help prepare the patient for these exams. However, in some cases, the patient should discuss specific preparation with personnel from the other facility.

Gallbladder Function Test *Cholecystography* is an older gallbladder function test performed by X-ray with a contrast agent. The patient swallows tablets of the contrast agent the night before the test. X-rays taken 12 to 14 hours later should show the contrast agent in the gallbladder. The patient then swallows a substance high in fat, which should make the gallbladder contract and empty the contrast agent into the duodenum.

Cholescintigraphy, also known as a HIDA scan test, uses a radioactive chemical injected into a vein. The test chemical then disperses everywhere that the bile goes—into the bile ducts, the gallbladder, and the intestine. A special camera is used to visualize where the chemical is dispersed to determine the functioning of these organs. See the *Diagnostic Imaging* chapter for more information.

Ultrasound Ultrasound is used commonly for diagnosing problems in the gallbladder, pancreas, spleen, and liver. The patient should have nothing to eat or drink after midnight of the night before and on the morning of the exam. Some gastroenterologists perform ultrasound exams in the office.

Barium Swallow The barium swallow (also called an upper GI series) is used to detect abnormalities in the esophagus, stomach, and small intestine. The patient swallows a liquid containing barium—an insoluble contrast agent. This material is viewed using fluoroscopy (moving X-ray images) as the liquid is swallowed and passes into the stomach. X-ray films are taken at frequent intervals to record the diagnostic images. The patient is asked to move into various positions while the barium is tracked through the small intestine. To prepare for this test, the patient should have nothing to eat or drink after midnight the night before and on the morning of the procedure. Refer to the *Diagnostic Imaging* chapter for more information.

Barium Enema A barium enema (also called a lower GI series) is used to detect abnormalities in the large intestine. Barium is given as an enema in this test. A balloon-like tube is inflated in the rectum during the X-ray and the patient is asked to move into various positions to ensure that the barium is distributed completely (Figure 42-10). Patients must eat no meats or vegetables for 1 to 3 days before the test to avoid

FIGURE 42-10 During a barium enema, the barium is tracked on X-rays.

© Jim Wehtje/Getty Images RF

incorrect indications on the X-ray. For 24 hours before the test, they must also follow a liquid diet, which includes drinking special liquid laxative preparations and more than a quart of water. Specific steps vary depending on the facility, but the intent is to cleanse the colon completely. See the *Diagnostic Imaging* chapter for more information.

Radionuclide Imaging Radiology subspecialists trained in nuclear medicine perform nuclear medicine studies with radionuclide imaging. The patient is first injected with a radioactive substance, then waits a prescribed length of time for the radioactive substance to be taken up by the body part being imaged. The patient is scanned or photographed with a gamma camera, which can read the radioactive areas to determine abnormalities in their composition. This technique is commonly used for liver, spleen, thyroid, and bone scans.

Neurologic Exams and Diagnostic Testing

The neurologist evaluates five categories of neurologic function in a complete exam:

- Cognitive function (mental status)
- Cranial nerves
- Motor system
- Reflexes
- Sensory system

Cognitive function can be assessed by observing general appearance and grooming as well as by asking patients specific questions. The neurologist also determines the status of the cranial nerves, which affect smell and taste, eye movements, hearing, voice quality, facial expression, and facial mobility. The physician may, for example, ask patients to close their eyes and then identify familiar smells. The neurologist observes patients' faces for symmetry of movement and tests visual and auditory acuity. The physician assesses motor ability by testing

coordination, observing gait, and determining muscle strength. Finally, the neurologist tests patients' reflexes and examines the function of the sensory system in areas of tactile sensation, pain and temperature sensitivity, and awareness of vibration. You are likely to assist the physician in completing these exams, and you may perform certain components yourself.

Common diagnostic tests in neurology include electroencephalography and various radiologic tests. You may assist in performing these tests. Invasive tests may not be done at the physician's office. In such cases, you will need to schedule the procedures, instruct patients about pretest preparations, and educate them about the procedure and what to expect.

Electroencephalography Electroencephalography records the electrical activity of the brain on a strip of graph paper. The tracing is an electroencephalogram (EEG). Electrodes are attached to the patient's scalp and readings are taken while the patient is at rest and engaged in specific activities. An EEG can be used to detect or examine conditions such as tumors, seizure disorders, or brain injury. You may assist with electrode placement or, after training, obtain the EEG on your own.

Imaging Procedures Several imaging techniques are used as neurologic diagnostic tools. Types of procedures include angiograms, brain scans, CT, MRI, myelography, and skull X-rays.

Cerebral Angiography Cerebral angiography (or angiogram) is a radiologic study of the cerebral blood vessels. After a contrast medium is injected into an artery, X-rays are taken to visualize the cerebral blood vessels.

Brain Scan A brain scan is performed by injecting the patient with radioisotopes and, after a period of time, using a scanner to detect the material. The radioisotopes tend to gather in areas of abnormality, such as tumors or abscesses.

Computed Tomography Computed tomography, often called a CT scan, is a radiographic exam that produces a three-dimensional, cross-sectional view of the brain. Often one scan is done without a contrast medium. Then a contrast medium is injected for greater clarity. CT scans can help diagnose a wide range of conditions, including tumors, blood clots, and brain swelling.

Magnetic Resonance Imaging Magnetic resonance imaging (MRI) is a viewing technique that enables licensed practitioners to see areas inside the body without exposing the patient to X-rays or surgery. The procedure, which takes 30 to 60 minutes, requires the patient to lie still on a padded table that is moved into a tunnel-like structure. A powerful magnetic field produces an image of internal body structures. Patients who are unable to tolerate being inside a tunnel-like structure can be examined with an MRI scanner that has a more open structure (Figure 24-11).

Positron Emission Tomography Positron emission tomography, often called a PET scan, studies the blood flow and metabolic activity in the brain to help licensed

FIGURE 42-11 Magnetic resonance imaging is used to diagnose disorders in many specialties.

© Plush Studios/Getty Images RF

practitioners identify certain neurologic and CNS disorders. These disorders include Parkinson's disease, multiple sclerosis, Alzheimer's disease, transient ischemic attack (TIA), amyotrophic lateral sclerosis (ALS), Huntington's disease, epilepsy, stroke, cancer, and schizophrenia.

Myelography *Myelography* is an X-ray visualization of the spinal cord after the injection of a radioactive contrast medium or air into the spinal subarachnoid space (the space between the second and innermost of three membranes covering the spinal cord). Although an MRI is used more frequently, myelography can reveal tumors, cysts, spinal stenosis, and herniated disks.

Skull X-Ray Skull X-rays may be used to detect fractures in the skull and to locate tumors.

Other Tests Other diagnostic tests—including lumbar puncture and electromyography—do not involve imaging techniques. A lumbar puncture, or spinal tap, involves collecting a sample of cerebrospinal fluid (CSF) to diagnose infection, measure CSF pressure, and check for blood cells and proteins in the fluid. A needle is inserted between two lumbar vertebrae and into the subarachnoid space. The collected fluid is sent to a laboratory for analysis. **Electromyography** is used to detect neuromuscular disorders or nerve damage. Needle electrodes are inserted into some of the patient's skeletal muscles. When the muscles contract, a monitor records the nerve impulses and measures conduction time.

Oncology Exams and Diagnostic Testing

An exam in an oncologist's office focuses on the area of the body where a problem is suspected. The oncologist's goal is to detect, diagnose, and treat cancer, which is done through a variety of procedures. You will schedule some of these tests and provide pretest instructions and explanations to patients.

A biopsy is a common procedure an oncologist may perform, and you may assist with the procedure. There are several types of biopsies. A physician performs an incisional, or open, biopsy by making an incision and removing a piece of

tissue. A needle biopsy is performed by removing tissue with a needle inserted through the skin into the growth or area. Needle aspiration is performed by removing fluid from a lump or cyst with a needle. Procedure 42-3, at the end of this chapter, describes the steps in assisting with a needle biopsy. During a biopsy, standard precautions and sterile technique must be maintained. Always place the specimen in a prepared, labeled container provided by the laboratory. Transport it according to laboratory instructions, attaching the proper accompanying forms. After the biopsy, you might assist with or perform the cleaning and bandaging of the site.

In addition to a biopsy, you may obtain blood specimens for some tests and assist in other diagnostic procedures, such as the following:

- X-rays
- CT scans
- MRIs
- Blood tests, especially those to detect tumor markers, such as carcinoembryonic antigen (CEA) (increased levels of CEA indicate a variety of cancers), CA125, and CA15-3
- Ultrasonography

Cancer Treatment

Cancer treatments fall into three general categories: surgery, radiation therapy, and chemotherapy. Often, a combination of these treatment methods is used. All methods damage healthy as well as cancerous cells. The success of treatment depends on many factors, and recovery varies greatly from patient to patient.

Surgery Surgical removal of the tumor and some surrounding tissue is one method of cancer treatment. It is most effective when the tumor appears to be contained within a particular organ or is localized in an area of the skin. Surgery is often followed, however, by either radiation therapy or chemotherapy.

Radiation Therapy Radiation therapy uses radiation to kill and stop the growth of tumor cells. It is often used in conjunction with surgery or chemotherapy. Radiation therapy is effective because, although radiation affects all living cells, it has the most damaging effect on cells that are undergoing rapid division, including cancer cells.

Chemotherapy Chemotherapy is also used in conjunction with other therapies. Chemotherapy is the use of strong anticancer drugs to kill malignant cells. As with radiation therapy, rapidly dividing cells, such as like cancer cells, are most strongly affected by these medications. A variety of chemotherapy drugs are available, each with slightly different mechanisms of action. Table 42-8 lists common classes of chemotherapy drugs and outlines their major categories, their mechanism of action, and some examples in each category. These drugs may be used alone or in combination, depending on the type of cancer being treated. Although it is unlikely you will prepare or administer anticancer drugs, you need to

TABLE 42-8 Chemotherapy Drugs		
Category	Mechanism of Action	Examples
Alkylating agents	Hinder cell division	Chlorambucil, cyclophosphamide
Antimetabolites	Interfere with folic acid and nucleic acid synthesis	Methotrexate, fluorouracil
Antibiotics	Break DNA strands	Actinomycin, bleomycin
Antimitotic agents	Affect cell division	Vinblastine, paclitaxel

be aware that they are highly toxic. General protective guidelines, including using PPE, must be followed whenever there is risk of contact with the drugs or patients' body fluids.

Orthopedic Exams and Procedures

An orthopedist uses inspection, palpation, and diagnostic tests to assess the structure and function of the musculoskeletal system. The patient is asked to stand, walk, and perform several range-of-motion exercises. The physician notes the degree of mobility the patient has, in some cases using a device called a *goniometer*. A complete exam takes some time, and you may need to help drape, position, or physically support the patient, especially if the patient is elderly or incapacitated. You also may be responsible for instructing the patient about care for a musculoskeletal condition, including how to perform therapeutic exercises.

Orthopedists use a variety of diagnostic tests. Bone and muscle biopsies may be performed to detect disorders such as bone infection and muscle atrophy. Electromyography is another diagnostic tool used in this specialty. An orthopedist also may order urine and blood tests to detect levels of substances such as calcium or phosphorus.

As in most other specialties, X-rays play a vital role in diagnosis and may be performed in the orthopedist's office. X-rays are especially useful in determining the nature and extent of a bone injury. Other common radiographic exams in the orthopedic specialty include the following:

- CT scan
- MRI
- Angiography (for affected vascular structures)

FIGURE 42-12 Arthroscopy can be used for diagnosis as well as biopsy and surgical repair.

© Royalty-Free/Corbis

- Myelography (for spinal disorders)
- Diskography (for intervertebral disk disorders)
- Arthrography (for joint disorders)
- Bone scans

These procedures are discussed in more detail in the *Diagnostic Imaging* chapter.

Arthroscopy enables the orthopedist to see inside a joint—usually the knee, shoulder, or hip—with an arthroscope. This tubular instrument includes an optical system; when the tube is inserted into the joint, it can be visualized (Figure 42-12). Arthroscopy is used to give the physician a closer look at conditions such as injuries and degenerative joint diseases and to guide surgical procedures.

Joint replacement surgery is often used to treat knee and hip joints severely damaged by arthritis, disease, or injury. Hip replacement may be indicated in cases of severe arthritis pain, femoral neck fractures, or hip joint tumors. Knee pain that does not respond to medications or physical therapy or a knee damaged by severe arthritis may indicate the need for knee replacement. Both surgeries require that the damaged joint be removed and an artificial joint inserted in its place. Physical therapy is usually started soon after surgery, and most patients fully recover in 3 to 12 months.

PROCEDURE 42-1 Assisting with a Scratch Test Examination

WORK // DOC

Procedure Goal: To assist a licensed practitioner in determining substances to which a patient has an allergic reaction

OSHA Guidelines:

Materials: Patient chart/progress note, disposable sterile needles or lancets, allergen extracts, control solution, cotton balls, alcohol, timer, adhesive tape, ruler, cold packs or an ice bag

Method:

1. Wash your hands and assemble the necessary materials.
2. Identify the patient and introduce yourself.

3. Show the patient into the treatment area. Explain the procedure and discuss any concerns. Confirm whether the patient followed pretesting procedures such as discontinuing medications.
RATIONALE: *Antihistamines and steroids may interfere with the test.*
4. Assist the patient into a comfortable position and don exam gloves.
5. Swab the test site, usually the upper arm or back, with an alcohol prep pad.
6. Identify the sites with tape labels.
RATIONALE: *The sites must be easily identified so that you can record reactions to individual antigens.*

FIGURE Procedure 42-1 Step 6 Label each site with the name of the allergen or an accepted abbreviation.
© John Radcliffe/SPL/Science Source

7. Apply small drops of the allergen extracts and control solution onto the test site at evenly spaced intervals, about 1½ to 2 inches apart.
8. Open the package containing the first needle or lancet, making sure you do not contaminate the instrument.
9. Assist the licensed practitioner with the scratch procedure or perform the procedure if it is within your scope of practice. Using a new sterile needle or lancet for each site, scratch the skin beneath each drop of allergen, no more than ⅛-inch deep.

10. Start the timer for the 20-minute reaction period.
11. After the reaction time has passed, cleanse each site with an alcohol prep pad. (Do not remove identifying labels until the practitioner has checked the patient.)
12. Assist the practitioner or examine and measure the sites.

FIGURE Procedure 42-1 Step 12 Physicians classify skin reactions as either negative (no greater than the reaction to the control) or positive. Positive reactions are rated on a scale of +1 to +4, depending on the size of the wheal.

13. Apply cold packs or an ice bag to sites as needed to relieve itching.
14. Properly dispose of used materials and instruments.
15. Clean and disinfect the area according to OSHA guidelines.
16. Remove the gloves and wash your hands.
17. Document the test results in the patient's chart, if required, and initial your entries (Refer to Progress Note).

PROCEDURE 42-2 Assisting with a Sigmoidoscopy

Procedure Goal: To assist the licensed practitioner during the examination of the rectum, anus, and sigmoid colon using a sigmoidoscope

OSHA Guidelines:

Materials: Sigmoidoscope, suction pump, lubricating jelly, drape, patient gown, and tissues

Method:

1. Wash your hands and assemble and position materials and equipment according to the licensed practitioner's preference.
2. Test the suction pump.
3. Identify the patient and introduce yourself.

4. Show the patient into the treatment room. Explain the procedure and discuss any concerns the patient may have.
5. Instruct the patient to empty the bladder, take off all clothing from the waist down, and put on the gown with the opening in the back.
6. Don exam gloves and assist the patient into the knee-chest or Sims' position. Immediately cover the patient with a drape.
7. Use warm water to bring the sigmoidoscope to slightly above body temperature; lubricate the tip.
RATIONALE: To ensure patient comfort.
8. Assist as needed, including handing the licensed practitioner the necessary instruments and equipment.
9. Monitor the patient's reactions during the procedure and relay any signs of pain to the practitioner.
10. Clean the anal area with tissues after the exam.
11. Properly dispose of used materials and disposable instruments.
12. Remove the gloves and wash your hands.
13. Help the patient gradually assume a comfortable position.
RATIONALE: The patient should sit up slowly so that he does not become faint.
14. Instruct the patient to dress.
15. Don clean gloves.
16. Sanitize reusable instruments and prepare them for disinfection and/or sterilization, as necessary.
17. Clean and disinfect the equipment and the room according to OSHA guidelines.
18. Remove the gloves and wash your hands.

PROCEDURE 42-3 Assisting with a Needle Biopsy

WORK // DOC

Procedure Goal: To assist the licensed practitioner with removing tissue from a patient's body so that it can be examined in a laboratory

OSHA Guidelines:

Materials: Patient chart/progress note, sterile drapes, tray or Mayo stand, antiseptic solution, cotton balls, local anesthetic, disposable sterile biopsy needle or disposable sterile syringe and needle, sterile sponges, specimen bottle with fixative solution, laboratory packaging, and sterile wound-dressing materials

Method:

1. Identify the patient and introduce yourself.
2. Instruct the patient as needed and discuss any concerns the patient may have.
3. Wash your hands and assemble the necessary materials.
4. Prepare the sterile field and instruments.
5. Don exam gloves.
6. Position and drape the patient.
7. Cleanse the biopsy site. Prepare the patient's skin.
RATIONALE: To reduce the possibility of infection.
8. Remove the gloves, wash your hands, and don clean exam gloves.
9. Assist the licensed practitioner as needed when she injects anesthetic.

10. Perform a surgical scrub and don sterile gloves if you will be handing the practitioner's sterile instruments.
11. Place the sample in the specimen container and label, complete the laboratory requisition form, and package the specimen for immediate laboratory transport.
RATIONALE: The specimen must be properly labeled and accompanied by a completed laboratory requisition form to ensure that the specimen is not lost and the appropriate tests are completed in the lab.
12. Apply a dressing to the patient's wound site.
13. Properly dispose of used supplies and instruments.
14. Clean and disinfect the room according to OSHA guidelines.
15. Remove the gloves and wash your hands.
16. Document as needed (Refer to Progress Note).

LEARNING OUTCOMES	KEY POINTS
42.1 Describe the medical specialties of allergy, cardiology, dermatology, endocrinology, gastroenterology, neurology, oncology, and orthopedics.	The medical specialties discussed in this chapter include allergy, which is diagnosing and treating allergies (inappropriate immune system responses); cardiology, which is the study and treatment of heart diseases and disorders; dermatology, or the diagnosis and treatment of skin diseases and disorders such as acne, eczema, and skin cancer; endocrinology, or the treatment of diseases and disorders of the endocrine system, which includes glands that regulate and coordinate the body systems; gastroenterology, or the diagnosis and treatment of disorders of the entire gastrointestinal (GI) tract from the mouth to the anus, as well as the liver and pancreas; neurology, or the diagnosis and treatment of diseases and disorders of the central nervous system (CNS) and associated systems; oncology, which is concerned with the detection and treatment of cancerous growths; and orthopedics, which focuses on disorders, injuries, and diseases of the muscular and skeletal systems.
42.2 Identify common diseases and disorders related to cardiology, dermatology, endocrinology, gastroenterology, neurology, oncology, and orthopedics.	Many common diseases and disorders are identified in the specialty practices. You should have an understanding of the implications of these diseases on the patient and the necessary treatments.
42.3 Relate the role of the medical assistant in examinations and procedures performed in the medical specialties of allergy, cardiology, dermatology, endocrinology, gastroenterology, neurology, oncology, and orthopedics.	Exams and diagnostic tests performed in allergy, cardiology, dermatology, endocrinology, gastroenterology, neurology, oncology, and orthopedics specialties are numerous. During most of these exams and tests, your role may include ensuring patient safety and comfort, educating the patient about the necessary preparation and the procedure, and assisting the licensed practitioner.

Recall Valarie Ramirez from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. How would you chart Valarie's chief complaint?
2. The physician thinks Valarie has a thyroid nodule that may be cancerous. Which two types of specialists might she need to visit?
3. Based on the results of the ultrasound, the physician wants to evaluate the thyroid nodule by performing a needle biopsy. What will be your responsibilities during this procedure?

EXAM PREPARATION QUESTIONS

- (LO 42.1) In which medical specialty practice would you *most* likely be working if you were assisting with a scratch test?
 - Dermatology
 - Cardiology
 - Oncology
 - Allergy
 - Endocrinology
- (LO 42.3) You just finished patient education for a patient who is to have a colonoscopy next week. At which of the following specialty practices do you *most* likely work?
 - Cardiology
 - Gastroenterology
 - Surgery
 - Urology
 - Oncology
- (LO 42.3) A patient has a growth on his arm and the licensed practitioner removes some of the tissue of the growth. He *most* likely had a
 - Needle aspiration
 - Wood's light examination
 - Needle biopsy
 - CABG
 - RAST test
- (LO 42.1) Which specialist would do a whole-body skin examination?
 - Dermatologist
 - Cardiologist
 - Oncologist
 - Allergist
 - Endocrinologist
- (LO 42.1) If a patient is suffering from Type 1 diabetes, what specialist would she *most* likely visit?
 - Dermatologist
 - Cardiologist
 - Oncologist
 - Allergist
 - Endocrinologist
- (LO 42.2) A patient has been diagnosed with the most dangerous type of skin cancer. What type of cancer does he have?
 - Basal cell
 - Melanoma
 - Squamous cell
 - Diabetic
 - Arthritic
- (LO 42.2) A patient has been diagnosed with Alzheimer's disease and will *most* likely see a specialist in
 - Neurology
 - Cardiology
 - Endocrinology
 - Oncology
 - Dermatology
- (LO 42.2) The type of medication used to treat cancer is
 - Electroencephalogram
 - Radiation
 - Retinoid
 - Contraceptives
 - Chemotherapy
- (LO 42.3) A patient has been instructed to sit up slowly after a sigmoidoscopy. What is the *most* likely reason?
 - To prevent bleeding
 - To maintain asepsis
 - To prevent the patient from getting faint
 - To check for a reaction
 - To ensure that the test is done accurately
- (LO 42.3) After a scratch test, you charted +4 pollen. What does this mean?
 - The test was negative
 - The test was mildly positive
 - The test was +4 on a scale of 1 to 10
 - The test was positive with a wheal of 10 mm
 - The test was positive with a wheal of 20 mm

Go to CONNECT to see an animation exercise about Coronary Artery Disease.

SOFT SKILLS SUCCESS

You are working in a cardiologist's office with a patient who had an episode of angina and a stent placed for a 90% blockage of the anterior interventricular branch of the left coronary artery, also known as a widowmaker. The patient did not have heart damage but needs to follow a more heart-smart lifestyle to prevent any cardiovascular problems. The licensed practitioner has asked that you spend time doing patient education with this patient before he leaves the office. When you enter the exam room to begin your patient education, the

patient makes the following comment: "I know why you are here, and I don't think you can do anything to help me." What should be your response?

Go to PRACTICE MEDICAL OFFICE and complete the module Clinical - Interactions.

Assisting with Eye and Ear Care

43

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Valarie Ramirez	8/4/19XX	Penicillin
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	829-78-462	Vital Signs: 128/84 98.7-92 -18 Ht. 5' 2" Wt. 135 lb.

Valarie Ramirez, a 33-year-old female, has been examined by the physician after complaining that something flew into her eye while she was riding her motorcycle yesterday. The physician has examined the eye and determined that there is

© McGraw-Hill Education

a small amount of debris in the eye. The physician has asked you to assist with eye irrigation.

Keep Valarie in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

McGraw-Hill Education **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 43, you will be able to:

- 43.1** Describe the medical assistant's role in eye exams and procedures performed in a medical office.
- 43.2** Discuss various eye disorders encountered in a medical office.
- 43.3** Identify ophthalmic exams performed in the licensed practitioner's office.
- 43.4** Summarize ophthalmologic procedures and treatments.
- 43.5** Describe the medical assistant's role in otology.
- 43.6** Describe disorders of the ear encountered in the medical office.
- 43.7** Recall various hearing and other diagnostic ear tests.
- 43.8** Summarize ear procedures and treatments.

KEY TERMS

- | | |
|-------------------------|----------------------------|
| accommodation | hyperopia |
| astigmatism | Ménière's disease |
| audiologist | myopia |
| audiometer | ophthalmoscope |
| cataract | otologist |
| cochlear implant | presbyopia |
| conductive hearing loss | refraction examination |
| conjunctivitis | sensorineural hearing loss |
| decibels | slit lamp |
| frequency | tinnitus |
| glaucoma | tonometer |

- I.C.8** Identify common pathology related to each body system including:
- (a) signs
 - (b) symptoms
 - (c) etiology
- I.C.9** Analyze pathology for each body system including:
- (a) diagnostic measures
 - (b) treatment modalities
- I.C.11** Identify the classifications of medications including:
- (a) indications for use
 - (b) desired effects
 - (c) side effects
 - (d) adverse reactions
- I.P.4** Verify the rules of medication administration:
- (a) right patient
 - (b) right medication
 - (c) right dose
 - (d) right route
 - (e) right time
 - (f) right documentation
- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.9** Assist provider with a patient exam
- I.A.2** Incorporate critical thinking skills when performing patient care
- I.A.3** Show awareness of a patient's concerns related to the procedure being performed
- V.P.4** Coach patients regarding:
- (a) office policies
 - (b) health maintenance
 - (c) disease prevention
 - (d) treatment plan
- V.A.3** Demonstrate respect for individual diversity including:
- (a) gender
 - (b) race
 - (c) religion
 - (d) age
 - (e) economic status
 - (f) appearance
- X.P.3** Document patient care accurately in the medical record

2. Anatomy and Physiology

- a. List all body systems, their structure and functions
- b. Describe common diseases, symptoms and etiologies as they apply to each system
- c. Identify diagnostic and treatment modalities as they relate to each body system

3. Medical Terminology

- c. Apply various medical terminology for each specialty

4. Medical Law and Ethics

- a. Follow documentation guidelines

9. Medical Office Clinical Procedures

- d. Assist provider with specialty examination including cardiac, respiratory, OB-GYN, neurological, gastroenterology procedures
- j. Make adaptations with patients with special needs

► Introduction

Think about how often you use your eyes and ears. You use your eyes to *read* the words on this page and to watch the rise and fall of a patient's chest while counting respirations.

Both your eyes and ears are needed when watching the dial on a sphygmomanometer while listening for the first Korotkoff sound while taking a blood pressure. These are daily activities for a medical assistant. Good eye and ear care is critical for you and for your patients. In this chapter, you will explore the

role of ophthalmology and otology in patient care, various eye and ear disorders, and exams and procedures related to the eye and ear, including vision and hearing tests.

► Ophthalmology LO 43.1

Ophthalmology is a branch of medicine specializing in the anatomy, function, and diseases of the eye. An ophthalmologist specializes in medical and surgical eye problems, treating the eyes and related tissues. The most common eye disorders that an ophthalmologist treats are visual defects, which are often correctable with eyeglasses or contact lenses. Ophthalmologists also treat eye injuries and remove foreign bodies from the eye. More serious disorders, such as cataracts and glaucoma, require medication or surgery. In an ophthalmologist's office, you may assist or perform some of the procedures that involve measuring various aspects and functions of the eye, such as visual acuity, color vision, and intraocular pressure. You also may perform some of these exams in a general practice office or an optometrist's office. Optometrists diagnose and treat visual defects only with glasses or contacts. Review eye anatomy and pathophysiology in the *Special Senses* chapter.

► Eye Diseases and Disorders LO 43.2

You may encounter a wide range of eye diseases and disorders in an ophthalmologist's or general practitioner's office. Some, such as a sty or conjunctivitis, do not greatly affect vision and may be treated by a general practitioner. Others affect the eye's internal workings and require a specialist's attention.

Disorders of External Eye Structures

Some disorders affect external eye structures, such as the eyelid and the eyelashes.

Blepharitis Blepharitis is a chronic inflammation of the eyelid's edges, more common in older individuals than in younger people. It can be caused by infection or by the same skin condition that causes dandruff. Symptoms include red, swollen eyelids with scaling or crusting of skin at the edges. The patient's eyes may be irritated and itchy. Proper eye care and hygiene often clear up the condition successfully. Antibiotic creams may be necessary in severe cases.

Ptosis Ptosis is a drooping of the upper eyelid in which the lid partially or completely covers the eye. It is caused by weakness of or damage to the muscle that raises the eyelid or by problems with the nerve that controls the muscle. Often no treatment is required, although surgery may be performed if the condition interferes with vision or if the patient is concerned about appearance.

Sty A sty (external hordeolum) is the result of an eyelash follicle infection. The microorganism most often responsible for the infection is *Staphylococcus aureus*. A red, painful swelling appears on the eye's edge and typically forms a white head of pus. The head bursts and drains before it heals

in about a week. Applying warm, moist compresses to the sty may help it drain sooner.

Disorders of Structures at the Front of the Eye

Another group of disorders affects structures at the front of the eye, which include the conjunctiva and the cornea.

Conjunctivitis **Conjunctivitis**, or pinkeye, is an inflammation of the conjunctiva caused by an allergy, irritant, or infection. It is a common disorder that is annoying but normally not serious.

Allergic conjunctivitis occurs when a person has an allergic reaction to pollen, makeup, or other substance. The symptoms are itchy, red eyes. The licensed practitioner may prescribe medication to relieve troublesome symptoms and suggest avoidance of the trigger whenever possible. Irritants such as dust, smoke, wind, pollutants, and excessive glare also may cause conjunctivitis.

Infectious conjunctivitis can be caused by either a bacterial or a viral infection. Both forms are easily spread and have symptoms including redness and a gritty feeling in the eye. Bacterial infections typically produce pus, which may form a crust on the eye during sleep. Viral infections usually produce a watery discharge. Although eye irrigation or saline drops may be used to soothe eyes affected by either type of infection, only bacterial infections are treated with antibiotic drops or ointment.

Because you may not know the cause of a patient's conjunctivitis (allergies, irritants, bacteria, viruses), take precautions to avoid spreading infection. As with any potentially infectious disease, use standard precautions in medical settings. Wear appropriate personal protective equipment when dealing with any patient who has conjunctivitis.

Corneal Ulcers and Abrasions Ulcers (lesions) on the cornea may be the result of injury, infection, or both. An injury such as an abrasion (scratch) on the cornea can become infected with bacteria, viruses, or fungi. The symptoms of a corneal ulcer include pain or discomfort and unclear vision. Treatment consists of antibiotic eyedrops or ointments and drops that temporarily paralyze the eye's ciliary muscles—those that control the shape of the lens—to help control pain. Patching the eye is no longer recommended because doing so creates a warm, moist environment that supports further growth of microorganisms.

Disorders Involving Internal Eye Structures

Another group of disorders affects structures inside the eye. Cataracts, for example, affect the lens, while glaucoma can damage several internal eye structures.

Cataracts **Cataracts** are cloudy or opaque areas in the normally clear lens of the eye. Cataracts develop gradually, blocking the passage of light through the eye. The result is a progressive loss of vision in one or both eyes. In severe cases, you can see the cloudy lens through the eye's pupil (Figure 43-1).

FIGURE 43-1 The lens of an eye with a cataract has a clouded appearance.

© Biophoto Associates/Science Source

Cataracts are more common in the elderly than in younger people, because the lens deteriorates with aging. Cataracts also can be caused by iritis, injury, ultraviolet radiation, or diabetes. Some cataracts are congenital. Treatment includes surgically removing the lens and using an artificial lens in its place. The artificial lens may be in the form of special eyeglasses, contact lenses, or an intraocular lens inserted at the time of cataract surgery.

Glaucoma **Glaucoma** is a condition in which fluid pressure builds up inside the eye. This pressure damages the eye's internal structures and gradually destroys vision. Glaucoma is the second leading cause of blindness in the United States and the first cause among African Americans. According to Prevent Blindness America, 2.3 million Americans over age 40 have glaucoma.

Capillaries in the ciliary body produce aqueous humor—a sticky, watery fluid that circulates between the lens and the cornea. In a patient with healthy eyes, this fluid drains out of this area through the angle formed by the iris and the cornea. The aqueous humor then diffuses into a vascular channel (Schlemm's canal) that encircles the cornea where it meets the sclera—the white of the eye (see the *Special Senses* chapter). The aqueous humor then returns to the systemic circulation (the circulation of the blood to body tissues). However, in a patient with glaucoma, the fluid drains out of the eye too slowly or fails to drain at all. The result is a buildup of intraocular pressure. Retinal nerve fibers are damaged and blood vessels are destroyed, leading to loss of vision and possible blindness.

Glaucoma is treated with medication that reduces pressure in the eye. Drops, pills, or both may be prescribed to reduce the production of aqueous humor. Sometimes, an iridotomy—a type of laser surgery procedure in which a small hole is created in the iris to allow excess fluid to drain—is performed. If the surgery is not effective, an iridectomy (partial removal of the iris) is done to create a larger opening in the iris.

Uveitis Uveitis is inflammation of the uveal track, which includes the iris, ciliary body, and choroid (refer to the *Special*

Senses chapter). The most common type of uveitis is known as anterior uveitis. The term *iritis* is used sometimes to describe anterior uveitis, even though anterior uveitis involves other parts of the eye. The cause is often unknown but may be associated with eye trauma, infection, and some autoimmune diseases. White blood cells from the inflamed area and protein that leaks from small blood vessels float in the aqueous humor. The symptoms of iritis are pain or discomfort in one or both eyes; pain may be worse in bright light. The eye is red and loss of vision may occur. Left untreated, uveitis can lead to other complications, such as glaucoma and cataracts. Anti-inflammatory drops or ointment are used to treat this condition.

Disorders of the Retina

Several serious disorders affect the retina—the internal layer of the back of the eye. These disorders include retinal detachment, diabetic retinopathy, and macular degeneration.

Retinal Detachment Retinal detachment occurs when the retina separates from the underlying choroid layer—the middle, vascular layer of the eye. When this separation occurs, vision is damaged.

Early symptoms of detachment include flashes of light or floating black shapes, both of which can occur as the hole in the retina forms. Patients occasionally describe their field of vision as being like a window shade that has been pulled down. Peripheral vision is lost as the retina detaches. Vision becomes progressively blurred as detachment continues.

A hole in the retina can be fixed with cryopexy—surgical fixation with cold. During the procedure, the physician places a freezing probe on the outside of the eye over the area of the retinal tear, freezing the area and creating a thin scar that seals the hole. If the retina has already detached, some vision can often be restored with surgical and laser treatments.

Diabetic Retinopathy Diabetic retinopathy is a complication of diabetes. People who have had diabetes for a long time or who do not keep their condition under control experience damage to small blood vessels that supply the retina. The vessels initially leak fluid, which distorts vision. As the disease progresses, fragile new blood vessels grow on the retina and bleed into the vitreous humor—the thick, jelly-like fluid that fills the posterior eye chamber. Scar tissue also may form on the retina. The result is loss of vision. The damage usually cannot be repaired, but the disorder can be controlled to prevent further loss of vision.

Macular Degeneration The macula is the area of the retina responsible for the central area of a person's visual field. For unknown reasons, the macula begins to deteriorate as some individuals age. Macular degeneration causes loss of vision in the center of an image; peripheral vision remains intact. Macular degeneration is the leading cause of blindness among the elderly in the United States. According to the National Eye Institute, 1.75 million Americans have age-related macular degeneration.

When an individual develops macular degeneration, the loss of sharp vision occurs very gradually and without pain.

One of the first signs is difficulty in reading. The loss of vision often appears as a dark spot in the center of the field of vision. If macular degeneration is detected early, laser surgery may restore some vision or prevent further loss.

Disorders Involving Eye Movement

Normally, both eyes move together when people look at objects. However, a deviation of one eye is called strabismus. In young children, misaligned or unbalanced eye muscles cause strabismus. This misalignment makes it appear as though the child is looking in two different directions. A condition called amblyopia may occur as the misaligned eye becomes “lazy.” The brain tends to ignore what the lazy eye sees; if the condition is not treated, vision will be affected in this eye. Treatment involves putting a patch over the fully working eye to force the child to use the other eye. Eyeglasses may be used along with the patch. In some cases, surgery on the eye muscle is required.

Strabismus in adults usually results from problems with the nerves connecting the brain and the eye muscles or with the muscles themselves. Conditions that can cause such problems include diabetes, high blood pressure, brain injury, muscular dystrophy, and inflammation of certain cerebral arteries. Treatment depends on the cause of the condition.

Refractive Disorders

Refraction refers to the way light from objects is focused through the eye to form an image on the retina. The normal eye focuses light exactly at the retina, producing a clear image (Figure 43-2). In some people, the eye focuses light either in front of or behind the retina, so the image is not clear. The problem may be the result of an abnormal shape of the eye or abnormal focusing of the light by the cornea and lens. The most common refractive disorders are nearsightedness, farsightedness, presbyopia, and astigmatism.

FIGURE 43-2 (a) Lens shape for distant vision and lens shape for near vision (accommodation). (b) Emmetropia, hyperopia, and myopia.

Myopia (Nearsightedness) Myopia is the condition in which images of distant objects come into focus in front of the retina and are blurred (Figure 43-2). This condition occurs if the eye is too long or if the cornea and lens bend light rays more than normally. Nearby objects are usually seen clearly, but objects far away are unclear.

Nearsightedness is corrected with eyeglasses or contact lenses that have inwardly curving (concave) lenses. The lenses correct the bending of light rays so that they focus on the retina. Surgical and laser techniques are also used to correct myopia by changing the shape of the cornea.

Hyperopia (Farsightedness) and Presbyopia

Hyperopia, or hypermetropia, causes images to come into focus behind the retina (Figure 43-2). The eyeball may be too short, or the cornea and lens may bend light rays less than normally. Faraway objects are usually seen clearly, but nearby objects are unclear. If the hyperopia is mild, young eyes can compensate for the problem by a process known as accommodation. The ciliary muscles contract during **accommodation**, thickening the lens and increasing its convexity. These changes allow the image to come into focus on the retina.

Patients with mild farsightedness may have no symptoms or may have blurred vision. They may have symptoms of eye-strain (an aching in the eye) because the ciliary muscles are overworked. Farsightedness is corrected with eyeglasses or contact lenses that have outwardly turning (convex) lenses. Aging usually causes the ciliary muscles to weaken, so a person may need stronger eyeglasses over time.

Presbyopia is a condition that most commonly affects people starting in their mid-40s. Older eyes tend to lose the ability to accommodate because the lens becomes more rigid. As a result, images come into focus behind the retina, as they do with farsightedness. Individuals find they must hold reading materials farther away to see them clearly. Corrective lenses are used to treat this condition.

Astigmatism Sometimes vision is distorted because the cornea is unevenly curved or the lens has an abnormal shape. This condition is called **astigmatism**. Astigmatism is treated with lenses that correct the unevenness of the cornea or laser vision correction surgery known as LASIK. After surgery, patients may still need to wear glasses to correct presbyopia.

► Ophthalmic Exams

LO 43.3

An ophthalmologist performs an eye exam by inspecting the interior of the patient's eyes, including the retina, optic nerve, and blood vessels. The instrument used for this exam is an **ophthalmoscope**, a handheld instrument with a light to view the inner eye structures. You will maintain and prepare this instrument for the licensed practitioner's use, as described in Procedure 43-1, at the end of this chapter.

During the eye exam, the practitioner tests the patient's visual fields. The visual field is the entire area visible to the eye when the patient looks at an object straight ahead. Visual fields are assessed by the confrontation method. The

practitioner stands or sits about 2 feet in front of the patient. The patient covers one eye, and the practitioner closes her own opposite eye. (This makes the visual fields of the two individuals roughly the same.) Then the practitioner moves a pencil or other object into the patient's horizontal or vertical visual field, asking the patient to say "Now" when the object comes into view. Defects in the field of vision are noted. The practitioner then tests the convergence of the eyes (or how the eyes come together) by bringing the handheld object to the patient's nose as the eyes focus on it.

The ophthalmologist also routinely tests for glaucoma with the aid of a **tonometer** (Figure 43-3). The tonometer measures intraocular pressure, shown by the eyeball's resistance to indentation by either direct pressure or pneumatic pressure. Your role is to explain the procedure to the patient, instill anesthetizing eye-drops into the patient's eyes when required, assist the patient into position, and hand the instruments to the licensed practitioner.

Another instrument the ophthalmologist may use during the exam is the **slit lamp** (Figure 43-4). This instrument consists of a magnifying lens combined with a light source. It is used to examine the eye's anterior structures, including the eyelids, iris, lens, and cornea. Patients rest their chin on the

(a)

(b)

FIGURE 43-3 Two types of tonometers are (a) the applanation tonometer, which actually touches the eyeball during assessment, and (b) the noncontact, or airpuff, tonometer, which directs a puff of air at the cornea.

© Ian Hooton/SPL/Getty Images

device's chin rest and stare straight ahead while the practitioner shines a narrow beam (slit) of light into the eye and looks at the eye through the instrument's lens. A special dye—fluorescein—may be used to help visualize foreign bodies or problems with the cornea.

The eye exam also may include a **refraction examination** to verify the need for corrective lenses. Normally, the lens and other parts of the eye work together to focus images on the retina. When errors of refraction exist, images are focused incorrectly, causing conditions such as farsightedness and nearsightedness.

A refraction examination is performed with a retinoscope or a phoropter, a device that contains many different lenses. The practitioner has the patient look through a succession of lens combinations to find out which one creates the clearest image (Figure 43-5).

Types of Vision Screening Tests

Screening tests are used to detect a number of common visual problems, including hyperopia, presbyopia, and myopia. Others test the ability to distinguish shades of gray or colors.

FIGURE 43-5 A phoropter helps the ophthalmologist assess errors of refraction.

© ERproductions Ltd/Getty Images RF

When you record the results of vision tests, be sure to document for which eye you are recording the results and note if the test was done with corrective lenses (glasses or contacts). If vision is tested with glasses or contacts, you will note this with the abbreviation (with correction). Details on how to perform various vision tests can be found in Procedure 43-2 at the end of this chapter.

Visual acuity screenings are procedures commonly performed by medical assistants either before or after the licensed practitioner's exam. These tests screen for distance vision, near vision, and color vision.

Distance Vision The Snellen chart is the most common screening tool for distance vision. You may be familiar with the Snellen letter chart used by many eye professionals. Snellen number charts and “tumbling E” charts are also available. (See Figure Procedure 43-2 Step 2 a and b.) These charts and similar charts that use symbols instead of numbers or letters are often used to test the visual acuity of children.

Near Vision To test for near vision, a Jaeger chart or similar chart is used (Figure Procedure 43-2 Step 21 b and c). These handheld cards contain letters, numbers, or paragraphs in various print sizes. They may be held and read at a normal reading distance (Figure Procedure 43-2 Step 21 a) or mounted in a frame and read through optical lenses. As you may recall, presbyopia is an age-related loss of lens elasticity that affects a person's near vision. The combination of myopia and presbyopia is the reason many people require bifocal lenses as they age.

Color Vision Color vision is commonly tested using a system of colored dots. The two most frequently used testing systems are the Ishihara Color Test (Figure 43-6) and the Richmond pseudoisochromatic color test. Both contain letters, numbers, or symbols made up of colored dots that appear among dots of other colors. The patient is asked to identify what he sees. A patient who is color-blind will not be able to see the items. Color blindness may be inherited; it occurs more commonly in males. Changes in one's ability to see colors, however, may indicate a disease of the retina or optic nerve.

FIGURE 43-6 The Ishihara Color Test, one of the most common color vision tests, uses a system of colored dots to test for color blindness.

© McGraw-Hill Education

Contrast Sensitivity To test for the ability to distinguish shades of gray (contrast sensitivity), Evans Letter Contrast Test (ELCT) and the CSV-1000E contrast sensitivity test are widely used. Some systems provide contrast variations in a projected image (Figure 43-7). These tests can detect cataracts or problems in the retina even before the sharpness of the patient's vision is impaired.

Patients with Special Needs Certain patients may need special attention when having vision tests. For example,

children may be anxious, uncooperative, or unable to follow directions. A patient with Alzheimer's disease or another type of dementia also may require special attention during a vision test. Before the test, encourage a family member to stay with the patient so that she is more comfortable. During the test, use simple language to explain the procedure and demonstrate whenever possible. Proceed through the exam slowly, one step at a time. Because the patient's memory and language skills may be impaired, you may need to repeat directions many times and help her to name particular objects. If she appears to have trouble with one part of the exam, proceed to another part and return later to the part that was difficult for her.

► Ophthalmologic Procedures and Treatments

LO 43.4

The eye is an extremely delicate organ. Even what seems to be a minor injury or infection can have lasting consequences. You must use the greatest caution as well as proper technique—including sterile technique—when treating a patient's eyes. You also should provide patients with information on how to routinely care for their eyes. See the *Educating the Patient* feature for specific guidelines to follow when presenting eye care information.

Administering Medications to the Eye

Licensed practitioners commonly administer eye medications or perform eye irrigations to assist patients in eye tests, reduce pressure in the eyes, relieve eye pain, and treat eye infections and inflammation. Your responsibility as a medical assistant may include dispensing medications and explaining their use. Some medications are used to diagnose conditions; others are used to treat conditions. Only medications for ophthalmic use should be used in the eye. If you administer eye medications as part of your job, avoid touching a dropper or ointment tube tip to the eye. Doing so can injure the eye, cause infection, and contaminate the medication. Teach patients how to check medication labels carefully before administering them at home. For example, optic medications for eye use could easily be confused for otic medications for the ear. Medications other than optic medications may be too concentrated or may contain substances that will injure sensitive eye tissue.

Although most eye medications are administered for local effect, some are absorbed systemically (affecting the whole body). To prevent systemic absorption, the practitioner may request that you apply pressure with one finger just below the inner corner of each eye after instilling medications.

EDUCATING THE PATIENT

Preventive Eye Care Tips

You can help patients take care of their eyes and protect their vision by providing them with the following guidelines. Go over each item slowly and carefully. Ask whether the patient has questions before moving on to the next item. Answer all questions and make sure the patient understands the answers.

1. Get regular health checkups. Patients may not appreciate the connection between their general health and their eyes. Point out that high blood pressure and diabetes can cause eye problems.
2. Get regular eye examinations. Most people need eye examinations every 1 to 2 years. Patients with diabetes should see their eye care specialists more frequently.
3. Be alert for eye disease warning signs. Tell patients to call their eye care specialist immediately if they experience any of these signs:
 - Eye pain
 - Loss of vision
 - Double or blurred vision
 - Headache with blurred vision
 - Redness of the eye or eyelid
 - A gritty or sticky feeling around the eye
 - Excessive tearing
 - Difficulty seeing in the dark
 - Flashes of light
 - Halos around lights
 - Sensitivity to light
 - Loss of color perception
4. Wear sunglasses with ultraviolet protection to shield the eyes from bright sunlight, even in the winter. Recommend that patients ask to have ultraviolet protection added when purchasing new distance prescription glasses. Explain to patients that the cornea can get sunburned, which can be painful and damaging. Also tell patients that excessive exposure to the sun is a contributing factor in the development of cataracts and malignant melanoma of the eye—a dangerous type of skin cancer that may spread through the bloodstream or lymphatic system.
5. Wear protective eye equipment to prevent eye injury. Indicate to patients that they should wear protective eyewear every time they participate in sports, work with chemicals, or encounter a situation in which they may be exposed to flying debris.
6. Use nonprescription eye medications properly. Show patients how to use eyedrops, emphasizing that the tip of the dropper should never touch the eye. Explain that medications should be used only as indicated on the label and discarded after the condition has cleared up.
7. Never share eye makeup, because bacterial infections can be passed via the applicators. To minimize contamination of the applicators, patients should take care of the applicators by storing them in a clean container and changing the applicator often. Patients should never place applicators on a dirty countertop.

Continue applying pressure for 2 to 3 minutes, as directed. Procedure 43-3, at the end of this chapter, provides information on administering eye medications.

Eye Irrigation

When foreign materials such as dust, sand, or chemicals enter the eye, they must be flushed out. Flushing—irrigation—should be done, whenever possible, with a sterile solution especially formulated for this purpose. Someone's eye also may need to be irrigated to relieve discomfort from irritating substances such as smog, pollen, chemicals, or chlorinated water. Procedure 43-4, at the end of this chapter, provides details about irrigating an eye. See the *Infection Control Fundamentals* chapter for more information on using an eyewash station.

▶ Otolology

LO 43.5

An **otologist** treats diseases and disorders of the ears. Procedures common to this specialty are sometimes performed by other physicians as well, especially general practitioners, internists, and allergists. In your role as

a medical assistant, you also may assist with or perform auditory screening, administer ear medications, perform ear irrigations, and help with diagnostic tests such as tympanometry. Otolology specialists whose practices include problems affecting the nose and throat are called otorhinolaryngologists.

▶ Ear Diseases and Disorders

LO 43.6

When assisting licensed practitioners in administering various tests, treatments, and procedures, you may encounter a wide range of ear disease and disorder. Some—such as cerumen impaction and otitis externa—do not have lasting effects on hearing and may be treated by a general practitioner. Others affect the ear's middle or inner parts and may require a specialist's attention. Figure 43-8 shows the major parts of the ear. For more detailed information, refer to the *Special Senses* chapter.

Common Disorders of the Outer Ear

Several disorders affect the ear's external parts. These include cerumen impaction, otitis externa, and pruritus.

FIGURE 43-8 The major parts of the ear.

Cerumen Impaction A condition called cerumen impaction occurs when the ear canal becomes blocked by a buildup of cerumen (earwax). The wax can be softened with eardrops, and irrigation can be performed to remove the wax. Refer to Procedure 43-7, at the end of this chapter, for more information about ear irrigation.

Otitis Externa Otitis externa is an infection of the outer ear, usually caused by bacteria or fungi. Also known as swimmer's ear, fungal infections are common in swimmers due to persistent moisture in the ear canal. This infection is treated with a combination of antibiotic or antifungal eardrops and an anti-inflammatory medication.

Pruritus A common problem in the elderly is pruritus—or itching—of the ear canal. Because the sebaceous glands produce less wax with aging, the ear becomes dry and itchy. Dryness can be overcome by a regular routine of lubricating the ear canal with a few drops of mineral oil.

Common Disorders of the Middle Ear

Middle ear disorders involve the eardrum and the chamber behind it. They include otitis media, mastoiditis, otosclerosis, and ruptured eardrum.

Otitis Media Otitis media is an inflammation of the middle ear characterized by fluid buildup, most commonly referred to as an ear infection. For detailed information on otitis media, see the *Points on Practice* feature Otitis Media: The Common Ear Infection.

Mastoiditis The mastoid bone is located just behind the ear. It is connected to the middle ear by air cells, or sinuses, in the bone. Sometimes, if left untreated, an infection in the middle ear can spread to the mastoid bone through these air cells. Although mastoiditis is fairly rare, it may be serious because the mastoid air cells are close to the organs of hearing, important nerves, the covering of the brain, and the jugular vein. Severe cases of mastoiditis may require removal of the affected bone.

Otosclerosis Otosclerosis occurs when bone tissue grows abnormally around the stapes, or stirrup (the innermost of the three tiny bones that connect the eardrum and the inner ear). This overgrowth of tissue prevents the stapes from transmitting sound vibrations to the inner ear. The result is hearing loss in one or both ears. The condition is often hereditary.

Symptoms of otosclerosis include gradual loss of hearing and **tinnitus**—ringing in the ears. Surgery to replace

POINTS ON PRACTICE

Otitis Media: The Common Ear Infection

Otitis media, commonly referred to as an ear infection, affects almost all children by age 6. This inflammation of the middle ear accounts for 22 million doctor visits each year—second only to routine well-child health exams.

Ear infections typically start when fluid becomes trapped in the middle ear. The lining of the middle ear and eustachian tube contains fluid similar to the mucus within the nasal passages. The normal flow of this fluid from the ear into the back of the nose where it joins the pharynx helps keep the middle ear and eustachian tube free of bacteria. When a child gets a cold or flu, the lining of the eustachian tube and middle ear can become inflamed and can trap the fluid, which becomes infected.

There are four distinct types of otitis media. One or both ears may be affected.

1. Acute otitis media typically is a bacterial infection of the middle ear that comes on suddenly. This type is common in children and typically follows an upper respiratory tract infection. The symptoms include pain, a feeling of fullness in the ear, some loss of hearing, and possibly fever. In severe cases, the eardrum may rupture because of the fluid pressure. Acute infections are not usually treated with oral antibiotics at first. Most infections will resolve on their own without treatment, so physicians usually wait 48–72 hours before prescribing antibiotic treatment for a patient with acute otitis media.
2. Recurrent otitis media is diagnosed when a child contracts acute otitis media repeatedly, perhaps once or twice every month.
3. Otitis media with effusion, also known as OME, involves an accumulation of fluid in the middle ear. Children with OME do not exhibit any symptoms, and they may not experience any discomfort.
4. Chronic otitis media is diagnosed when fluid is present in the ear and fails to clear up after 3 months or more. Infection may or may not be present. Without treatment, the undrained fluid thickens, possibly resulting in changes in the shape of the eardrum, erosion of the ossicles (tiny bones of hearing), and mastoiditis. Chronic otitis media left untreated for a sufficient amount of time can result in facial paralysis, brain infections, and balance problems. These changes may cause temporary or permanent hearing loss if not treated. Antibiotics and reconstructive surgery may be used to treat this condition.

If a child suffers from recurrent or chronic otitis media, myringotomy—surgical incision of the eardrum with insertion of tubes—may be recommended to keep the fluid draining continuously. This procedure usually removes enough fluid to clear up the infection. Depending on the type of tube, it falls out on its own within 3 to 18 months of insertion. See Figure 43-9.

FIGURE 43-9 A pressure-equalizing tube is inserted in the eardrum to help keep fluid from building up behind the eardrum.

Ear infections may be difficult to identify, especially in a young child who cannot talk. The following symptoms are indications of a possible ear infection, particularly if more than one is present:

- Tugging or rubbing of the ear
- Fever ranging from 100°F to 104°F
- Difficulty balancing
- Excessive crankiness
- Difficulty hearing or speaking
- An unwillingness to lie down (the pain may become more severe in a reclining position because of increased pressure against the eardrum)

Preventing ear infections is the best course of action. Several measures can be taken to reduce the likelihood of ear infections, including

- Preventing colds by teaching children to wash their hands often and not share cups and other eating utensils.
- Limiting a child's exposure to secondhand smoke.
- Breastfeeding for at least 6 months.
- Bottle feeding in an upright position—*never* put a baby to bed with a bottle.
- Keeping immunizations such as flu shots and pneumococcal vaccines up to date.

the stapes—ossicular replacement prosthesis surgery—can restore or improve hearing in almost 90% of patients with otosclerosis. Alternatively, a hearing aid may improve hearing for some patients.

Ruptured Eardrum The eardrum may become ruptured in several ways: by a sharp object, an explosion, a blow to the ear, or a severe middle ear infection. Sometimes the eardrum is ruptured by a sudden change in air pressure, as might occur when flying in an airplane or diving. Symptoms include pain, partial hearing loss, and a slight discharge or bleeding. The symptoms typically last only a few hours. A ruptured eardrum usually heals on its own in 1 to 2 weeks, but the licensed practitioner may use a temporary patch to help close the defect.

Common Disorders of the Inner Ear

Disorders of the inner ear, or labyrinth, affect the cochlea and the semicircular canals. They include labyrinthitis, Ménière's disease, presbycusis, and tinnitus.

Labyrinthitis Labyrinthitis is an infection of the labyrinth, most commonly caused by a virus. Because the labyrinth includes the semicircular canals, which are involved in balance, this infection causes symptoms of dizziness or vertigo. The room may appear to spin and any movement exacerbates (worsens) the sensation, sometimes to the point of nausea and vomiting. Although disturbing, labyrinthitis disappears on its own within 1 to 3 weeks. The patient may need to rest in bed for a few days, and medication can be given for symptoms.

Ménière's Disease Ménière's disease is caused by increased fluid in the labyrinth. The pressure of the fluid disturbs the sense of balance and may even rupture the labyrinth wall or damage the cochlea with its hearing receptors. One or both ears may be affected. Symptoms of this disorder include vertigo, nausea, vomiting, distorted hearing, and tinnitus. Some people may suffer hearing loss ranging from mild to severe. Medications may be used to combat vertigo, nausea, and vomiting. Other treatments that help some people include using diuretics and following a low-sodium diet.

Presbycusis Presbycusis is a type of sensorineural hearing loss. It is the most common form of hearing loss in older adults, affecting about 25% of people by the age of 60 or 70. Men are affected more often than women. Hearing loss can be treated effectively, however, with a hearing aid.

Tinnitus Tinnitus is more commonly called a ringing in the ears. This “ringing” can take several forms, including a buzzing, whistling, or hissing sound. The most common causes of tinnitus are damage to the hearing receptors from noise or toxins, age-related changes in the ear's organs, and long-term use of nonsteroidal anti-inflammatory drugs (NSAIDs) such as aspirin and ibuprofen. Tinnitus can affect people at any age but is more common as people get older. If tinnitus becomes chronic, the patient may find relief by listening to quiet, soothing music or other distracting sounds or by using a device similar to a hearing aid that masks the noise with more pleasant sounds.

Hearing Loss

Hearing loss is actually a symptom of a disease, not a disease in itself. Contrary to what most people believe, hearing loss is not a normal part of the aging process and should always be evaluated for proper treatment. There are two types of hearing loss: conductive and sensorineural. The two types differ in the point at which the hearing process is interrupted.

A **conductive hearing loss** is caused by an interruption in the transmission of sound waves to the inner ear. Conditions that can cause conductive hearing loss include obstruction of the ear canal (as with cerumen impaction or a tumor), infection of the middle ear, and otosclerosis or reduced movement of the ossicles.

A **sensorineural hearing loss** occurs when there is damage to the inner ear, to the nerve that leads from the ear to the brain, or to the brain itself. In this kind of loss, sound waves reach the inner ear, but the brain does not perceive them as sound. This type of hearing loss can be hereditary, can be caused by repeated exposure to loud noises or viral infections, or can occur as a side effect of medications such as NSAIDs and some antibiotics. Tinnitus suggests damage to the auditory nerve.

Sensorineural hearing loss can be differentiated from conductive hearing loss by hearing tests. It is also possible for both types of hearing loss to occur together.

Noise Pollution Prolonged exposure to loud noises is a common cause of hearing loss because of damage to the sensitive cells in the cochlea. People who work around noisy equipment—such as construction workers, aircraft personnel, and machine operators—are likely to suffer from this type of hearing loss unless they protect their ears (Figure 43-10). Repeatedly listening to loud music from a personal stereo or car radio set at too high a volume also can damage the ears.

Working with Patients with a Hearing Impairment

You may come in contact with patients of all ages who have hearing impairments. Many patients wear hearing aids to amplify normal speech. Some patients, however, may not

FIGURE 43-10 Loud noises, such as those produced by power tools, can damage hearing unless appropriate ear protectors are worn.

© Wave Royalty Free/age fotostock RF

admit they have a problem—out of fear, vanity, or misinformation. It is estimated that one-third of patients between the ages of 65 and 74 and one-half of those between the ages of 75 and 79 suffer from some loss of hearing.

To improve communication with a patient whose hearing is impaired, you can do the following:

- Speak at a reasonable volume. Do not shout. Shouting can actually make your words harder to understand. A hearing aid filters out loud sounds, so the patient may not hear everything you say if you shout.
- Speak in clear, low-pitched tones. Elderly patients may lose the ability to hear high-pitched sounds.
- Avoid speaking directly into the patient's ear. Stand 3 to 6 feet away and face the patient so that she can see your lip movements and facial expressions. Avoid covering your mouth with your hands. Speak at a normal rate.
- Avoid overemphasizing your lip movements, which makes lip reading difficult.
- Avoid hand gestures unless they are appropriate.
- If the patient does not understand what you say, restate the message in short, simple sentences. Have the patient repeat the message to verify that your words were understood.
- Treat patients who have a hearing impairment with patience and respect.

► Hearing and Other Diagnostic Ear Tests

LO 43.7

Various tests are performed to find out whether a person hears normally. If the tests reveal a problem, follow-up tests are conducted to determine the cause of the problem. You may assist with the testing or educate the patient about caring for her ears.

Hearing Tests

As part of a general examination, licensed practitioners may perform simple hearing tests to determine whether a patient's stated hearing loss is conductive or sensorineural. The most common of these are the Weber test and the Rinne test. Both involve the use of tuning forks (see Figure 43-11).

In the Weber test, the licensed practitioner strikes a tuning fork against a hard surface to produce a sound and then places the tuning fork in the middle of the patient's head (Figure 43-12a). She then asks the patient whether the sound is coming from the right or the left, or both. In conductive hearing loss, the sound will be heard best through the ear with hearing loss. In sensorineural hearing loss, the sound travels toward the ear without hearing loss.

FIGURE 43-11 A tuning fork is used to perform simple hearing tests.

© Spike Mafford/Getty Images RF

To perform the Rinne test, the practitioner measures the amount of time the patient can hear the sound from a tuning fork placed near the mastoid bone (see Figure 43-12b). This measures sound conducted through the bone. She then measures the amount of time the patient can hear the sound when the tuning fork is placed near the ear canal to measure sound conducted through the air (see Figure 43-12c). The two times are then compared. A normal ear will hear the air-conducted sound twice as long as the bone-conducted sound. In a patient with conductive hearing loss, the bone-conducted sound will be at least as long as the air-conducted sound. In a patient with sensorineural hearing loss, the air-conducted sound will last slightly longer than the bone-conducted sound, but not twice as long.

If you have the necessary training, you may help perform a test that uses an audiometer. An **audiometer** is an electronic device that measures hearing acuity by producing sounds in specific frequencies and intensities. A **frequency** is the number of complete fluctuations—waves—of energy that pass a specific point in 1 second (Figure 43-13). Frequency is best described as the pitch of sound. High frequency is high-pitched and low frequency is low-pitched. The audiometer allows a licensed practitioner to test a person's hearing and to determine the nature and extent of hearing loss.

Many types of audiometers are available. Some machines automatically generate the various tones at different **decibels** (units for measuring the relative intensity—loudness—of sounds on a scale from 0 to 130) and print out the patient's responses. Others must be manually adjusted and the results charted by hand. During the test, the patient wears a headset to hear the sounds produced by the audiometer. Depending on the unit, the patient indicates hearing a sound by raising

FIGURE 43-12 (a) During the Weber hearing test, the tuning fork is placed on the patient's forehead. (b) Place the tuning fork on the mastoid bone during the Rinne hearing test. (c) Place the tuning fork near the ear during the Rinne hearing test. Compare how long the patient can hear the sound during each step.

© McGraw-Hill Education. Jill Braaten, photographer

a finger or pushing a button. In the former case, the person administering the test records the response. In the latter case, the response may be recorded automatically or by the test giver. Procedure 43-5, at the end of this chapter, provides additional information about measuring auditory acuity.

Adults and children who can understand directions and respond appropriately can be screened in this manner. If you work in a pediatrician's office, you also may help to check an infant's response to sounds. These tests require special techniques, as infants cannot understand directions. The general steps involved in performing hearing tests on infants are outlined in the *Assisting in Pediatrics* chapter.

- Cerumen impaction
- Middle ear fluid
- Middle ear tumor
- Ossicular detachment
- Tympanic membrane perforation
- Tympanic membrane scars

To perform the test, a small, soft-rubber cuff is placed over the external ear canal, producing an airtight seal. The tympanometer then automatically measures air pressure against the tympanic membrane and prints a graph of the results. Let patients know that they will hear sounds during the test that may seem loud, but they need to remain as still as possible.

Tympanometry

A diagnostic test called tympanometry measures the eardrum's ability to move. This is an indication of the amount of pressure in the middle ear. Tympanometry is used to detect the following diseases and abnormalities of the middle ear or ear canal.

▶ Ear Treatments and Procedures LO 43.8

Licensed practitioners use various approaches, devices, and techniques with each type of ear problem to improve patients' hearing and maintain or improve their ear health. As a medical assistant, you can provide patients with information on preventive ear care techniques, as described in the *Educating the Patient* feature Preventive Ear Care Tips.

FIGURE 43-13 Sound frequency is determined by the number of waves per second that pass a specified point.

You also may administer ear medications, perform ear irrigations, and assist the physician in earwax removal.

Administering Medications to the Ear

Licensed practitioners often administer eardrops or perform ear irrigations to treat patients' ear infections or inflammation, relieve ear pain, or loosen earwax. Like eye medications, eardrops are used primarily for their local effects. They are not usually absorbed systemically, nor do they cause systemic effects. It is important that you warm the eardrops slightly before administration to avoid making the patient dizzy. Holding them in your hand for a minute or two will usually warm them enough. Procedure 43-6, at the end of this chapter, provides instructions for this procedure.

Earwax and Foreign Body Removal

Cerumen, or earwax, may build up in the ear canal, causing a full feeling in the ear, ear pain, partial hearing loss, and tinnitus. Cerumen normally protects the ear, but if a person produces too much, it can harden and block the ear canal. Also, cleaning your ear with cotton-tipped swabs can push the cerumen down into the ear canal. There are several treatments for removing earwax. In some cases, if the wax is close enough to reach, the licensed practitioner may be able to remove the wax with an ear curette, a small instrument with a scoop or loop on one end. Home remedies include over-the-counter wax softening drops, mineral oil, and glycerin. These may work

if the impaction is not too severe. But if the wax is extremely hard or is stuck to the ear canal, irrigation may be the best treatment.

Ear Irrigation Irrigating the ear may relieve inflammation or irritation of the ear canal and help loosen and remove impacted earwax or a foreign body. This procedure is performed in the licensed practitioner's office. Irrigation is contraindicated in (inadvisable for) patients who

- Currently have or have had a ruptured eardrum.
- Have pressure equalizing tubes in their eardrum.
- Have an ear infection.
- Have had ear surgery, including mastoidectomy.

Always ask the patient about ear surgeries and other conditions before beginning the irrigation and make sure the irrigation solution is at body temperature before starting. This helps reduce the possibility of the patient becoming dizzy during the procedure. Procedure 43-7, at the end of this chapter, provides instructions for ear irrigation.

EDUCATING THE PATIENT

Preventive Ear Care Tips

You can help patients protect their ears and their hearing by providing them with the following guidelines. As with any patient education, go over items slowly, ask patients whether they have questions before moving on, and answer all questions completely.

1. Get routine hearing exams. Screening for hearing problems is often part of a comprehensive physical exam. Encourage patients who have not had their hearing screened or who suspect they have hearing problems to arrange for testing by their licensed practitioner. Older patients, who may not admit they have a problem, may need special encouragement.
2. Avoid injury when cleaning the ears. Instruct patients in proper ear care. Point out that they should not put objects in the ear that might injure the eardrum or ear canal, which includes vigorous probing with cotton-tipped swabs.
3. Avoid injury from nonprescription ear care products. Tell patients to check with a licensed practitioner before using nonprescription products for softening earwax.
4. Use proper ear protection. Urge patients to wear ear protectors around loud work equipment and to avoid listening to loud music. It is especially important to keep

the volume at a reasonable level when listening through earphones and through earbuds that fit directly into the external auditory canal.

5. Use all medications properly. Show patients how to use eardrops; emphasize that they must follow instructions precisely. Explain to patients that following instructions applies to all medications because many, including NSAIDs and some antibiotics, can cause hearing loss if used improperly.
6. Be alert for warning signs. Tell patients to call their licensed practitioner immediately if they experience any of these signs of ear problems:
 - Ear pain
 - Stuffiness
 - Discharge from the ear
 - Vertigo (dizziness)

Also have patients notify the licensed practitioner if they have any of these signs of hearing problems:

- Tinnitus (ringing)
- Hearing others' speech as mumbled sounds
- Speaking in a very loud voice without being aware of it

Microscopic Earwax and Foreign Body Removal

Occasionally, irrigation does not work to remove a cerumen impaction. With the help of a microscope, an otologist can use suction or an instrument to remove the wax. Foreign bodies in the ear also are removed with the aid of a microscope. During the procedure, the licensed practitioner looks through the microscope into the patient's ear canal. This gives her a better view of the ear, allowing her to get deeper into the ear canal without damaging the delicate structures within the ear. The patient must remain extremely still during this procedure. Your role as a medical assistant is to help keep the patient at ease and comfortable and to make sure the practitioner has the necessary instruments.

Hearing Aids

Hearing aids may be worn inside or outside the ear. If worn outside, they may be located behind the ear, mounted on eyeglasses, or worn on the body (Figure 43-14). Hearing aids consist of the following parts:

- A tiny microphone to pick up sounds
- An amplifier to increase the volume of sounds
- A tiny speaker to transmit sounds to the ear

You may need to teach patients how to obtain a hearing aid. You also can pass along tips to help them take proper care of their hearing aids and to troubleshoot problems.

Obtaining a Hearing Aid A patient with signs of hearing loss should be referred to an otologist, a medical doctor specializing in the health of the ear, or an **audiologist**, a specialist who focuses on evaluating and correcting hearing problems. Audiologists are not medical doctors and do not treat diseases of the ear. Instead, they evaluate the patient's hearing, fit hearing aids, give instruction in the use of hearing aids, and provide service for hearing aids if necessary. It is important for hearing aids to fit properly. If they do not, sounds may not be transmitted well into the ear.

Care and Use of Hearing Aids Hearing aids run on batteries that typically last about 2 weeks. So the patient must keep a fresh supply of batteries on hand. The hearing aid itself must be routinely cleaned or the microphone, switches, or dials may not work properly. Moisture can damage the aid, so it must not get wet. Hair sprays can clog hearing aid openings or interfere with the operation of moving parts. For these reasons, spray should be applied before a hearing aid is inserted. Cerumen often builds up behind hearing aids that are worn in the ear, reducing sound transmission. If buildup does occur, the cerumen plug should be removed by ear irrigation.

Other Devices and Strategies

People whose hearing cannot be substantially improved by hearing aids may need to use other devices or strategies to

FIGURE 43-14 A hearing aid can be so small that it is inserted inside the ear canal.

overcome the problem. These devices include appliances that light up as well as ring—such as telephones, doorbells, smoke detectors, alarm clocks, and burglar alarms. Patients can purchase amplifiers for the telephone, television, and radio. Many closed-captioned television programs are also available. To benefit from closed captioning, the patient must have a television with a decoder that translates the captioning and displays the captions on the screen.

Cochlear Implants

A person who is profoundly deaf and cannot benefit from using a hearing aid may be a candidate for a **cochlear implant**, an electronic device that stimulates the auditory nerve. A cochlear implant has an external and an internal component. The external portion sits just behind the ear and the internal portion has an array of electrodes implanted directly into the cochlea. Cochlear implants do not amplify sound like a hearing aid but send signals through the auditory nerve to the brain. This gives patients the ability to detect warning signals such as smoke alarms and recognize speech patterns so that they can be better understood. Hearing with a cochlear implant is not the same as normal hearing; patients have to learn to recognize sounds. Adults with cochlear implants can often learn to understand speech without using visual cues such as lip reading. Children can learn to speak with extensive speech therapy. More than 42,000 adults and 28,000 children in the United States have cochlear implants.

PROCEDURE 43-1 Preparing the Ophthalmoscope for Use

Procedure Goal: To ensure that the ophthalmoscope is ready for use during an eye exam

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Ophthalmoscope, lens, spare bulb, spare battery

Method:

1. Wash your hands.
2. Take the ophthalmoscope out of its battery charger. In a darkened room, turn on the ophthalmoscope light.
3. Shine the large beam of white light on the back of your hand to check that the instrument's tiny lightbulb is providing strong enough light.
4. Replace the bulb or battery if necessary. (The battery is located in the ophthalmoscope's handle.)
5. Make sure the instrument's lens is screwed into the handle. If it is not, attach the lens.

FIGURE Procedure 43-1 Step 3 Shine the ophthalmoscope light on your hand to check the strength of the beam.

PROCEDURE 43-2 Performing Vision Screening Tests

WORK // DOC

Procedure Goal: To screen a patient's ability to see distant or close objects, to determine contrast sensitivity, or to detect color blindness

OSHA Guidelines:

Materials: Eye occluder or card to block vision in one eye; alcohol; gauze squares; appropriate vision charts to test for distance vision, near vision, and color blindness; patient chart/progress note

Method:

Distance Vision

1. Wash your hands, clean the occluder with a gauze square dampened in alcohol, identify the patient, introduce yourself, and explain the procedure.
2. Mount one of the following eye charts at eye level: Snellen letter or similar chart (for patients who can read); Snellen tumbling E, Landolt C, pictorial, or similar chart (for patients who cannot read).

If using the Snellen letter chart, verify that the patient knows the letters of the alphabet. With children or nonreading adults, use demonstration cards to verify that they can identify the pictures or direction of the letters.

RATIONALE: If the patient does not understand the instructions, the results will not be accurate.

(a)

FIGURE Procedure 43-2 Step 2 (a) The Snellen letter chart is used to test the vision of people who can read.

© McGraw-Hill Education/Rick Brady, photographer

(b)

FIGURE Procedure 43-2 Step 2 (b) The Snellen “tumbling E” chart is used to test the vision of children and nonreading adults.

Reprinted with permission of Richmond Products, Inc.

3. Make a mark on the floor 20 feet away from the chart.
4. Have the patient stand with his or her heels at the 20-foot mark, or sit with the back of the chair at the mark.
5. Instruct the patient to keep both eyes open and not to squint or lean forward during the test.

RATIONALE: *Closing one eye, squinting, or leaning will lead to inaccurate results.*

6. Test both eyes first, then the right eye, and then the left eye. (Different offices may test in a different order. Follow your office policy.)

RATIONALE: *Following a specific testing order based on office policy leads to consistency in the results of all medical records.*

7. Have the patient read the lines on the chart (or identify the picture/direction), beginning with the 20-foot line. If the patient cannot read this line, begin with the smallest line the patient can read. (Some offices use a pointer to select one symbol at a time in random order to prevent patients from memorizing the order.)
8. Note the smallest line the patient can read or identify with no more than two errors. (Some offices only allow one error per line. Follow office policy when performing this test.)
9. Record the results as a fraction (for example, Both Eyes 20/40–1 if the patient misses one letter on a line or Both Eyes 20/40 –2 if the patient misses two letters on a line).
10. Show the patient how to cover the left eye with the occluder or card. Again, instruct the patient to keep both eyes open and not to squint or lean forward during the test.

11. Have the patient read the lines on the chart.
12. Record the results of the right eye (for example, Right Eye 20/30).
13. Have the patient cover the right eye and read the lines on the chart.
14. Record the results of the left eye (for example, Left Eye 20/20).
15. If the patient wears corrective lenses, record the results using $\overline{CC}$ (if your office uses this abbreviation for “with correction”) in front of the abbreviation (for example, $\overline{CC}$ Both Eyes 20/20).

RATIONALE: *For charting accuracy, vision correction must be noted using your office format.*

16. Note and record any observations of squinting, head tilting, excessive blinking, or tearing.
17. Ask the patient to keep both eyes open and to identify the color of the two colored bars on the Snellen chart, and record the results in the patient’s chart.

RATIONALE: *This step is sometimes done as a basic color vision screening.*

18. Clean the occluder with a gauze square dampened with alcohol.
19. Properly dispose of the gauze square and wash your hands.

RATIONALE: *Maintain principles of aseptic technique at all times.*

Near Vision

20. Wash your hands, identify the patient, introduce yourself, and explain the procedure.
21. Have the patient hold one of the following at normal reading distance (approximately 14 to 16 inches): Jaeger, Richmond pocket, or similar chart or card.

(a)

FIGURE Procedure 43-2 Step 21 (a) Have the patient hold the card at a comfortable reading distance.

© McGraw-Hill Education

(b)

FIGURE Procedure 43-2 Step 21 (b) This near vision chart is used to test the ability to see objects at a normal reading distance. Reprinted with permission of Richmond Products, Inc.

22. Ask the patient to keep both eyes open and to read or identify the letters, symbols, or paragraphs.
RATIONALE: If both eyes are not open, results may not be accurate.
23. Record the smallest line read without error.
24. If the card is laminated, clean it with a gauze square dampened with alcohol.
25. Properly dispose of the gauze square and wash your hands.
RATIONALE: Maintain principles of aseptic technique at all times.

(c)

FIGURE Procedure 43-2 Step 21 (c) The Richmond pocket vision screener is also used to test near vision. Reprinted with permission of Richmond Products, Inc.

Color Vision

26. Wash your hands, identify the patient, introduce yourself, and explain the procedure.
27. Hold one of the following color charts or books at the patient's normal reading distance (approximately 14 to 16 inches): Ishihara, Richmond pseudoisochromatic, or similar color-testing system.

(a)

(b)

FIGURE Procedure 43-2 Step 27 (a) Have the patient hold the chart at a comfortable reading distance. (b) The Richmond pseudoisochromatic color chart is used to test a person's ability to see colors.

© McGraw-Hill Education; Reprinted with permission of Richmond Products, Inc.

28. Ask the patient to tell you the number or symbol within the colored dots on each chart or page.
29. Proceed through all the charts or pages, usually totaling 24.
30. Record the number correctly identified and failed with a slash between them (for example, 23 passed/1 failed).
31. If the charts are laminated, clean them with a gauze square dampened with alcohol.
32. Properly dispose of the gauze square and wash your hands.
RATIONALE: *Maintain principles of aseptic technique at all times.*
33. Document the results after you have completed the procedure (Refer to Progress Note).

PROCEDURE 43-3 Administering Eye Medications

WORK // DOC

Procedure Goal: To instill (introduce) medication into the eye for treatment of certain eye disorders

OSHA Guidelines:

Materials: Medication (drops, cream, or ointment), tissues, eye patch (if applicable), progress note/patient chart

Method:

1. Identify the patient, introduce yourself, and explain the procedure.

2. Review the licensed practitioner's medication order. This should include the patient's name, drug name, concentration, number of drops (if a liquid), into which eye(s) the medication is to be administered, and the frequency of administration.
RATIONALE: *The licensed practitioner's order must be followed exactly.*
3. Compare the drug with the medication order three times and complete a check of the rights of medication administration, including the right patient, medication, doses, route, time, and documentation.
RATIONALE: *To ensure necessary accuracy.*
4. Ask whether the patient has any known allergies to substances contained in the medication.

5. Wash your hands and put on gloves.
6. Assemble the supplies.
7. Ask the patient to lie down or to sit back in a chair with the head tilted back.
8. Give the patient a tissue to blot excess medication as needed.
9. Remove an eye patch, if present.
10. Instruct the patient to look at the ceiling and to keep both eyes open during the procedure.
11. With a tissue, gently pull the lower eyelid down by pressing downward on the patient's cheekbone just below the eyelid with your nondominant hand. This pressure will open a pocket of space between the eyelid and the eye.

FIGURE Procedure 43-3 Step 11 Use a tissue to press down on the patient's cheekbone just below the eyelid, opening up a pocket of space between the eyelid and the eye.

© Ken Lax

Eyedrops

12. Resting your dominant hand on the patient's forehead, hold the filled eyedropper or bottle approximately ½ inch from the conjunctiva.
- RATIONALE:** *Touching the patient's skin with the dropper or bottle tip will cause contamination.*

FIGURE Procedure 43-3 Step 12 The medication container should be approximately ½ inch from the conjunctiva as you prepare to instill drops into the patient's eye.

© Ken Lax

13. Drop the prescribed number of drops into the pocket. If any drops land outside the eye, repeat instilling the drops that missed the eye.

Creams or Ointments

14. Rest your dominant hand on the patient's forehead and hold the tube or applicator above the conjunctiva.
15. Without touching the eyelid or conjunctiva with the applicator, evenly apply a thin ribbon of cream or ointment along the inside edge of the lower eyelid on the conjunctiva, working from the medial (inner) to the lateral (outer) side.

RATIONALE: *Touching the patient's skin with the applicator will cause contamination.*

FIGURE Procedure 43-3 Step 15 Apply a thin ribbon of cream or ointment along the inside of the lower eyelid on the conjunctiva.

© Ken Lax

All Medications

16. Release the lower lid and instruct the patient to gently close the eyes.
17. Repeat the procedure for the other eye as necessary.
18. Remove any excess medication by wiping each eyelid gently with a fresh tissue from the medial to the lateral side.
19. Apply a clean eye patch to cover the entire eye, if ordered.
20. Ask whether the patient felt any discomfort and observe for any adverse reactions. Notify the licensed practitioner as necessary.
21. Instruct the patient on self-administration of medication and patch application, if ordered.
22. Ask the patient to repeat the instructions.

FIGURE Procedure 43-3 Step 18 Use a tissue to remove excess medication from the eyelid.

© Ken Lax

23. Provide written instructions.
24. Properly dispose of used disposable materials.
25. Remove gloves and wash your hands.

26. Document administration in the patient's chart. Include the drug, the concentration, the number of drops or amount, the time of administration, and the eye(s) that received the medication (Refer to Progress Note).

PROCEDURE 43-4 Performing Eye Irrigation

WORK // DOC

Procedure Goal: To flush the eye to remove foreign particles or relieve eye irritation

OSHA Guidelines:

Materials: Patient chart/progress note, sterile irrigating solution, sterile basin, sterile irrigating syringe and kidney-shaped basin, tissues

Method:

1. Identify the patient, introduce yourself, and explain the procedure.
2. Review the licensed practitioner's order. This should include the patient's name, the irrigating solution, the volume of solution, and for which eye(s) the irrigation is to be performed.
3. Compare the solution with the instructions three times, checking the rights of medication administration.
RATIONALE: To ensure necessary accuracy.
4. Wash your hands and put on gloves, a gown, and a face shield.
RATIONALE: Splashing is possible when a syringe is used.
5. Assemble supplies.
6. Ask the patient to lie down or to sit with the head tilted back and to the side that is being irrigated. The solution should not spill over into the other eye.

RATIONALE: Cross-contamination between the eyes must be avoided.

7. Place a towel or a disposable waterproof underpad over the patient's shoulder. Have the patient hold the kidney-shaped basin at the side of the head next to the eye to be irrigated.
8. Pour the solution into the sterile basin.
9. Fill the irrigating syringe with solution (approximately 50 mL).
10. Hold a tissue on the patient's cheekbone below the lower eyelid with your nondominant hand and press downward to expose the eye socket.
11. Holding the tip of the syringe ½ inch away from the eye, direct the solution onto the lower conjunctiva from the inner to the outer aspect of the eye. (Avoid directing the solution against the cornea because it is sensitive; do not use excessive force.)

RATIONALE: To avoid contamination, do not let the tip touch the eye or skin. Excessive force could damage the cornea.

12. Refill the syringe and continue irrigation until the prescribed volume of solution is used.
13. Dry the area around the eye with tissues or gauze squares.
14. Properly dispose of used disposable materials.
15. Remove your gloves, gown, and face shield, and wash your hands.
16. Record the following in the patient's chart: procedure, type of solution, amount of solution used, time of administration, and eye(s) irrigated.
17. Put on gloves and clean the equipment and room according to OSHA guidelines.

Procedure Goal: To determine how well a patient hears

OSHA Guidelines:

Materials: Patient chart/progress note, audiometer, headset, graph pad (if applicable), alcohol, gauze squares

Method:

Infants and Toddlers

1. Identify the patient and introduce yourself.
2. Wash your hands.
3. Pick a quiet location.
4. The patient can be sitting, lying down, or held by the parent.
5. Instruct the parent to be silent during the procedure.
6. Position yourself so that your hands are behind the child's right ear and out of sight.
RATIONALE: *You want the child to respond to sound, not to sight.*
7. Clap your hands loudly. Observe the child's response. (Never clap directly in front of the ear because this can damage the eardrum. As an alternative to clapping, use devices such as rattles or clickers (which may be available in the office) to generate sounds of varying loudness.)
8. Record the child's response as positive or negative for loud noise.
9. Position one hand behind the child's right ear, as before.
10. Snap your fingers. Observe the child's response.
11. Record the response as positive or negative for moderate noise.
12. Repeat steps 6 through 11 for the left ear.
13. Document the information (Refer to Progress Note).

Adults and Children

1. Wash your hands, identify the patient, introduce yourself, and explain the procedure.
2. Clean the earpieces of the headset with a sanitizing wipe according to the manufacturer's instructions.
RATIONALE: *Maintain aseptic technique at all times.*
3. Have the patient sit with his back to you.
RATIONALE: *To prevent the patient from using visual clues to pass the hearing test*
4. Assist the patient in putting on the headset and adjust it until it is comfortable.
5. Tell the patient he will hear tones in the right ear.
6. Tell the patient to raise his finger or press the indicator button when he hears a tone.
7. Set the audiometer for the right ear.
8. Set the audiometer for the lowest range of frequencies and the first degree of loudness (usually 15 decibels). (When using automated audiometers, follow the instructions printed in the user's manual.)
9. Press the tone button or switch and observe the patient.
10. If the patient does not hear the first degree of loudness, raise it two or three times to greater degrees, up to 50 or 60 decibels.
11. If the patient indicates that he has heard the tone, record the setting on the graph.
12. Change the setting to the next frequency. Repeat steps 9, 10, and 11.
13. Proceed to the midrange frequencies. Repeat steps 9, 10, and 11.
14. Proceed to the high-range frequencies. Repeat steps 9, 10, and 11.
15. Set the audiometer for the left ear.
16. Tell the patient that he will hear tones in the left ear and ask him to raise his finger or press the indicator button when he hears a tone.
17. Repeat steps 8 through 14.
18. Have the patient remove the headset.
19. Clean the earpieces with a sanitizing wipe.

PROCEDURE 43-6 Administering Eardrops

WORK // DOC

Procedure Goal:

To instill medication into the ear to treat certain ear disorders

OSHA Guidelines:

Materials:

Patient chart/progress note, liquid medication, cotton balls

Method:

1. Identify the patient, introduce yourself, and explain the procedure.
2. Check the licensed practitioner's medication order. It should include the patient's name, drug name, concentration, number of drops, into which ear(s) the medication is to be administered, and frequency of administration.
3. Compare the drug with the instructions three times, checking the rights of medication administration.

RATIONALE: *To ensure necessary accuracy.*

4. Ask whether the patient has any allergies to ear medications.
5. Wash your hands and put on gloves.
6. Assemble supplies.
7. Warm the medication with your hands or by placing the bottle in a pan of warm water.

RATIONALE: *Internal ear structures are very sensitive to extreme heat or cold. Administering cold medications can result in severe vertigo (dizziness) or nausea.*

8. Have the patient lie on his or her side with the ear to be treated facing up.
9. Straighten the ear canal by pulling the auricle upward and outward for adults, down and back for infants and children.

RATIONALE: *Straightening the ear canal ensures that the medication reaches its destination.*

10. Hold the dropper ½ inch above the ear canal.

RATIONALE: *The dropper must not be contaminated by touching the patient's skin or any other surface.*

(a)

(b)

11. Gently squeeze the bottle or dropper bulb to administer the correct number of drops.
12. Have the patient remain in this position for 10 minutes.

FIGURE Procedure 43-6 Step 11 Apply slow, gentle pressure to the dropper bulb so that you can count the drops and administer the prescribed number.

© Terry Wild Studio

13. If ordered, loosely place a small wad of cotton in the outermost part of the ear canal.
14. Note any adverse reaction, notifying the licensed practitioner as necessary.
15. Repeat the procedure for the other ear, if ordered.
16. Instruct the patient on how to administer the drops at home.
17. Ask the patient to repeat the instructions.
RATIONALE: *For maximum effectiveness, it is important that the patient understands how to correctly continue treatment at home.*
18. Provide written instructions.
19. Remove the cotton after 15 minutes.
20. Properly dispose of used disposable materials.
21. Remove gloves and wash your hands.
22. Record in the patient's chart the medication, the concentration, the number of drops, the time of administration, and which ear(s) received the medication (Refer to Progress Note).

PROCEDURE 43-7 Performing Ear Irrigation

WORK // DOC

Procedure Goal:

To wash out the ear canal to remove impacted cerumen, relieve inflammation, or remove a foreign body

OSHA Guidelines:

Materials:

Patient chart/progress note, fresh irrigating solution, clean basin, clean irrigating syringe, towel or absorbent pad, kidney-shaped basin, cotton balls

Method:

1. Identify the patient, introduce yourself, and explain the procedure.

2. Check the licensed practitioner's order. It should include the patient's name, the irrigating solution, the volume of solution, and for which ear(s) the irrigation is to be performed. If the practitioner has not specified the volume of solution, use the amount needed to remove the wax.
3. Compare the solution with the instructions three times, checking the rights of medication administration.
RATIONALE: *To ensure necessary accuracy.*
4. Wash your hands and put on gloves, a gown, and a face shield.
RATIONALE: *Splashing is possible when a syringe is used.*
5. Look into the patient's ear to identify cerumen or a foreign body needing to be removed. You will know when you have completed the irrigation when the cerumen or foreign body is removed.
RATIONALE: *Identifying the cerumen or foreign body visually will help you assess when you have successfully completed the irrigation.*
6. Assemble the supplies.
7. If the solution is cold, warm it to body temperature by placing the bottle in a pan of warm water.

FIGURE Procedure 43-7 Step 7 Warm the irrigation solution in a pan of warm water.

© McGraw-Hill Education

RATIONALE: Internal ear structures are very sensitive to extreme heat or cold. Administering cold liquids can result in severe vertigo or nausea.

8. Have the patient sit or lie on his or her back with the ear to be treated facing you.
9. Place a towel or disposable waterproof underpad over the patient's shoulder (or under the head and over the shoulder if the patient is lying down) and have the patient hold the kidney-shaped basin under the ear.
10. Pour the solution into the other basin.

11. If necessary, gently clean the external ear with cotton moistened with the solution.
12. Fill the irrigating syringe with solution (approximately 50 mL).
13. Straighten the ear canal by pulling the auricle upward and outward for adults.

RATIONALE: Straightening the ear canal allows the solution to reach its destination.

14. Holding the tip of the syringe ½ inch from the opening of the ear and tilted toward the top of the ear canal, slowly instill the solution into the ear. Allow the fluid to drain out during the process.

RATIONALE: Do not contaminate the syringe by allowing it to touch the patient or by allowing the draining fluid to touch it.

15. Refill the syringe and continue irrigation until the canal is cleaned or the solution is used up.
16. Dry the external ear with a cotton ball and, if ordered, leave a clean cotton ball loosely in place for 5–10 minutes.
17. If the patient becomes dizzy or nauseated, allow him or her time to regain balance before standing up. Assist the patient as needed.
18. Properly dispose of used disposable materials.
19. Remove your gloves, gown, and face shield, and wash your hands.
20. Record the following in the patient's chart: procedure and result, amount of solution used, time of administration, and ear(s) irrigated.
21. Put on gloves and clean the equipment and room according to OSHA guidelines.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
43.1 Describe the medical assistant's role in eye exams and procedures performed in a medical office.	The medical assistant may assist or perform some of the procedures that involve measuring various aspects and functions of the eye, such as visual acuity, color vision, and intraocular pressure.
43.2 Discuss various eye disorders encountered in a medical office.	Disorders of the eye include those of the external eye structures, such as blepharitis, ptosis, and sty; disorders of the anterior eye structures, such as conjunctivitis and corneal abrasions; disorders involving internal eye structures, such as cataracts, glaucoma, iritis, and retinal disorders; and refractive disorders, such as myopia, hyperopia, astigmatism, and presbyopia.
43.3 Identify ophthalmic exams performed in the licensed practitioner's office.	Ophthalmic exams performed in the licensed practitioner's office include inspecting internal eye structures; testing visual fields; glaucoma testing; inspecting external eye structures; and refraction exams.
43.4 Summarize ophthalmologic procedures and treatments.	Ophthalmologic procedures and treatments include administering eye medications such as eyedrops and ointments and performing eye irrigation.
43.5 Describe the medical assistant's role in otology.	Medical assistants in an otology office may assist with or perform auditory screening, administer ear medications, perform ear irrigations, and help with diagnostic tests such as tympanometry.

LEARNING OUTCOMES	KEY POINTS
43.6 Describe disorders of the ear encountered in the medical office.	Ear diseases and disorders include those of the outer ear, such as cerumen impaction, otitis externa, and pruritus; middle ear disorders, such as otitis media, mastoiditis, otosclerosis, and ruptured eardrum; and those of the inner ear, such as labyrinthitis, Ménière's disease, presbycusis, tinnitus, and hearing loss.
43.7 Recall various hearing and other diagnostic ear tests.	Hearing and other diagnostic ear tests include audiometry and tympanometry.
43.8 Summarize ear procedures and treatments.	Ear treatments and procedures include administration of ear medications, ear irrigation, microscope-aided earwax or foreign body removal, hearing aid fitting, and cochlear implants.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall Valarie from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. What is the medical assistant's role during the eye irrigation?
2. What are some of the reasons a licensed practitioner might order an eye irrigation procedure?

EXAM PREPARATION QUESTIONS

1. (LO 43.2) Which of the following is the common name for an inflammation of the conjunctiva?
 - a. Pruritus
 - b. Pink eye
 - c. Blepharitis
 - d. Iritis
 - e. Hordeolum
2. (LO 43.2) Drooping of the upper eyelid is known as
 - a. Astigmatism
 - b. Sty
 - c. Ptosis
 - d. Amblyopia
 - e. Conjunctivitis
3. (LO 43.5) An otologist treats which of the following disorders?
 - a. Glaucoma
 - b. Refractive disorders
 - c. Mastoiditis
 - d. Cataracts
 - e. Strabismus
4. (LO 43.6) Ringing in the ears is known as
 - a. Presbycusis
 - b. Tinnitus
 - c. Ménière's disease
 - d. Labyrinthitis
 - e. Otitis media
5. (LO 43.2) The buildup of which fluid causes glaucoma?
 - a. Aqueous humor
 - b. Lacrimal fluid
 - c. Vitreous humor
 - d. Cerumen
 - e. Perilymph
6. (LO 43.2) Which of the following is *not* a visual disturbance?
 - a. Presbyopia
 - b. Astigmatism
 - c. Refractive error
 - d. Presbycusis
 - e. Hyperopia

7. (LO 43.3) Which of the following would be determined by a refraction exam?
 - a. Astigmatism
 - b. Blepharitis
 - c. Corneal ulcers
 - d. Diabetic retinopathy
 - e. Strabismus
8. (LO 43.6) Which of the following would improve communication with a hearing-impaired patient?
 - a. Speak very loudly
 - b. Speak in clear, low-pitched tones
 - c. Speak directly into the patient's ear
 - d. Overemphasize your lip movements so that the patient can read your lips
 - e. Write everything down for the patient to read
9. (LO 43.7) The units for measuring the relative intensity of sounds on a scale from 0 to 130 are
 - a. Frequencies
 - b. Waves
 - c. Audiometers
 - d. Periods
 - e. Decibels
10. (LO 43.6) Sensorineural hearing loss is caused by
 - a. Damage to the inner ear
 - b. Impacted cerumen
 - c. Otitis media
 - d. Tinnitus
 - e. Otosclerosis

Go to CONNECT to see an animation exercise about *Hearing Loss: Sensorineural*.

SOFT SKILLS SUCCESS

You are assigned to assist with an audiogram on a patient. You have not yet used the new machine that the office just purchased for the audiogram. When you enter the room to introduce yourself to the patient, he looks at you blankly and does not appear to understand.

1. How should you proceed with the new equipment?
2. How should you interact with the patient?

Go to PRACTICE MEDICAL OFFICE and complete the modules Clinical - Work Task Proficiencies and Clinical - Interactions.

Assisting with Minor Surgery

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Peter Smith	3/28/19XX	NKA
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	428-69-544	Started swimming last week

Peter Smith is a 73-year-old male with a history of mild depression. He arrives at the clinic holding a bloody towel over his left forearm. He is taken immediately back to the treatment area. He states that he cut himself with a large knife while cutting a pineapple. You take his vital signs while waiting for the physician. You notice the blood is leaking through the towel. You need to control the bleeding.

© Image Source/Getty Images RF

You put on PPE, most importantly gloves, and apply a large dressing over the area, holding firm pressure. The physician arrives, examines the patient, and determines that the patient will need sutures. While you are preparing Mr. Smith for his wound repair procedure, he tells you that he recently started swimming for exercise and is going to the Bahamas for a snorkeling trip in 2 weeks.

He wants to know if this will ruin his trip.

Keep Mr. Smith in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 44, you will be able to:

- 44.1** Define the medical assistant's role in minor surgical procedures.
- 44.2** Describe surgical procedures performed in an office setting.
- 44.3** Identify the instruments used in minor surgery and describe their functions.
- 44.4** Describe the procedures for medical and sterile asepsis in minor surgery.
- 44.5** Summarize the medical assistant's duties in preoperative procedures.
- 44.6** Describe the medical assistant's duties during an operative procedure.
- 44.7** Implement the medical assistant's duties in the postoperative period.

KEY TERMS

- | | |
|----------------------|---------------------|
| abscess | laceration |
| anesthesia | ligature |
| anesthetic | maturation phase |
| approximate | needle biopsy |
| cryosurgery | postoperative |
| debridement | preoperative |
| electrocauterization | proliferation phase |
| formalin | puncture wound |
| incision | sterile field |
| inflammatory phase | suture |
| intraoperative | swaged needle |

- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.9** Assist provider with a patient exam
- III.C.3** Define the following as practiced within an ambulatory care setting:
 - (a) medical asepsis
 - (b) surgical asepsis
- III.P.2** Select appropriate barrier/personal protective equipment (PPE)
- III.P.3** Perform handwashing
- III.P.6** Prepare a sterile field
- III.P.7** Perform within a sterile field
- III.P.8** Perform wound care
- III.P.9** Perform dressing change
- III.P.10** Demonstrate proper disposal of biohazardous material
 - (a) sharps
 - (b) regulated wastes
- V.P.4** Coach patients regarding:
 - (b) health maintenance
 - (c) disease prevention
 - (d) treatment plan
- X.P.3** Document patient care accurately in the medical record

2. Anatomy and Physiology

- c. Identify diagnostic and treatment modalities as they relate to each body system

9. Clinical Procedures

- a. Practice standard precautions and perform disinfection/sterilization techniques
- e. Perform specialty procedures including but not limited to minor surgery, cardiac, respiratory, OB-GYN, neurological, gastroenterology

10. Medical Laboratory Procedures

- c. Dispose of biohazardous materials

► Introduction

Minor surgical procedures are frequently performed in ambulatory care settings and office practices. Assisting with minor surgery requires a variety of duties and skills. As a medical assistant, you must be knowledgeable of the types of procedures performed where you are employed. You need to know how to prepare the patient for surgery, assist the practitioner during surgery, and care for the patient after surgery. Because all types of surgery require surgical asepsis, a working knowledge of this technique is mandatory.

► The Medical Assistant's Role in Minor Surgery

LO 44.1

Medical assistants play an important role in all aspects of minor surgical procedures. You will perform administrative tasks prior to the patient's surgery, including completing forms for insurance and obtaining signed informed consent from the patient. You will explain basic aspects of the surgical procedure and answer the patient's questions. Informing

the doctor of all current prescription and over-the-counter (OTC) medications that the patient is currently taking is also an administrative task. Finally, you will make sure the patient knows how to follow the appropriate presurgical instructions.

In addition to presurgical administrative tasks, you also will perform many tasks directly related to the surgical procedure. You will make sure the surgical room is clean, neat, and properly lit. You will see that all the equipment, instruments, and supplies the doctor will use are clean, disinfected or sterilized, and properly arranged. You also may function as an unsterile assistant, ensuring the safety and comfort of the patient during the procedure and performing other duties. At other times, you may directly assist with the surgical procedure in a sterile capacity.

Following the surgical procedure, you will help dress the wound and perform other postoperative patient care, making sure the patient is not experiencing ill effects from the surgery or local anesthetic. You will educate the patient about wound care and proper procedures to follow after surgery and make sure the patient has safe transportation home. You also will clean the room and prepare it for the next patient.

► Surgery in the Physician's Office LO 44.2

Minor surgical procedures are those that can be safely performed in the physician's office or clinic without general anesthesia. **Anesthesia** is a loss of sensation, particularly the feeling of pain. An **anesthetic** is a medication that causes anesthesia. A general anesthetic affects the entire body, whereas a local anesthetic affects only a particular area. Minor surgical procedures typically involve the use of a local anesthetic in the form of an injection or a cream applied to the skin.

Minor surgery is performed for many reasons, whether it be to diagnose an illness or repair an injury. Other procedures may be elective, or optional. Removal of a wart, skin tag (a small outgrowth of skin, occurring frequently on the neck as people get older), or other small growth for cosmetic reasons is an elective procedure. Some of the common minor surgical procedures you may assist the doctor with include the following:

- Repair of a laceration
- Irrigation and cleaning of a puncture wound
- Wound debridement
- Removal of foreign bodies
- Removal of small growths
- Removal of a nail or part of a nail
- Drainage of an abscess
- Collection of a biopsy specimen
- Cryosurgery
- Laser surgery
- Electrocauterization

Common Surgical Procedures

Many surgical procedures are routinely performed in a doctor's office. You may perform some of these procedures on your own. For example, you may change dressings for surgical wounds, and under a doctor's orders, you may remove sutures (commonly called stitches) or staples after wounds have healed. Any procedure that requires an **incision** (a surgical wound made by cutting into body tissue) must be performed by a doctor.

Draining an Abscess An **abscess** is a collection of pus (white blood cells [WBCs], bacteria, and dead skin cells) that forms as a result of infection. A protective lining can form around an abscess and prevent it from healing. In such a case, the physician may make an incision in the lining of the abscess. This procedure is known as an incision and drainage (I&D). The physician may allow the abscess to drain on its own or insert a drainage tube.

Obtaining a Biopsy Specimen A biopsy specimen is a small amount of tissue removed from the body for examination under a microscope. Most biopsies involve cutting the tissue. For a **needle biopsy**, the doctor uses a needle and syringe to aspirate (withdraw by suction) fluid or tissue cells. (The procedure in the *Assisting in Other Medical Specialties*

chapter describes how to assist with a needle biopsy.) All specimens must be placed in a preservative, most commonly a 10% **formalin** solution (a dilute solution of formaldehyde), to prevent changes in the tissue.

Mole Removal A mole, also called a *nevus*, is a small, discolored area of the skin. It may be raised or flat. Any mole that changes shape, size, or color should be evaluated for possible removal. Moles are typically removed by excision or by slicing flush with the skin. If the mole is excised, sutures are usually necessary. Moles that are removed by slicing flush with the skin do not require sutures but may need to be cauterized.

Caring for Wounds A wound is any break in the skin. The break may be accidental or intentional, as from a surgical procedure. There are several types of accidental wounds. A **laceration** is a jagged, open wound in the skin that can extend down into the underlying tissue. The jagged edges may have to be cut away before the wound is closed. A **puncture wound** is a deep wound caused by a sharp object. (See the *Emergency Preparedness* chapter for further information on types and care of accidental wounds.) Both surgical and accidental wounds require special care to prevent infection. Proper wound care that promotes healing without infection is discussed in the *Caution: Handle with Care* feature.

Cleaning a Wound The first step in preventing a non-surgical wound from becoming infected is careful cleansing. First, clean around the wound with soap and water. Then, it must be irrigated with sterile saline solution or sterile water, applied with a syringe and needle.

Debridement is the removal of debris or dead tissue from a wound. This special type of cleaning may be required for a wound that has dead or sloughing tissue. This procedure helps to expose healthy tissue and promote healing. The doctor may use one of a number of wound debridement methods:

- Surgical—cutting away tissue with scalpel and scissors
- Chemical—using special compounds to dissolve tissue
- Mechanical—applying a dressing that sticks to the wound, removing dead tissue when the dressing is removed, or irrigating the wound with sterile saline
- Autolytic—applying a dressing that helps the body's natural fluids dissolve dead tissue

Wound Healing It is important to know how a wound heals so that you can care for it properly. A wound heals in three phases: inflammatory phase, proliferation phase, and maturation phase. The time it takes for a wound to heal depends on several factors, including the patient's age, nutritional status, and overall health. During the initial phase, or **inflammatory phase**, bleeding is reduced as blood vessels in the affected area constrict. Platelets, clotting factors, and WBCs play an important role in this phase. They seal the wound, clot the blood that has seeped into the area, and remove bacteria and debris from the wound. The wound contracts under the clot or scab that forms.

CAUTION: HANDLE WITH CARE

Conditions That Interfere with Fast, Effective Wound Healing

The goals for treating both surgical and nonsurgical wounds are similar: to heal the wound without infection and to preserve normal skin function and appearance. Nonsurgical wounds often involve conditions that do not promote fast, effective healing. In these cases, the wounds require special attention to ensure good results.

Many types of nonsurgical wounds contain foreign material that can lead to infection. For example, a child may have a deep laceration from landing on a dirty, broken bottle when falling off a bicycle. These types of wounds always need vigorous cleaning. Some may need debridement.

Wounds heal better when the edges are brought closely together, or approximated. Jagged edges in a laceration make approximation harder. It is also difficult to approximate crushed tissue, as you would see with fingers closed in a car door. Crushing disrupts a tissue's blood supply by rupturing blood vessels throughout the affected area. A physician might debride this type of wound with a scalpel to remove severely damaged tissue and achieve a clean wound edge before suturing.

After a surgical or nonsurgical wound is closed and sutured, it is essential to keep the wound clean and dry to help prevent infection. Infection delays the healing process and can have other serious consequences.

A sutured wound heals more quickly and smoothly when no scab forms because the migrating skin cells encounter no barrier to their movement. Proper postoperative care, including daily cleaning with soap and water or a mild antiseptic, keeps a wound scab-free. Although skin cells migrate across the space of a wound more easily in a somewhat moist environment, a wet wound offers the ideal conditions for bacteria to grow and

cause infection. Covering a wound with a clean, dry dressing helps prevent infection.

Wound healing may be delayed in a number of instances not directly related to the surgery or injury. The presence of any of the following conditions can put a patient at risk for wound healing problems. Wounds in such patients may require extra attention and care.

- **Poor circulation.** This condition results in inadequate supplies of nutrients, blood cells, and oxygen to the wound, all of which delay the healing process.
- **Aging.** Physiologic changes that occur with age can decrease a person's resistance to infection.
- **Diabetes.** Patients with diabetes experience changes in their artery walls that result in poor circulation to peripheral tissues. These patients also may have a decreased resistance to infection.
- **Poor nutrition.** Patients who are undernourished, particularly those who are deficient in protein or vitamin C, do not have the physiologic resources for vigorous healing.
- **High levels of stress.** An increase in stress-related hormones can decrease resistance to infection.
- **Weakened immune system.** Patients who are on certain medications or who have certain chronic diseases may have weakened immune systems, putting them at increased risk of infection.
- **Obesity.** When someone is obese, the circulation directly under the skin is often poor, leading to slow healing.
- **Smoking.** Nicotine constricts the blood vessels in the skin, reducing circulation to the wound area and slowing healing.

During the second phase, or **proliferation phase**, new tissue forms. Skin cells at the edges of the wound begin to move together to close off the wound. The scab that often forms over a wound actually slows down this movement of skin cells. The edges of the wound eventually come together and form a continuous layer, closing off the wound.

The proliferation phase speeds up if the edges of an incision or a nonsurgical wound are **approximated**, or brought together so that the tissue surfaces are close. This intervention protects the area from further contamination and minimizes scab and scar formation. Small wounds can be held together with butterfly closures, sterile strips, or adhesive. Skin adhesive is a special type of glue used for closing small wounds. Larger wounds or those subject to strain may require suturing or stapling.

The **maturation phase** (the third phase) involves the formation of scar tissue. Scar tissue is important for closing large, gaping, or jagged wounds. The continuous layer of skin cells formed during the second phase becomes thicker and pushes

off the scab, leaving a scar. Scar tissue contains no nerves or blood vessels and lacks the resilience of skin.

Closing a Wound Sutures are surgical stitches a physician uses to close a wound. Suture materials, or **ligature**, can be either absorbable or nonabsorbable. The type and location of the wound will determine the type of suture material the healthcare practitioner chooses. The body breaks down absorbable sutures, so they do not require removal after the wound has healed. If a wound is particularly deep, the healthcare practitioner may need to suture in layers, from inside to outside. In this case, absorbable sutures are used for the inner suturing. Removable (nonabsorbable) sutures are generally

used for the outside layer. Nonabsorbable ligature must be removed after wound healing is well under way. Sutures are discussed in greater detail later in the chapter.

Staples may be used to bring the edges of a wound together if there is considerable stress on the incision. For example, a long and deep surgical wound or a wound across the leg would have a strong tendency to gape open if not firmly secured. Surgical staples look somewhat like ordinary staples. They are inserted into the skin with a disposable staple unit.

Special Minor Surgical Procedures

Some types of minor surgical procedures require special surgical instruments. These procedures include laser surgery, cryosurgery, and electrocauterization. They all remove excess or abnormal tissue, as in the case of warts or skin lesions, and usually require surgical aseptic technique because they break the integrity of the skin.

Laser Surgery A laser emits an intense beam of light that is used to cut away tissue. Laser surgery is sometimes preferred over conventional surgery because it causes less damage to surrounding healthy tissue than does conventional surgery. Laser surgery also promotes quick healing and helps prevent infection.

When a laser is used in an office setting, close blinds and shades to keep out stray light. Remove any items—like the paper from wrapped sterile instruments or syringes—that could catch fire if they came in contact with the laser beam. Cover any shiny or reflective surfaces or use nonshiny instruments. Make sure that everyone in the room, including the patient, wears special safety goggles to protect the eyes. You should have a fire extinguisher in the room where it is out of the way but easily accessible. Post a standard laser warning placard in the room's entryway, per Occupational Safety and Health Administration (OSHA) regulations.

Position, drape, and prepare the patient as you would for conventional surgery. Place gauze around the surgical site and assist the physician with administration of a local anesthetic if requested. The physician uses the laser to vaporize the unwanted tissue; vaporized tissue is cleared away by the vacuum hose portion of the unit (see Figure 44-1). You may be asked to apply pressure to control any bleeding. Clean the wound with an antiseptic and apply a sterile dressing. Give the patient the normal instructions on wound care, including the recommendation to protect the site from sun exposure.

Cryosurgery The use of extreme cold to destroy unwanted tissue is called **cryosurgery**. Cryosurgery is often used to remove skin lesions and lesions on the cervix. Before cryosurgery, inform the patient that an initial sensation of cold will be followed by a burning sensation. Instruct the patient to remain as still as possible to prevent damage to nearby tissue.

The doctor may freeze the tissue by touching it with a cotton-tipped applicator dipped in liquid nitrogen or by spraying it with liquid nitrogen from a pressurized can. Sometimes,

FIGURE 44-1 Suction eliminates vaporized tissue as a physician uses a laser to remove a wart from a patient's hand.

© Barry Slaven Photography

a special cryosurgical instrument is used, most often during surgery on the cervix.

Make the patient aware that more than one freezing cycle may be necessary. A local anesthetic is usually not required because the cold itself reduces sensation in the area. After the procedure, the area is cleaned with an antiseptic and a sterile dressing may be applied. An ice pack may be applied to reduce swelling and pain relievers given for pain.

Reassure the patient that some pain, swelling, or redness is normal after a cryosurgical procedure. Encourage the patient to use ice and pain relievers as necessary. Let the patient know that a large, painful, bloody blister may form. Left undisturbed, the blister usually ruptures in about 2 weeks. It should be left intact to promote healing and prevent infection. The patient should call the doctor if a blister becomes too painful. Be sure to provide the patient with complete wound care instructions.

Electrocauterization This is a technique whereby a needle, probe, or loop heated by electric current destroys the target tissue. A physician may use **electrocauterization** to remove growths such as warts, to stop bleeding, and to control nosebleeds that either will not subside or continually recur.

Several types of electrocautery units are in use. Some are small, handheld units powered by battery or by ordinary household electric current. Other, larger units are designed for countertop placement or wall mounting. Some units use disposable probes and others employ reusable ones.

With certain units, a grounding pad or plate is placed on or under the patient's body during the procedure. This grounding completes the circuit and prevents electric shock to the patient, the physician, and staff members. Reassure the patient that grounding causes no discomfort.

A local anesthetic may be administered before the procedure. After electrocauterization, a scab or crust generally forms over the area. Healing may take 2 to 3 weeks. General wound care instructions are appropriate for this procedure, except that a dressing may be omitted to keep the area drier.

► Instruments Used in Minor Surgery

LO 44.3

The type of minor surgical procedure determines which surgical instruments are used. Surgical instruments have specific purposes and may be classified by function.

Cutting and Dissecting Instruments

Cutting and dissecting instruments have sharp edges and are used to cut (incise) skin and tissue. Figure 44-2 illustrates some of the basic cutting and dissecting instruments you will encounter. You must be careful when cleaning, sterilizing, and storing these instruments to avoid injuring yourself and to protect the instruments' sharp edges.

Scalpels A scalpel consists of a handle that holds a disposable blade. Scalpel handles are either reusable or disposable and vary in width and length. A scalpel's specific use determines the shape and size of its blade. General-purpose scalpels have wide blades and a straight cutting surface (Figure 44-3). A no. 15 blade is the most common one for performing minor procedures.

Take special care when handling a scalpel. If the physician requests a reusable scalpel handle, it is essential that you load and unload the blade correctly on the handle. Carefully follow these steps when loading and unloading a scalpel blade:

Steps for Loading a Scalpel Handle

1. Carefully grasp the blade with a needle holder, staying away from the sharp edge.
2. Ensure that the blade edge is pointed away from you and you are gripping the blade just above the blade slot.
3. Firmly hold the scalpel handle in your nondominant hand. Hold the handle in the center, not close to the blade lock.
4. Carefully slide the blade over the grooves of the blade lock until it snaps into place.
5. The blade should slide smoothly down the groove. If it jams, carefully slide it back up the blade lock while grasping the blade with the needle holder, realign the blade slot, and slide the blade back down the blade lock.
6. Never use your fingers to load a blade on a scalpel handle. The blade is very sharp and may slip, causing serious injury.

Steps for Unloading a Scalpel Handle

1. Using your nondominant hand, hold the scalpel handle in the center.
2. With the blade lock facing up, point the blade and handle downward over a sharps container (make sure the sharps container is well below the blade and the blade is not pointed toward anyone in the room).
3. Using the needle holder, grasp the angled edge of the blade near the blade lock.

FIGURE 44-2 These are typical cutting and dissecting instruments used in minor surgical procedures.

FIGURE 44-3 Scalpel blades come in various sizes and shapes, some of which are represented here.

4. Lift the blade slightly over the blade lock and slide it up to disengage the blade from the blade lock.
5. Immediately drop the blade into the sharps container.
6. Do not touch the blade with your fingers.
7. The blade handle is now ready for sanitization and sterilization.

A number of special blade removal devices are also available. These devices contain the blade in a case or box before removal. Follow the manufacturer's instructions for safe scalpel blade removal.

Scissors Surgical scissors come in various sizes. They may be straight or curved and have either blunt or pointed tips. Tissue scissors must be sharp enough to cut without damaging or ripping surrounding tissue. Suture scissors have blunt points and a curved blade. The lower blade is inserted under the suture material to cut it. Bandage scissors are used to remove dressings. They have a blunt lower blade to prevent injuring the skin next to the dressing. Clippers are scissor-like instruments used for cutting nails or thick materials.

Curettes The doctor uses a curette for scraping tissue. Curettes come in a variety of shapes and sizes and consist of a circular blade—actually a loop—attached to a rod-shaped handle. The blade is blunt on the outside and sharp on the inside. The inner part of the blade may also be serrated. Serrated blades may be used to take Pap (Papanicolaou) smears. Blunt curettes, known as Buck ear curettes, are used to remove wax from the ear canal when a large amount of cerumen has accumulated.

Grasping and Clamping Instruments

Special instruments are used for grasping and clamping tissue. Grasping instruments are used to hold surgical materials or to remove foreign objects, such as splinters, from the body. Clamping instruments are used to apply pressure and close off blood vessels. They also are used to hold tissue and other materials in position. Figure 44-4 shows some common grasping and clamping instruments.

Forceps Forceps are instruments that are commonly used to grasp or hold objects. Grasping types are usually shaped like tweezers and include thumb forceps and tissue forceps. Thumb forceps, also called smooth forceps, vary in shape and size. The blades of thumb forceps are tapered to a point and have small grooves at the tip. Tissue forceps (serrated forceps) have one or more fine teeth at the tips of the blades. When closed, these forceps hold tissue firmly. Holding forceps have handles with ratchets that lock the teeth in a closed position. Dressing, or sponge, forceps have ridges to hold a sponge or gauze when it is used to absorb body fluids.

Hemostats The most commonly used surgical instruments are hemostats. These surgical clamps vary in size and shape and are typically used to close off blood vessels. The serrated jaws of hemostats taper to a point. Like holding forceps, hemostats have handles that lock on ratchets, holding the jaws securely closed.

Towel Clamps Towel clamps are used to keep towels used for draping the surgical site in place during a surgical procedure. This stability is important in maintaining a sterile field.

Retracting, Dilating, and Probing Instruments

Retracting instruments are used to hold back the sides of a wound or an incision. Dilating and probing instruments may be used to enlarge, examine, or clear body openings, body cavities, or wounds. The shapes of these instruments vary with their functions. Some typical retracting, dilating, and probing instruments are shown in Figure 44-5.

Retractors The use of retractors allows greater access to and a better view of a surgical site. Some retractors must be held open by hand, while others have ratchets or locks to keep them open.

Dilators Dilators are slender, pointed instruments used to enlarge a body opening, such as a tear duct.

Probes A surgical probe is a slender rod with a blunt, bulb-shaped tip. Probes are used to explore wounds or body cavities and to locate or clear blockages.

Suture Material and Suturing Instruments

Suturing instruments are used to introduce suture materials into and retrieve them from a wound. Some carry the suture material, whereas others manipulate the suture carriers. Examples of suturing instruments are shown in Figure 44-6.

FIGURE 44-4 These are typical grasping and clamping instruments used in minor surgical procedures.

FIGURE 44-5 These are typical retracting, dilating, and probing instruments used in minor surgical procedures.

Suture Materials As a medical assistant, you need to be familiar with the various types of sutures. The healthcare practitioner will ask for a specific suture type based on several considerations, including the type and location of the wound. Sutures may be natural or synthetic, absorbable or nonabsorbable. The healthcare practitioner will choose a needle that causes the least possible trauma to the tissues. The needle may be curved or straight, cutting, blunt, or tapered. A **swaged needle** has the suture material permanently

attached to the needle. The needle may also have an eye where the suture material is manually threaded. It is important that you be able to quickly find information about the type of suture material in a package. Figure 44-7 illustrates the most common information found on a suture package.

General Features of Suture Materials Regardless of the type, suture materials have some general qualities in common:

Needles

FIGURE 44-6 These are typical suturing instruments.

FIGURE 44-7 Information about the suture material can be found on the package.

- Sterility
- Uniform diameter
- Tensile strength (resistance to breaking under tension or pull)
- Flexibility
- Ability to retain or hold a knot
- Low incidence of tissue reactivity

Suture Size Suture size is determined by the diameter or thickness of the strand. Sizes range from 11-0 (smallest) to 7 (largest). The number in front of the “0” determines the number of zeros. Remember, the more zeros in the size, the smaller the suture. For example, a 6-0 suture is smaller in diameter than a 3-0 suture. The sizes you will most often see used for minor surgical procedures are 6-0 to 3-0. Sutures sized 6-0 and 5-0 are used most often to close wounds of the face, lips, and eyebrow. Wounds of the sole of the foot generally require a suture that is thicker in diameter. These wounds are usually repaired with a 3-0 or 4-0 suture.

Suture Needles Surgical suture needles carry suture material, or ligature, through the tissue being sutured. They are either pointed or blunt at one end and may have an eye at the other end to hold suture material. Ligature often comes prepackaged with the needle already connected. Prepackaged suture needles with attached ligature (swaged) have no eye and produce less trauma to the tissue being sutured than do suture needles with eyes.

Suture needles may be straight, or they may be curved to allow deeper suture placement. Taper point needles (needles that taper into a sharp point) are used to suture tissues that are easily penetrated. They create only very small holes, thus minimizing tissue fluid leakage. Cutting needles (needles that have at least two sharpened edges) are used on tough tissues that are not easily penetrated, such as skin.

Several measurements are used to determine the size of a surgical needle. Needle length is the distance from the tip to the end, measuring along the body of the needle. Chord length is the straight-line distance from the tip to the end of the needle. (Chord length is not the same as needle length in curved needles.) The radius of a curved needle is determined by mentally continuing the curve of the needle into a full circle and finding the distance from the center of the circle to the needle body. The diameter is the thickness of the needle. Needle size generally corresponds to the size of suture material used. Smaller needles are used for delicate procedures, such as eye surgery or repair of a facial laceration. Larger needles are used for suturing wounds of less delicate parts of the body, such as the hands or legs.

Needle Holders Curved suture needles require special instruments to hold, insert, and retrieve them during suturing. Most needle holders look like hemostats with short, sturdy jaws.

Syringes and Needles

Sterile syringes and needles are used to inject anesthetic solutions, withdraw fluids, and obtain biopsy specimens. The

FIGURE 44-8 This laceration repair tray contains scissors, several pairs of forceps, a needle holder, and sterile gauze. Suture material must be added for the procedure.

© David Kelly Crow

size of the syringe and needle varies with the intended use. For example, a needle used to perform a biopsy is generally larger than needles used for most injections. (Syringes and needles used for injections are discussed and illustrated in the *Medication Administration* chapter.) Both syringes and needles are provided in individual sterile envelopes.

Instrument Trays and Packs

All the surgical instruments needed for a specific procedure are usually assembled beforehand. They are then sterilized together in a pack. Certain surgical supplies necessary for the procedure (such as gauze) are included in the pack because they, too, must be sterile. Surgical trays can be quickly set up with these instrument packs. Individually wrapped items also may be added as needed.

These are the common types of instrument trays:

- Laceration repair tray (see Figure 44-8)
- Laceration repair with debridement tray
- Incision and drainage tray
- Foreign body or growth removal tray
- Onychectomy (nail removal) tray
- Vasectomy (male sterilization procedure) tray
- Suture removal tray
- Staple removal tray

Asepsis

LO 44.4

Maintaining asepsis during surgical procedures is always a priority. It is critical to the health and safety of both the patient and the healthcare professional. The two levels of aseptic technique are medical asepsis (clean technique) and surgical asepsis (sterile technique). Medical asepsis is discussed in detail in the *Infection Control Fundamentals* chapter. You will use both levels of asepsis when assisting with minor surgery.

Personal Protective Equipment

Personal protective equipment, or PPE, includes all items used as a barrier between the wearer and potentially infectious or hazardous medical materials. PPE includes gloves, gowns, and masks and protective eyewear or face shields. OSHA regulations regarding PPE are discussed in detail in the *Infection Control Fundamentals* and *Infection Control Practices* chapters.

Gloves are of particular importance during surgical procedures. You should wear properly sized latex, nitrile, or vinyl gloves during any procedure that might expose you to potentially infectious or hazardous materials. (Gloves that are too big can catch on instruments or equipment and cause accidents.) When you wear gloves, you also protect the patient from any infectious organisms on your hands.

Vinyl, nitrile, and latex gloves can all prevent contamination of the hands with bacteria. Although latex gloves were the preference of healthcare professionals for many years, the incidence of latex allergy among healthcare professionals has grown. Allergic reactions to latex can range from a skin rash to shock and even death. Many healthcare institutions are switching to less allergenic low-powder or powderless non-latex gloves. The powder in latex gloves, which makes them easier to put on, is one of the primary sources of latex allergy. The latex protein that causes the allergy mixes with the powder. When the gloves are removed, the powder containing the latex protein becomes airborne and is inhaled.

If you work in a facility that uses latex gloves, take these steps to prevent latex allergy:

- If possible, use powder-free gloves only.
- Thoroughly dry hands after washing.
- Frequently apply non-oil-based lotion to the hands.
- Clean areas and equipment contaminated with latex-containing dust frequently.

If you notice latex allergy symptoms, consider consulting an allergist. You also should discuss your symptoms with your supervisor, who will recommend that you switch to hypoallergenic or vinyl gloves. If you have an allergy, the healthcare facility is required to provide nonlatex gloves for your use.

Sharps and Biohazardous Waste Handling and Disposal

Sharp medical and surgical instruments have great potential for transmitting infection through cuts and puncture wounds. Used scalpels, needles, syringes, and other sharp objects should be disposed of in a puncture-resistant sharps container.

All items other than sharps that have come in contact with tissue, blood, or body fluids must be disposed of in a leakproof plastic bag or container. The container must be either red or labeled with the orange-red biohazard symbol. The proper procedure for handling and disposing of sharps and biohazardous waste is discussed in detail in the *Infection Control Practices* chapter.

Surgical Asepsis

Surgical asepsis completely eliminates microorganisms. The goal of surgical asepsis is to control microorganisms before

they enter the body. To accomplish this goal, the items used in healthcare must be sterile (completely free of microorganisms). Surgical instruments are sterilized before use, and sterile technique procedures must be followed.

You will be expected to perform the following common procedures involving sterile technique:

- Creating a sterile field
- Adding sterile items to the sterile field
- Performing a surgical scrub
- Putting on sterile gloves
- Sanitizing, disinfecting, and sterilizing equipment

Creating a Sterile Field A **sterile field** is an area free of microorganisms that is used as a work area during a surgical procedure. Always be aware that the sterile field is understood to become contaminated and must be redone in the following circumstances:

- An unsterile item touches the field.
- Someone reaches across the field.
- The field becomes wet.
- The field is left unattended and uncovered.
- You turn your back on the field.

For more rules of sterile technique, see the *Caution: Handle with Care* feature.

The sterile field is often set up on a Mayo stand—a movable, stainless steel instrument tray on a stand. Adjust the stand so that the tray is slightly above waist level. Remember, items placed below waist level are considered contaminated. Before beginning, disinfect the Mayo stand with 70% isopropyl alcohol and allow it to dry.

To create the sterile field, cover the stand with two layers of sterile material. This material can be sterile disposable drapes, separately sterilized muslin towels, or the muslin towels that the surgical instruments are wrapped in before autoclaving to produce office-sterilized sterile instrument packs. Commercially prepared sterile instrument packs, usually with disposable paper wrappings, are also used to create a sterile field. Procedure 44-1, at the end of this chapter, describes how to prepare a sterile field and how to open sterile packages.

When assembling the necessary supplies, place all unsterile items that may be used during the procedure outside the sterile field. Unsterile items include items that are sterile on the inside but not on the outside, such as a sterile gauze pack or a sterile liquid such as alcohol, saline, or peroxide inside an unsterile bottle. Unsterile supplies should be arranged on a counter away from the sterile field. A typical arrangement of unsterile items used in surgery is shown in Figure 44-9. If you place an unsterile item within the sterile field, the field is no longer sterile and you must repeat the entire process.

Go to CONNECT to see a video exercise about
Creating a Sterile Field.

FIGURE 44-9 For each surgical procedure, unsterile surgical supplies must be gathered and arranged in an area separate from the sterile field.

© McGraw-Hill Education. David Moyer, photographer

Adding Sterile Items to the Sterile Field The outer 1 inch of the sterile field is considered contaminated. So before you add sterile items to the sterile field, carefully plan where you will place the instruments so that they are within the sterile field.

Instruments and Supplies If you have used sterile disposable drapes or separately sterilized muslin towels to create the sterile field, you will need to add the necessary instruments. Stand away from the sterile field and open the sterile instrument pack in the manner described in Procedure 44-1. Place the pack on a counter or hold it open in your hand. Transfer and arrange the instruments on the sterile field with sterile transfer forceps. Never reach across the sterile field.

Some instruments are sterilized individually in autoclave bags, and many sterile supplies are prepackaged. Stand away from the sterile field as you open an individual bag or package.

You can pull the flaps of the packaging partway apart, then snap (remove from position by a sudden movement) the item onto the sterile field from a distance of 8 to 12 inches. Alternatively, you can use sterile forceps to grasp and place the items in the sterile field.

Pouring Sterile Solutions Sterile solutions are often required during the surgical procedure to rinse or wash the wound. These can be added to the sterile field after the sterile instruments. Several sterile solutions are commonly used during minor surgical procedures, including sterile water and normal saline (0.9% sodium chloride).

Bottles of these sterile solutions come in a variety of sizes. Choose the smallest size that will supply the amount of solution needed during the procedure to help minimize cost, because unused solutions are typically discarded.

When pouring a solution, cover the label on the bottle with the palm of your hand to keep the label dry. Pour a small amount of the liquid into a liquid waste receptacle to clean the lip of the bottle. As you pour the solution into a sterile bowl on the field, hold the bottle at an angle to avoid reaching over the sterile area. Hold the bottle fairly close to the bowl without touching it. Pour the contents slowly to avoid splashing the drape, which would contaminate the field (see Figure 44-10).

When a sterile solution bottle is opened and may be used again during the procedure, do not let any unsterile object touch the inside of its cap. To accomplish this, place the cap on a clean location with the sterile inside of the cap facing up.

Performing a Surgical Scrub and Donning Sterile Gloves If you assist in a surgical procedure, you must perform a surgical scrub and wear sterile surgical gloves. Surgical scrub procedures are similar to those for aseptic handwashing, but there are several distinctions:

- A sterile scrub brush is used instead of a disposable nailbrush.
- Both the hands and the forearms are washed.

CAUTION: HANDLE WITH CARE

Rules for Sterile Technique

A sterile field is a microorganism-free area used during a surgical procedure. To maintain sterility throughout the procedure, follow surgical technique and adhere to these rules:

1. Do not touch a nonsterile article to a sterile article or area. This will cause the sterile area or article to be considered nonsterile.
2. If you are unsure about the sterility of an article or area, consider it nonsterile.
3. Unused, opened sterile supplies must be discarded or resterilized.
4. Packages must be wrapped or sealed in such a way that they can be opened without contamination.
5. The edges of wrappers (1-inch margin) covering sterile supplies and the outer lips of bottles and flasks containing sterile solutions are not considered sterile.
6. If a sterile surface or package becomes wet, it is considered contaminated and should not be used.
7. Do not reach over a sterile field when you are not wearing sterile clothing. This action contaminates the sterile field.
8. Keep your hands between your shoulders and your waist when wearing sterile gloves to maintain sterility.
9. Do not turn your back on a sterile field even if you are in a sterile gown. Your back is always considered contaminated.

FIGURE 44-10 When pouring a sterile solution for use on a sterile field, be careful not to splash the solution.

- The hands are kept above the elbows to prevent water from running from the arms onto washed areas.
- Sterile towels are used instead of paper towels.
- Sterile gloves are put on immediately after the hands are dried.

You may wonder why a surgical scrub is necessary if you are planning to wear sterile gloves. The answer is that there is always the possibility that a glove may be punctured. If the skin is as clean as possible, the risk of contamination from a punctured glove is minimized. Nevertheless, if a glove is damaged during a sterile procedure, you must consider anything touched by that glove after it is damaged to be contaminated. Contaminated items must be resterilized or replaced before you continue.

A surgical scrub removes microorganisms more effectively than does routine handwashing. Routine handwashing removes bacteria present on the skin's surface, whereas the surgical scrub removes bacteria in deeper layers of the skin—where the hair follicles and oil-producing glands exist. Procedure 44-2, at the end of this chapter, describes the process for performing a sterile scrub.

Sterile gloves are required for many procedures. You don sterile gloves after you perform the surgical scrub. The process for donning sterile gloves is described in Procedure 44-3 at the end of this chapter.

Remember, once you are wearing sterile gloves, you may touch only the items in the sterile field. So you must remove any drape covering the sterile instrument tray before you glove. Sterile gloves provide a small margin of safety in preventing contamination; your movements must be controlled and precise to work within this margin to protect the sterile area.

Sanitizing, Disinfecting, and Sterilizing Equipment

Many supplies used in a doctor's office are disposable. Many surgical instruments, however, are made of steel and are reusable. Preparing surgical instruments for reuse involves

cleaning them with germicidal soap and water (a process called *sanitization*), then disinfecting and/or sterilizing them, depending on how the equipment will be used. These procedures are described more fully in the *Examination and Treatment Areas* and *Infection Control Practices* chapters.

► Preoperative Procedures

LO 44.5

You must complete a number of steps before a surgical procedure, including performing various preliminary duties, preparing the surgical room, and physically preparing the patient for surgery.

Preliminary Duties

The first tasks you will perform before the surgery include providing **preoperative** (prior to surgery, or “pre-op”) instructions to the patient, completing various administrative tasks, and easing the patient's fears.

Preoperative Instructions When a patient is scheduled for a minor surgical procedure in the doctor's office, you must explain the preoperative instructions. Be prepared to answer the patient's questions about the procedure and possible risks. The patient may ask you, rather than the doctor, such questions or may need clarification of information provided by the doctor.

A patient may need to follow certain dietary and fluid restrictions before a minor surgical procedure. Not eating or drinking for a specific period of time is a common restriction. The patient's medications may also be restricted because of anesthetic administration during the procedure. Non-English-speaking patients may need an interpreter who can help them understand the forms they must sign and their instructions.

Instruct the patient to wear either comfortable, loose-fitting clothes that will not interfere with the procedure or clothing that can be removed easily. In most cases, patients also need to arrange for someone to drive them home and stay with them for 24 hours after the procedure.

Administrative and Legal Tasks You must ensure that all the necessary paperwork is completed before surgery. Routine administrative tasks include completing the required insurance forms and obtaining prior authorization from the patient's insurance company.

Make absolutely certain the patient reads, understands, and signs the surgical consent form. The patient needs a clear understanding of what to expect during and after the surgery to give informed consent as required by law. Sometimes surgery is performed on a child or a patient with limited understanding of legal documents. In such cases, the consent form must be signed by the patient's parent or legal guardian.

Failure to obtain the necessary paperwork prior to a surgical procedure can cause serious legal problems. The doctor and other staff members could be held legally liable if problems were to develop during or after the procedure.

It is common practice to call the patient the day before the surgery to confirm the appointment. This call also provides a chance to ensure that the patient follows the preoperative instructions. You may be responsible for making this call.

Easing the Patient's Fears Knowing what to expect during and after a surgical procedure will ease the patient's fears. This information allows him or her to plan daily activities and, if necessary, to arrange for help at home during the recovery period.

Some offices have educational materials such as brochures, fact sheets, or videos about the procedure the patient will undergo. You may assist in preparing or acquiring these materials if your office's policy includes such participation for medical assistants. This type of information may increase patient compliance with pre- and postoperative instructions.

Much of a patient's fear about a surgical procedure can be overcome if you spend sufficient time before the procedure explaining what to expect. Be prepared to answer the patient's questions honestly, calmly, and confidently. Your calm and knowledgeable manner will reassure the patient. If the answer to a question requires experience or knowledge beyond your own, pass the question on to the healthcare practitioner.

Preparing the Surgical Room

Prior to surgery, the doctor should inform you of specific instructions concerning patient preparation. He also will tell you what special equipment or supplies are necessary for the procedure.

Because patients are likely to feel anxious before a procedure, it is best to have everything ready in the surgical room before you escort the patient into the room. Make sure the room is clean, neat, and free of waste from previous procedures. The examining table should have been cleaned and disinfected, and surface barriers (table paper and pillow covers) should have been changed.

Check to see that there is adequate lighting. Make sure that all equipment and supplies necessary for the procedure are available. Check the date and sterilization indicator on sterilized packs and supplies.

You will then wash your hands and prepare the sterile field as outlined in Procedure 44-1 at the end of this chapter. The sterile field and the instruments should be draped with a sterile towel.

Preparing the Patient

Just before the surgery, various concerns must be addressed and procedures completed in sequence. The initial tasks are followed by gowning and positioning the patient and preparing the patient's skin for surgery.

Initial Tasks Before leading the patient into the surgical room, give the patient an opportunity to use the bathroom. You must also find out whether she has followed the presurgical instructions. Restrictions on food and fluid intake are of particular concern. Also, ask what medications the patient is taking and whether she has taken that day's dosage.

Measure the patient's vital signs. Ask if there are any symptoms or problems the doctor should know about before the surgery. If any unusual signs or symptoms are present, notify the doctor. The doctor will want to examine the patient before proceeding.

Check the chart for medication orders, such as pain medication or a tranquilizer to calm the patient. Medications

should be administered at this time so that they can take effect before surgery.

Gowning and Positioning the Patient Some procedures require the patient to disrobe and put on a gown to expose the surgical site. If this is the case, you should offer to assist, if appropriate, or leave the room while the patient changes. You should then help the patient onto the table and into the position required for the procedure. You may use one or more small pillows to make the patient as comfortable as possible. Then adequately drape the patient to retain body heat and preserve personal dignity.

Sterile drapes are also used to create a sterile field on a patient's body around the surgical site. Drapes come in a variety of sizes and styles. A fenestrated drape has a round or slit-like opening cut out in the center to provide access to the surgical site.

Surgical Skin Preparation Prior to surgery, the patient's skin must be prepared to reduce the number of microorganisms and the risk of surgical site infection. Preparation includes cleaning the area, removing the hair, and applying antiseptic. The area prepared should be 2 inches larger than the intended surgical field. The surgical field is the area exposed in the center of the fenestrated drape. The extra prepared skin area allows for draping without contaminating the surgical field.

Cleaning the Area Before proceeding with the surgical skin preparation, wash your hands and don exam gloves. Place a plastic-backed drape under the surgical site to absorb any liquids. Clean the site first with an iodine-based solution, using forceps and gauze sponges dipped in the solution. Begin at the center of the surgical site and work outward in a firm, circular motion (Figure 44-11). Discard the gauze sponge after each complete pass. Clean in concentric circles until you cover the full preparation area. Continue the process, repeating as

FIGURE 44-11 Clean the surgical site with an iodine-based solution. Begin at the center of the surgical site and work outward in a firm, circular motion. Clean in a circular, outward pattern 2 inches larger than the surgical field.

necessary, for at least 2 minutes or the amount of time specified in the office's procedure manual. Cleaning takes more time if a wound is dirty or contains foreign materials. When procedures are performed on a hand or foot, clean the entire hand or foot. The skin and body openings, particularly the nose, mouth, and perineum, cannot be considered sterile. Nevertheless, the principles of aseptic technique require that you try to keep the area as contamination-free as possible.

Removing Hair from the Area Depending on office policy, you may be required to remove hair from the surgical site. Shaving often causes many small wounds on the skin, which increases the risk of infection, and is not recommended. Some experts feel that hair should not be removed unless it is thick enough to interfere with surgery. If this is the case, hair may be trimmed with scissors or electric trimmers or smoothed out of the way. This should be done with care—to avoid damaging the skin—immediately before surgery.

Applying the Antiseptic Antiseptics are agents applied to the skin to limit the growth of microorganisms and to help prevent infection. Povidone iodine (Betadine®) is most commonly used, but chlorhexidine gluconate (Hibiclens®) or benzalkonium chloride (Zephiran®) may also be used, particularly if the patient is allergic to iodine. After cleaning or removing the hair when needed, swab an area 2 inches larger than the surgical field with the antiseptic solution in a circular, outward motion, starting at the surgical site. This is the same motion used for cleaning the surgical site. For surgery on a hand or foot, swab the entire hand or foot. Allow the antiseptic to air-dry; do not pat it dry—that would remove some of the solution's antiseptic properties.

When the area is dry, treat it as a sterile field. Instruct the patient not to touch the area. Cover the area with a sterile fenestrated drape, from front to back. Avoid reaching over the field. At this point, notify the physician that the patient is ready. Then prepare yourself to assist with the surgery.

▶ Intraoperative Procedures

LO 44.6

Intraoperative procedures are procedures that take place during surgery. You may be asked to perform a wide variety of unsterile and sterile tasks during surgery, such as preparing a local anesthetic, monitoring the patient, processing specimens, and handing instruments to the doctor. The doctor also may ask you to explain to the patient step by step what will be done next during the procedure.

Administering a Local Anesthetic

Before beginning the surgical procedure, the physician will administer a local anesthetic. Some local anesthetics are injected. An injected anesthetic is packaged in a sterile vial (a small glass bottle with a self-sealing rubber stopper). Other local anesthetics come in a cream, gel, or spray form. These anesthetics are topical (applied directly to the skin) and affect only the area to which they are applied. The choice of administration method depends on how invasive or painful the procedure is likely to be.

Lidocaine (Xylocaine®) is the most commonly used anesthetic, used as an injectable or a topical gel anesthetic.

Tetracaine hydrochloride (Pontocaine®), a long-acting anesthetic, is injected or topical.

Topical Application A topical anesthetic is useful when the pain will be mild or when only the skin's upper layers are affected. It is common to use such agents to anesthetize the area of a small laceration prior to suturing. Sometimes an anesthetic cream is applied before a local anesthetic is injected to reduce or eliminate the pain caused by the injection. A topical anesthetic must usually remain on the skin for 10 to 15 minutes for the area to become sufficiently anesthetized.

Injections If a local anesthetic is to be injected, it is typically administered after the skin is prepared but before the patient is draped. In some cases, however, the anesthetic is injected prior to skin preparation to allow time for it to take effect. In either case, it is important to note the time of anesthetic administration in the patient's chart.

If the doctor is already wearing sterile gloves, you may be asked to assist in administering the anesthetic. Because administering an anesthetic is an unsterile task (the outside of the vial is unsterile), when performing it, follow proper procedure to protect the sterility of the doctor's gloves and the anesthetic solution.

First, check the label of the anesthetic vial two times to confirm that it is the correct solution. Then, clean the vial's rubber stopper with a 70% isopropyl alcohol solution and leave the alcohol pad on top of the stopper. Present the requested needle and syringe to the doctor by peeling half the outer wrapper away and allowing the doctor to remove them from the wrapper.

Remove the pad from the rubber stopper and hold the vial so that the doctor can verify it is the proper medication. Turn the vial upside down and hold it securely around the base, without touching the sterile stopper. Be sure to hold the vial in front of you at shoulder height. Because significant force will be necessary to push the needle through the rubber stopper, brace the wrist of the hand holding the vial with your free hand. Hold the vial firmly so that the doctor can withdraw the anesthetic from it (Figure 44-12). Check the vial a third time to confirm that it is the correct solution.

FIGURE 44-12 You must hold the anesthetic vial firmly to allow the physician to puncture the rubber stopper with the needle.

© Cliff Moore

Potential Side Effects of the Anesthetic Patients sometimes have reactions to anesthetic medications and should be informed of this prior to the procedure. Although rare, reactions may include dizziness, loss of consciousness, seizures, or cardiac arrest. Adverse reactions can occur if the anesthetic dose is too high or if it is absorbed too quickly. Reactions can also occur if the patient is taking other medications that should not be mixed with the anesthetic. All medications (including over-the-counter medications) that a patient is taking at the time of surgery must be documented to avoid possible reactions.

Use of Epinephrine Epinephrine is a sterile solution that is sometimes injected along with an anesthetic. It constricts the blood vessels, making them narrower, which reduces bleeding and prolongs the action of the local anesthetic. Epinephrine is used if the surgery site is an area with many small blood vessels that are expected to bleed profusely (such as the head). Reducing bleeding makes it easier to see and to repair the wound.

Epinephrine should be used with caution, however, in patients with heart disease or respiratory disease. Epinephrine also prolongs the anesthesia because epinephrine slows the rate at which the anesthetic spreads into the tissue. This effect may or may not be desirable. There is some concern that epinephrine may increase wound infection rates. If the wound is highly contaminated, the physician may choose to use anesthetic without epinephrine.

Assisting the Physician During Surgery

Your role in surgical assisting depends on the type of surgery and the physician's preference. You may assist the physician in one of two capacities with different duties: as a floater—an unsterile assistant who is free to move about the room and attend to unsterile needs—or as a sterile scrub assistant—who assists in handling sterile equipment during the procedure.

The Floater If you are assisting as a floater (sometimes called a circulator), you will perform a routine handwash and don exam gloves. Remember, you cannot touch sterile items in the sterile field because you have not performed a surgical scrub and are not wearing sterile gloves. Procedure 44-4, at the end of this chapter, outlines the tasks performed by a floater (unsterile assistant).

Monitoring and Recording One of a floater's most important duties is to monitor the patient during the procedure. You must measure vital signs regularly and observe the patient for reactions to the anesthetic. Record all observations in the patient's chart. Also, write down any information or notes the doctor requests. You must keep a record of time, including when the anesthetic is administered, when the procedure begins, and when the procedure is completed.

Processing Specimens When you serve as a floater during surgery, the doctor may ask you to receive and process specimens for laboratory examination. Most tissues are placed in a 10% formalin solution to preserve them before they are sent to the laboratory. If the container is not prefilled,

half-fill the specimen container with the formalin solution ahead of time. Remove the lid of the specimen container without touching the rim. Hold the container out toward the doctor so that she can place the tissue directly into it without contaminating the sample (Figure 44-13).

The container should be labeled with the following information:

- The patient's name and the doctor's name
- The date and time of collection
- The body site from which the specimen was obtained
- Your initials

If more than one specimen is obtained from a patient, place each specimen in a separate container. Label each container with the necessary information, along with a number to indicate the order in which the specimens are obtained (no. 1, no. 2, and so on). The physician will usually tell you the exact location of each specimen taken. You will also fill out a laboratory requisition slip to send along with the specimen(s). Specimen containers should be placed in a special transport bag labeled with the biohazard symbol. Most transport bags have an outside pouch for the lab requisition form. The form should accompany the sample but not be placed in contact with the specimen container. This protects lab personnel when they handle the requisition form.

Other Duties As a floater, you also may be asked to perform a number of other duties, including:

- Assisting with the injection of additional anesthetic
- Adding additional sterile items to the sterile tray
- Pouring sterile solutions
- Keeping the surgical area clean and neat during the procedure
- Repositioning the patient as necessary
- Adjusting lighting

FIGURE 44-13 Be sure to hold the specimen container so that the doctor can place the tissue in it without touching the rim or outside of the container with the tissue.

© McGraw-Hill Education/David Moyer/photographer

The Sterile Scrub Assistant When serving as a sterile scrub assistant, you must perform a surgical scrub and wear sterile gloves. You may be asked to perform a variety of tasks under sterile conditions. Follow the rules of sterile technique listed earlier in this chapter, and remember not to touch unsterile items after putting on sterile gloves. Procedure 44-5, at the end of this chapter, and the sections that follow outline the tasks performed by a sterile scrub assistant.

Handling Instruments Your first duty as a sterile scrub assistant is, typically, to close the instruments on the sterile tray because they are left in the open position during sterilization. Your next duty is to rearrange the instruments on the tray in the order in which they will be used or according to the doctor's preference. Instruments are generally used in the following sequence:

- Cutting instruments
- Grasping instruments
- Retractors
- Probes
- Suture materials
- Needle holders and scissors

Prepare for swabbing by placing several sterile gauze squares in the dressing forceps, to be ready when needed. As the sterile scrub assistant, you will be asked to pass instruments to the doctor during the procedure. You must hold instruments so that the doctor can grasp them safely and securely, without needing to reposition them in her hands. At the same time, the instruments must be handled properly to maintain their sterility.

When passing scissors and clamps, hold them by the hinge (Figure 44-14). You will have a clear view of the instrument's tip and the doctor will have full use of the handles. Firmly slap the instrument handles into the doctor's extended palm. The doctor's hand will close around the handles as a reflex action to the slapping. This technique reduces the risk of dropping an instrument. If the scissors or clamp is curved, the curve should follow the same curve as the doctor's hand.

FIGURE 44-14 Holding the scissors by the hinge, slap the handles into the doctor's hand.

© MIXA/Getty Images RF

When passing a scalpel, hold it above and just behind the cutting edge of the blade with the blade facing away from your palm so that the doctor can grasp the entire handle (Figure 44-15). You should wait until the doctor has fully grasped the handle before taking your hand away. The doctor will wait until your hand is fully out of the way before moving the scalpel. This requires good communication between you and the doctor and helps avoid any injury while passing the scalpel. Pass a needle holder with suture material so that the needle is pointing up, and hold the end of the suture material with your other hand to prevent the material from becoming tangled in the handles. You may also use a sterile tray called a passing tray when passing sharp instruments to the doctor. Using a passing tray reduces the likelihood of having an exposure incident while passing instruments (Figure 44-16).

Other Duties As a sterile scrub assistant, you also may be asked to swab fluids from a wound or to retract the edges of a wound to help the doctor view the area. While the doctor is closing the wound, you may be required to cut the suture material after each stitch. The doctor may not verbalize every request to you. With practice and after experience with a particular doctor, you will learn how to respond to the doctor's actions.

FIGURE 44-15 Hold a scalpel above and just behind the cutting edge as you pass the handle into the palm of the doctor's hand.

© Alexey Poprotsky/Shutterstock

FIGURE 44-16 A passing tray may be used to safely pass sharp instruments during a surgical procedure.

When cutting suture materials, leave $\frac{1}{8}$ inch of the material above the knot. This length prevents the suture from coming untied but is short enough that it does not bother the patient.

► Postoperative Procedures

LO 44.7

You will be responsible for the patient's **postoperative** ("post-op") follow-up after the surgical procedure. Your duties may include immediate care of the patient, proper cleaning of the surgical room, and follow-up care of the patient. Procedure 44-6, at the end of this chapter, outlines the tasks performed after a minor surgical procedure.

Immediate Patient Care

Patient care is your top priority as a medical assistant. Except for intravenous medications, you will administer postoperative medications the physician requests for the patient. You also will ensure that the patient remains lying down on the examining table for the prescribed length of time after the procedure. During this period, continue to monitor the patient's vital signs and watch for adverse reactions. Document your observations in the patient's chart.

Dressing the Wound You also may dress the wound during the monitoring period. Dressings are sterile materials used to cover an incision. They serve a number of functions. They protect the wound from further injury and keep the wound clean, thus preventing infection. Dressings also reduce bleeding, absorb fluid drainage, reduce discomfort to the patient, speed healing, and reduce the possibility of scarring. Gauze dressings are the most common type and come in a variety of sizes and shapes.

Before dressing the wound, don clean exam gloves. Place the sterile dressing over the site and secure it appropriately.

Bandaging the Wound It may be necessary to apply a bandage (a clean strip of gauze or elastic material) over the dressing to help hold it in place. Tube gauze may be needed for bandaging wounds on fingers or other extremities. Application of this type of gauze requires an applicator. The applicator is a wire cage on which the gauze is loaded. Bandages also may be used to improve circulation, to provide support or reduce tension on a wound or suture and prevent it from reopening, or to prevent movement of that area of the body. Adhesive tape also may be used for these purposes. Some patients are allergic to the adhesive, but most tapes are now hypoallergenic. The patient is usually more comfortable after a bandage or adhesive tape has been applied.

Postoperative Instructions After the procedure, provide oral postoperative instructions to the patient. You may do this during the monitoring part of the postoperative period or afterward. These instructions include guidelines for pain management and instructions for wound care. Postoperative information also includes dietary or activity restrictions, if any, and when to come in for a follow-up appointment. It is a good idea to ask patients to repeat what you have said so that you know they understand the information.

Instructions should be provided in writing as part of a complete postoperative information packet. You may be asked to help prepare or update packet materials, especially if you routinely assist patients as they recover from minor surgery. A postoperative information packet might include the following information:

- Proper wound care instructions
- Suggestions for pain relief and reduction of swelling, such as medications and hot or cold packs
- Dietary restrictions
- Activity restrictions
- Timing for a follow-up appointment or an appointment card

Wound care instructions include details on changing the dressing, keeping the wound clean, recognizing signs of infection, and protecting the wound. The instructions may vary depending on the depth and size of the wound. In general, the bandage should be removed after the first 24 hours or if it becomes soaked with blood, wet, or dirty. A wet dressing allows bacteria and other contaminants to enter the wound. In most cases, the wound may be cleaned with soap and water after 24 to 48 hours. Once cleaned, gently dry the incision with a sterile gauze and cover with a clean, dry bandage.

You should teach the patient about the signs of infection. For more information, see *Educating the Patient: When to Call the Doctor About a Wound*. Encourage the patient to protect the incision from sun exposure for the first 6 months; doing so helps prevent the incision line from becoming darker than the surrounding skin.

The length of time it takes for a wound to heal varies with the site, the patient's age and health status, and the severity

EDUCATING THE PATIENT

When to Call the Doctor About a Wound

Whether a wound is postsurgical or from an accident, it is important for patients to know when they should call the doctor. Understanding when a wound needs medical attention can reduce the instances of scarring and infection. You can help by teaching them what to look for when they have a wound. Patients with any wounds should call the office if they have any of the following:

- Jagged or gaping edges
- A face wound
- Limited movement in the area of the wound
- Tenderness or inflammation at the wound site
- Purulent drainage
- A fever greater than 100°F
- Red streaks near the wound
- A puncture wound
- Bleeding that does not stop after 10 minutes of pressure
- Sutures coming out on their own or too early

of the wound. So each patient needs specific instructions on how long to continue with the dressings and when to return for suture or staple removal. He or she also may need specific information about limiting activities.

Patient Release Notify the doctor when the patient is stabilized and ready to leave. The doctor may want to further observe and instruct the patient. Be sure to offer assistance if the patient needs help getting dressed.

Then help the patient check out. Schedule the next appointment for the patient. Make sure the patient has the correct discharge packet. Confirm arrangements to transport the patient home. Finally, assist the patient to the car or other transport if this is part of office procedure.

If a patient insists on driving himself home, enter this information on the chart. Indicate the time and have the patient initial the entry. This documentation is important for legal reasons. It would clarify liability, should an accident occur as a result of a reaction to the surgery or the anesthetic.

Go to CONNECT to see a video exercise about
Assisting after Minor Surgical Procedures.

Go to CONNECT to see a video exercise about
Suture Removal.

Surgical Room Cleanup

If there is time during the monitoring period, begin to clean up the surgical area. If time is not available then, perform the cleanup routine after the patient has been released. Refer to the *Examination and Treatment Areas* chapter for sanitization and disinfection guidelines.

Follow-Up Care

During a follow-up appointment, the physician examines the patient's surgical wound. The healthcare practitioner may ask you to change the dressing or remove the wound closures. Typically, suture or staple removal takes place 5 to 10 days after minor surgery. The sutures or staples are ready for removal when a clean, unbroken suture line is observed. There should be no scabs, no seepage from the wound, and no visible opening. Any of these signs may indicate unhealed areas. Suture removal is described in Procedure 44-7, at the end of this chapter. Staple removal is similar, except that staple removal forceps, rather than thumb forceps and scissors, are used to remove the staples.

PROCEDURE 44-1 Creating a Sterile Field

Procedure Goal: To create a sterile field for a minor surgical procedure

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Tray or Mayo stand, sterile instrument pack, sterile transfer forceps, cleaning solution, sterile drape, and additional packaged sterile items as required

Method:

1. Clean and disinfect the tray or Mayo stand.
2. Wash your hands and assemble the necessary materials.
3. Check the label on the instrument pack to make sure it is the correct pack for the procedure.
4. Check the date and sterilization indicator on the instrument pack to make sure the pack is still sterile.

RATIONALE: *Using an out-of-date pack puts the patient at risk for surgical site infection.*

5. Place the sterile pack on the tray or stand and unfold the outermost fold away from yourself.
6. Unfold the sides of the pack outward, touching only the areas that will become the underside of the sterile field.

RATIONALE: *Touching the inside of the pack will contaminate the sterile field.*

7. Open the final flap toward yourself, stepping back and away from the sterile field.

FIGURE Procedure 44-1 Step 7 Open the flap toward yourself last to avoid reaching over the sterile field.

© McGraw-Hill Education

8. Place additional packaged sterile items on the sterile field.
 - Ensure that you have the correct item or instrument and that the package is still sterile.
 - Stand away from the sterile field.
 - Grasp the package flaps and pull apart about halfway.
 - Bring the corners of the wrapping beneath the package, paying attention not to contaminate the inner package or item.
 - Hold the package over the sterile field with the opening down; with a quick movement, pull the flap completely open and snap the sterile item onto the field.

FIGURE Procedure 44-1 Step 8 Hold the package over the sterile field with the opening down. Pulling the flap open, snap the instrument onto the field.

© McGraw-Hill Education

FIGURE Procedure 44-1 Step 9 Placing the bowl at the edge of the sterile field keeps you from reaching over the sterile field when you pour liquids into the bowl.

© McGraw-Hill Education

9. Place basins and bowls near the edge of the sterile field so that you can pour liquids without reaching over the field.

RATIONALE: *Reaching over the field may drop contaminants into the field.*

10. Use sterile transfer forceps if necessary to add additional items to the sterile field.
11. If necessary, don sterile gloves after a sterile scrub to arrange items on the sterile field.

PROCEDURE 44-2 Performing a Surgical Scrub

Procedure Goal: To remove dirt and microorganisms from under the fingernails and from the surface of the skin, hair follicles, and oil glands of the hands and forearms

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Dispenser with surgical soap, sterile surgical scrub brush or sponge, and sterile towels

Method:

1. Remove all jewelry and roll up your sleeves to above the elbow.
2. Assemble the necessary materials.
3. Turn on the faucet using the foot or knee pedal.
4. Wet your hands from fingertips to elbows, keeping your hands higher than your elbows.

RATIONALE: *This prevents water from running down your arms and contaminating the washed area.*

5. Under running water, use a sterile brush to clean under your fingernails.
6. Apply surgical soap and scrub your hands, fingers, areas between the fingers, wrists, and forearms with the scrub sponge, using a firm, circular motion. Follow the manufacturer's recommendations to determine appropriate length of time (usually 2 to 6 minutes).

RATIONALE: *Scrubbing all surfaces dislodges microorganisms so that they can be rinsed away.*

FIGURE Procedure 44-2 Step 6 With a sterile scrub brush, use a circular motion to scrub every surface of your hands and forearms.

© McGraw-Hill Education

7. Rinse from fingers to elbows, always keeping your hands higher than your elbows.

FIGURE Procedure 44-2 Step 7 Keep your hands higher than your elbows when rinsing after a surgical scrub so that water runs away from the fingertips.

© McGraw-Hill Education

8. Thoroughly dry your hands and forearms with sterile towels, working from the hands to the elbows.
RATIONALE: *Using sterile towels prevents recontaminating your hands.*
9. Turn off the faucet with the foot or knee pedal. Use a sterile paper towel if a foot or knee pedal is not available.

FIGURE Procedure 44-2 Step 8 Dry your hands with sterile towels, working from the hands to the elbows.

© McGraw-Hill Education

PROCEDURE 44-3 Donning Sterile Gloves

Procedure Goal: To don sterile gloves without compromising the sterility of the gloves' outer surface

OSHA Guidelines: This procedure does not involve exposure to blood, body fluids, or tissues.

Materials: Correctly sized, prepackaged, double-wrapped sterile gloves

Method:

1. Obtain the correct size gloves.
2. Check the package for tears and ensure that the expiration date has not passed.
RATIONALE: *A torn package should be considered unsterile.*
3. Perform a surgical scrub.
4. Peel the outer wrap from the gloves and place the inner wrapper on a clean surface above waist level.

FIGURE Procedure 44-3 Step 4 Place the inner wrap on a clean surface, above waist level, with the cuff end closest to your body.

© McGraw-Hill Education

7. Use instructions provided on the inner package, if available.
8. Do not reach over the sterile inside of the inner package.
9. Follow these steps if there are no instructions:
 - a. Open the package so that the first flap is opened away from you.
 - b. Pinch the corner and pull to one side.
 - c. Put your fingertips under the side flaps and gently pull until the package is completely open.
10. Use your nondominant hand to grasp the inside cuff of the opposite glove (the folded edge). Do not touch the outside of the glove. If you are right-handed, use your left hand to put on the right glove first, and vice versa.
RATIONALE: *Grabbing the inside of the glove allows you to put it on without contaminating its outside.*
11. Holding the glove at arm's length and waist level, insert the dominant hand into the glove, palm facing up. Do not let the outside of the glove touch any other surface.

FIGURE Procedure 44-3 Step 11 When donning the glove, do not let the outside of the glove touch any other surface.

© McGraw-Hill Education

5. Position gloves so that the cuff end is closest to your body.
6. Touch only the flaps as you open the package.
RATIONALE: *Touching the inside of the package could contaminate the gloves.*

12. With your sterile gloved hand, slip the gloved fingers into the cuff of the other glove.
13. Pick up the other glove, touching only the outside. Do not touch any other surfaces.

FIGURE Procedure 44-3 Step 13 Slip the fingers of your gloved hand into the other glove's cuff, touching only the outside.

© McGraw-Hill Education

FIGURE Procedure 44-3 Step 14 Pull the glove up and onto your hand without touching the sterile gloved hand to your skin.

© McGraw-Hill Education

14. Pull the glove up and onto your hand, ensuring that the sterile gloved hand does not touch your skin.
15. Adjust your fingers as necessary, touching only glove to glove.
16. Do not adjust the cuffs because your forearms may contaminate the gloves.
17. Keep your hands in front of you, between your shoulders and waist. If you move your hands out of this area, they are considered contaminated.

18. If contamination or the possibility of contamination occurs, change gloves.
19. Remove these gloves the same way you remove clean gloves, by touching only the inside.

RATIONALE: *Touching only the inside of the gloves reduces exposure to the patient's blood and body fluids.*

PROCEDURE 44-4 Assisting as a Floater (Unsterile Assistant) During Minor Surgical Procedures

WORK // DOC

Procedure Goal: To provide assistance to the doctor during minor surgery while maintaining clean or sterile technique as appropriate

OSHA Guidelines:

Materials: Sterile towel, tray or Mayo stand, appropriate instrument pack(s), needles and syringes, anesthetic, antiseptic, sterile water or normal saline, small sterile bowl, sterile gauze squares or cotton balls, specimen containers half-filled with preservative, suture materials, sterile dressings, tape, patient's chart/progress note, laboratory requisition form

Method:

1. Perform routine handwashing and don exam gloves.
2. Monitor the patient during the procedure; record the results in the patient's chart.
3. During the surgery, assist as needed.
4. Add sterile items to the tray as necessary.

5. Pour sterile solution into a sterile bowl as needed.
6. Assist in administering additional anesthetic.
 - a. Check the medication vial two times.
 - b. Clean the rubber stopper with an alcohol pad (write the date opened when using a new bottle); leave the pad on top.
 - c. Present the needle and syringe to the doctor.
 - d. Remove the alcohol pad from the vial and show the label to the doctor.
 - e. Hold the vial upside down and grasp the lower edge firmly; brace your wrist with your free hand.

RATIONALE: *This firmly supports the vial to sustain the force of the needle being inserted into the rubber stopper.*

 - f. Allow the doctor to fill the syringe.
 - g. Check the medication vial a final time.
7. Receive specimens for laboratory examination.
 - a. Uncap the specimen container; present it to the doctor for the specimen's introduction.
 - b. Replace the cap and label the container.
 - c. Treat all specimens as infectious.
 - d. Place the specimen container in a transport bag or other container.
 - e. Complete the requisition form to send the specimen to the laboratory.

PROCEDURE 44-5 Assisting as a Sterile Scrub Assistant During Minor Surgical Procedures

Procedure Goal:

To provide assistance to the doctor during minor surgery while maintaining clean or sterile technique as appropriate

OSHA Guidelines:

Materials:

Sterile towel, tray or Mayo stand, appropriate instrument pack(s), needles and syringes, anesthetic, antiseptic, sterile water or

normal saline, small sterile bowl, sterile gauze squares or cotton balls, specimen containers half-filled with preservative, suture materials, sterile dressings, and tape

Method:

1. Perform a surgical scrub and don sterile gloves.
(Remember, remove the sterile towel covering the sterile field and instruments before gloving.)
RATIONALE: *You will be handling sterile instruments.*
2. Close and arrange the surgical instruments on the tray.
RATIONALE: *They should be quickly and easily located.*
3. Prepare for swabbing by inserting gauze squares into the sterile dressing forceps.
4. Pass the instruments as necessary.
5. Swab the wound as requested.
6. Retract the wound as requested.
7. Cut the sutures as requested.

PROCEDURE 44-6 Assisting After Minor Surgical Procedures

Procedure Goal: To provide assistance to the doctor during and the patient after minor surgery while maintaining clean or sterile technique as appropriate

OSHA Guidelines:

Materials: Examination gloves, antiseptic, tray or Mayo stand, sterile dressings, and tape

Method:

1. Monitor the patient.
2. Don clean exam gloves and clean the wound with antiseptic.

3. Dress the wound.
RATIONALE: *To protect the wound.*
4. Remove the gloves and wash your hands.
5. Give the patient oral postoperative instructions in addition to the release packet.
RATIONALE: *The patient will need to understand wound care, medication use, and dietary instructions for proper healing.*
6. Discharge the patient.
7. Put on clean exam gloves.
8. Properly dispose of used materials and disposable instruments.
9. Sanitize reusable instruments and prepare them for disinfection and/or sterilization as needed.
10. Clean equipment and the exam room according to OSHA guidelines.
11. Remove the gloves and wash your hands.

Procedure Goal: To remove sutures from a healing wound while maintaining sterile technique and protecting the integrity of the closed wound

OSHA Guidelines:

Materials:

Tray or Mayo stand, patient chart/progress note, suture removal pack (suture scissors and thumb forceps or skin staple remover), sterile towel, antiseptic solution, hydrogen peroxide (3%), two small sterile bowls, sterile gauze squares, sterile strips or butterfly closures, sterile dressings, and tape

Method:

1. Clean and disinfect the tray or Mayo stand.
2. Wash your hands and assemble the necessary materials.
3. Check the date and sterilization indicator on the suture removal pack.
RATIONALE: You must ensure that the pack has been subjected to a sterilization procedure and has not expired.
4. Unwrap the suture removal pack; place it on the tray or stand to create a sterile field.
RATIONALE: You need to maintain a sterile field to avoid contaminating the wound.
5. Unwrap the sterile bowls; add them to the sterile field.
RATIONALE: You need to maintain a sterile field to avoid contaminating the wound.
6. Pour a small amount of antiseptic solution into one bowl and a small amount of hydrogen peroxide into the other bowl.
7. Cover the tray with a sterile towel to protect the sterile field while you are out of the room.
8. Escort the patient to the exam room and explain the procedure.
9. Perform a routine handwash, remove the towel from the tray, and don exam gloves.
10. Remove the old dressing.
 - a. Lift the tape toward the middle of the dressing to avoid pulling on the wound.
 - b. If the dressing adheres to the wound, cover the dressing with gauze squares soaked in hydrogen peroxide. Leave the wet gauze in place for several seconds to loosen the dressing.
 - c. Save the old dressing for the doctor to inspect.
11. Inspect the wound for signs of infection.

12. Clean the wound with gauze pads soaked in antiseptic; pat it dry with clean gauze pads.
13. Remove the gloves and wash your hands.
14. Notify the doctor that the wound is ready for examination.
RATIONALE: The doctor should determine if the sutures should be removed.
15. Once the doctor indicates the wound is sufficiently healed to proceed, don clean exam gloves.
16. Place a square of gauze next to the wound for collecting the sutures or staples as they are removed.
17. Sutures: Grasp the first suture knot with forceps. Staples: Slide the staple remover under the first staple.
18. Sutures: Gently lift the knot away from the skin to allow room for the suture scissors. Staples: Gently press down on the staple remover handle.

FIGURE Procedure 44-7 Step 18 Gently pulling each suture up and away from the skin creates room for the suture scissors.

© McGraw-Hill Education

19. Sutures: Slide the suture scissors under the suture material and cut the suture where it enters the skin.
RATIONALE: This minimizes the amount of exposed suture that travels beneath the skin during removal.
Staples: Continue pressing down on the staple remover to straighten the staple so that it exits the skin.
20. Sutures: Gently lift the knot up and toward the wound to remove the suture without opening the wound.

FIGURE Procedure 44-7 Step 20 Lift the knot up and toward the wound to prevent opening the wound.

© McGraw-Hill Education

Staples: Observe the staple on each side to ensure that it is completely out of the skin.

21. Place the suture or staple on the gauze pad; inspect to ensure that the entire suture or staple is present.

RATIONALE: *Sutures inadvertently left in place may cause an infection.*

FIGURE Procedure 44-7 Step 21 Place sutures on a gauze square so that you can count and inspect them.

© McGraw-Hill Education

22. Repeat the removal process until all sutures or staples have been removed.

23. Count the sutures or staples and compare the number with that indicated in the patient's record.
24. Clean the wound with antiseptic; allow it to air-dry.
25. Dress the wound as ordered, or notify the doctor if sterile strips or butterfly closures are to be applied.
26. Observe the patient for signs of distress, such as wincing or grimacing.
27. Properly dispose of used materials and disposable instruments.
28. Remove the gloves and wash your hands.
29. Instruct the patient on wound care.
30. In the patient's chart, record pertinent information, such as the condition of the wound and the type of closures used, if any.
31. Escort the patient to the checkout area.
32. Don clean gloves.
33. Sanitize reusable instruments; prepare them for disinfection and/or sterilization as needed.
34. Clean the equipment and exam room according to OSHA guidelines.
35. Remove the gloves and wash your hands.

S U M M A R Y O F L E A R N I N G O U T C O M E S	
LEARNING OUTCOMES	KEY POINTS
44.1 Define the medical assistant's role in minor surgical procedures.	The medical assistant's role in minor surgery includes both administrative and clinical tasks. These include but are not limited to completing insurance forms, obtaining signed patient consent, preparing the surgical room, and assisting during a procedure.
44.2 Describe surgical procedures performed in an office setting.	Several surgical procedures are performed in an office setting, including laser surgery, cryosurgery, and electrocauterization.
44.3 Identify the instruments used in minor surgery and describe their functions.	Various categories of instruments are used in minor surgery, including instruments for cutting and dissecting, grasping and clamping, retracting, dilating and probing, suturing, injecting, withdrawing fluids, and obtaining specimens.
44.4 Describe the procedures for medical and sterile asepsis in minor surgery.	Medical asepsis involves reducing the number of microorganisms to prevent the spread of disease. The goal of surgical asepsis is to eliminate all microorganisms.
44.5 Summarize the medical assistant's duties in preoperative procedures.	A medical assistant's preoperative duties include providing preoperative instructions to the patient, ensuring that all necessary paperwork is completed, easing the patient's fears, and preparing the surgical room.
44.6 Describe the medical assistant's duties during an operative procedure.	A medical assistant may serve in one of two capacities during a surgical procedure: either as an unsterile assistant known as a floater or as a sterile scrub assistant.
44.7 Implement the medical assistant's duties in the postoperative period.	A medical assistant's postoperative duties include giving immediate patient care, dressing and bandaging the wound, giving postoperative instructions, assisting with patient release, and cleaning the surgical room.

CASE STUDY CRITICAL THINKING

© Image Source/Getty Images RF

Recall Peter Smith from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. What is the medical assistant's role during this minor surgical procedure?
2. Why is it important to document the number of sutures Dr. Buckwalter uses to close Mr. Smith's wound?
3. How should you answer Mr. Smith's question about his trip to the Bahamas?
4. Knowing that Mr. Smith started swimming last week, what should you tell him about protecting his sutures?

EXAM PREPARATION QUESTIONS

1. (LO 44.2) The removal of dead tissue from a wound is known as
 - a. Incision
 - b. Debridement
 - c. Ligature
 - d. Cauterization
 - e. Approximation
2. (LO 44.3) An instrument used to clear a blockage is a
 - a. Probe
 - b. Scalpel
 - c. Retractor
 - d. Syringe
 - e. Forceps
3. (LO 44.4) Why is it important to keep your hands higher than your elbows when performing a surgical scrub?
 - a. To avoid touching the sink
 - b. So that the soap reaches the elbows
 - c. To prevent water from contaminating the washed area
 - d. It is not important to keep the hands higher than the elbows
 - e. Your hands should be lower than your elbows
4. (LO 44.2) Another name for a mole is a
 - a. Wart
 - b. Hemangioma
 - c. Ligature
 - d. Birthmark
 - e. Nevus
5. (LO 44.3) Which of the following is the suture with the smallest diameter?
 - a. 2
 - b. 2-0
 - c. 3
 - d. 3-0
 - e. 4-0
6. (LO 44.2) A jagged, open wound of the skin is a(n)
 - a. Incision
 - b. Avulsion
 - c. Laceration
 - d. Puncture
 - e. Abrasion
7. (LO 44.4) When adding solutions to a sterile field, you should cover the label with your palm to keep it
 - a. Sterile
 - b. Dry
 - c. From pouring too quickly
 - d. From dripping
 - e. Visible
8. (LO 44.5) A medical assistant is working in the preoperative area. Which of the following duties would he most likely perform?
 - a. Prepare the surgical room
 - b. Perform a surgical scrub
 - c. Clean the surgical room
 - d. Work as a floater
 - e. Work as a surgical scrub assistant
9. (LO 44.7) Sterile materials used to cover an incision are
 - a. Bandages
 - b. Sterile strips
 - c. Sutures
 - d. Drapes
 - e. Dressings
10. (LO 44.3) What type of instrument is a curette?
 - a. Probing and dilating
 - b. Cutting and dissecting
 - c. Grasping
 - d. Retracting
 - e. Clamping

S O F T S K I L L S S U C C E S S

You are assisting Dr. Sanford with a mole removal. You have already set up the surgical tray and are handing Dr. Sanford her sterile gloves. She tells you that she prefers a no. 11 scalpel blade for this procedure. You know you set up the tray with a no. 10 scalpel blade. How should you respond to Dr. Sanford, and what action should you take?

Orientation to the Lab

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Sylvia Gonzales	9/1/19XX	PCN
PATIENT INFORMATION	Attending	MRN	Other Information
	Alexis N. Whalen, MD	341-73-792	Last Hemoglobin A1C 6.3%

Sylvia Gonzales, a 51-year-old female, is at the office for a 3-month return check for her newly diagnosed Type 2 diabetes. She states that she has taken the medication she received for her “sugar” and she knows the doctor wants to do a special “sugar test” this time. Her medication list includes Januvia® 100 mg daily.

© McGraw-Hill Education

The physician has ordered a fasting blood sugar (FBS) and a hemoglobin A1C blood test. You will need to perform both of these waived tests in your office lab.

Keep Sylvia in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 45, you will be able to:

- 45.1** Describe the purpose of the physician’s office laboratory.
- 45.2** Identify the medical assistant’s duties in the physician’s office laboratory.
- 45.3** Identify important pieces of laboratory equipment.
- 45.4** Illustrate measures to prevent accidents.
- 45.5** Explain the goal of a quality assurance program in a physician’s office laboratory.
- 45.6** Carry out communication with patients regarding test preparation and follow-up.
- 45.7** Carry out accurate documentation, including all logs related to quality control.

- I.C.10** Identify CLIA waived tests associated with common diseases
- I.C.12** Identify quality assurance practices in healthcare
- I.P.10** Perform a quality control measure
- III.C.5** Define the principles of standard precautions
- IV.A.3** Use appropriate body language and other nonverbal skills in communicating with patients, family and staff
- X.P.7** Complete an incident report related to an error in patient care

3. Medical Terminology

- c. Apply various medical terms for each specialty
- d. Define and use medical abbreviations when appropriate and acceptable

4. Medical Law and Ethics

- a. Follow documentation guidelines

9. Clinical Procedures

- a. Practice standard precautions and perform disinfection/sterilization techniques

10. Medical Laboratory Procedures

- a. Practice quality control
- b. Perform selected CLIA-waived tests that assist with diagnosis and treatment
 - (6) Kit testing
 - c. Dip sticks
 - d. Dispose of biohazardous materials
- c. Dispose of biohazardous materials

► Introduction

Laboratory testing of patients' specimens is an integral component of patient care. Medical assistants often perform a role in the clinical laboratory setting in the physician's office. This chapter will introduce you to the various types and uses of common laboratory equipment. You will learn about safety in the laboratory and steps to aid in preventing accidents. A discussion of the Clinical Laboratory Improvement Amendments of 1988 (CLIA '88) and this law's impact on the laboratory setting is included in this chapter to help you understand quality assurance, quality control procedures, and required recordkeeping.

► The Role of Laboratory Testing in Patient Care

LO 45.1

Laboratory analysis of blood, urine, or other body fluids and substances provides three kinds of information about a patient. First, regular monitoring through laboratory tests, like those that are part of an annual exam, can help a physician identify possible diseases or other problems. Second, specific tests can help confirm or contradict a physician's initial diagnosis. Third, laboratory testing can help a physician determine and monitor the proper dosage of a patient's medication.

Kinds of Laboratories

Some physicians prefer to have all laboratory tests performed by a **reference laboratory**, a laboratory owned and operated by an organization outside the practice. Other physicians choose to have some tests completed by the reference

laboratory and some completed in the office in the **physician's office laboratory (POL)**.

Each method of managing laboratory analyses has advantages and disadvantages. Reference laboratories often have more technological resources than those available in the POL. A reference laboratory offers a complete range of tests in all specialties, and subspecialties, including:

- Cytology—microscopic examination of cells to make a diagnosis; Pap smears (tests for detecting cervical cancer) are evaluated in the cytology department.
- Toxicology—testing to identify poisons or other chemicals in the body; workplace drug testing is a type of toxicology test.
- Immunology—testing to identify disorder and disease of the immune system; tests for autoimmune diseases are performed in the immunology department.
- Blood banking—the laboratory department responsible for processing and storing blood and blood products for transfusion and blood disorder treatments; this department would provide blood to someone with severe anemia who needs a transfusion.
- Urinalysis—testing urine for kidney diseases and disorders and certain metabolic disorders; testing for glucose in the urine (a test done on people with diabetes) is part of a urinalysis.
- Histology—microscopic evaluation of tissues to make a diagnosis; a biopsy of a skin lesion is sent to the histology department to examine the tissue for signs of cancer.
- Serology—testing the liquid part of the blood for antibodies against specific microorganisms; testing for malaria and viral hepatitis are serologic tests.

- **Chemistry**—testing for certain substances in the blood, urine, or other body fluids; substances tested for include cholesterol, electrolytes, glucose, calcium, and potassium; a lipid panel for cholesterol and triglycerides is a blood chemistry test.
- **Microbiology**—testing for the presence of pathogenic microorganisms such as bacteria, viruses, fungi, protozoans, and parasites in blood, urine, sputum, reproductive fluids, and fluids from wounds; a nasal culture for MRSA is a microbiology test.
- **Hematology**—testing of blood to identify problems with count, size, or number of blood cells to diagnose diseases and disorders; testing for anemia and leukemia are hematology tests.

Using a reference laboratory frees a physician's staff from testing duties and allows more time for patient care. It also reduces or eliminates the cost of running an in-house lab. Furthermore, some managed care companies have contracts with laboratory companies that require their subscribers to use a specific reference laboratory. An advantage of a POL is that processing tests produces a quicker turnaround and eliminates the need for the patient to travel to other test locations.

The Purpose of the Physician's Office Laboratory

Office policy determines which tests, if any, will be performed at your location and which tests will be performed by a reference laboratory. A POL, like the one shown in Figure 45-1, is responsible for accurate and timely processing of routine tests and for reporting test results to the physician. Tests most often performed in the POL include chemical analyses, hematologic tests, microbiologic tests, and urinalysis (discussed earlier in the chapter).

► The Medical Assistant's Role LO 45.2

As a medical assistant, you may be responsible for processing tests done in the POL, including preparing the patient for the test, collecting the sample, completing the test, reporting the results to the physician, and communicating information about the test from the physician to the patient. Your role in the POL requires you to integrate a great deal of information to serve both the physician and the patient effectively. You will need to master the following subjects:

- Use of laboratory equipment
- Regulations governing laboratory practices and procedures
- Precautions for accident prevention
- Waste disposal requirements
- Housekeeping and maintenance routines
- Quality assurance and control procedures
- Technical aspects of specimen collection and test processing, including expected results
- Communication with patients
- Reporting of test results to the physician
- Recordkeeping of test specimens, procedures, and results
- Inventory and ordering of equipment and supplies

FIGURE 45-1 A physician's office laboratory (POL) may be simple or elaborate, depending on the tests the office performs.

- Use of reference materials in the POL
- Screening and follow-up of test results

► Use of Laboratory Equipment LO 45.3

As a medical assistant, you must be familiar with the operation of common laboratory equipment. Learning to use a specific piece of equipment may take the form of on-the-job training or attending training programs conducted by manufacturers' representatives. You may routinely use the following equipment:

- Autoclave
- Centrifuge
- Microscope
- Electronic equipment and software
- Equipment used for measurement

Autoclave

A steam autoclave is used to sterilize, or eradicate, all organisms on the surfaces of instruments and equipment before they are used on a patient or in testing procedures. Use of the autoclave is discussed in the *Infection Control Practices* chapter.

Centrifuge

A **centrifuge** is a device for spinning a specimen at high speed until it separates into its component parts. The centrifuge in a

POL is generally used to separate whole blood samples into blood components or to prepare urine samples for examination. Use of a centrifuge is described in greater detail in the *Collecting, Processing, and Testing Urine and Stool Specimens* chapter.

Microscope

An instrument often used in a POL is the microscope, commonly used for the examination of blood smears and identification of microorganisms in body fluid samples. Although on-site blood smear evaluation is convenient and fast for both patient and physician, it is important to know which procedures are routinely covered. Only CLIA-approved microscopy procedures are eligible for payment by Medicare and Medicaid. Table 45-1 lists CLIA-approved provider-performed microscopy procedures.

The **optical microscope**, also called the light microscope, is the type most often found in the POL (Figure 45-2). With this type of microscope, light is concentrated (condensed) through a condenser and then focused through the object being examined. This produces an image of the object. **Compound microscopes** use two lenses to magnify the image. The effect of the two lenses is compounded—added together—giving greater magnification than one lens can provide. Compound microscopes are the most common type of optical microscope used in the medical office.

You must be able to operate an optical microscope correctly. First, you need to become familiar with the component parts, described in the following paragraphs.

Oculars The **oculars** are the eyepieces through which you view the image. A microscope is either monocular, with a single eyepiece, or binocular, with two eyepieces. You can adjust the oculars on a binocular microscope to compensate for differences in visual acuity between your right and left eyes. You also can adjust the distance between oculars to match the distance between your eyes. The ocular contains a magnifying lens—called a **10× lens**—that usually magnifies an image 10 times.

Objectives Just below the ocular or oculars, the **objectives** are mounted on a swivel or rotating base called the **nosepiece**. These are known as objectives because they are closest to the

FIGURE 45-2 The microscope is an often used piece of equipment in a POL.

object being magnified. An objective contains another magnifying lens. Generally, microscopes used in the POL have a three-piece objective system with three different magnifications. An objective is moved into position directly under the ocular by rotating the nosepiece.

Two of the objectives are dry objectives; this means there is air space between the specimen under examination and the objective. Condensed (concentrated) light passes through the specimen and the air space above the specimen and then travels toward the objective lens. These dry objectives are low- and high-power lenses, usually 10× and 40×, respectively. When the low-power objective lens is combined with the ocular lenses, the total magnification factor is 100× (10× times 10×). The high-power lens and ocular lenses yield a magnification factor of 400× (10× times 40×).

The third objective is an **oil-immersion objective**, which is used for specimens that need extreme magnification, such as blood smears and bacteriologic slides. It is designed to be lowered into a drop of immersion oil placed directly on the slide above the prepared specimen under examination. This design eliminates the air space between the microscope slide and the objective, where some of the light scatters beyond the objective. Placing the end of the objective in oil reduces the loss of light by creating a column of oil that tightly focuses the light, keeping it from scattering. This results in a much sharper, brighter image, allowing for greater magnification. An oil-immersion objective has a magnification factor of 100×. Combined with the ocular lenses, the total magnification factor is 1,000×.

Arm and Focus Controls The ocular(s) and objectives, collectively referred to as the body tube, are attached to the

TABLE 45-1 CLIA-Approved Provider-Performed Microscopy Procedures

Wet mounts—vaginal, cervical, or skin specimens
Potassium hydroxide preparations
Pinworm examinations
Fern test (for the presence of amniotic fluid in vaginal secretions)
Urinalysis by dipstick with microscopy
Urinalysis; two or three glass test (for the presence of blood 1—at the beginning of the urine stream, 2—midstream, and/or 3—at the termination of urination)
Fecal leukocyte examination
Semen analysis (for presence or motility of sperm)
Nasal smears for eosinophils

base of the microscope by the arm. The microscope arm is also the location of the focus controls. The two focus controls—coarse and fine—move the body tube up and down to bring into focus the object being examined.

Stage and Substage The objectives and oculars are focused on a specimen placed on the microscope's stage. The stage is the platform on which the specimen slide rests, held in place by metal clips. Located directly under the stage is the substage. This is where the condenser, which concentrates the light and focuses it through the sample on the slide, is located. Also located on the substage is the iris. The iris is a diaphragm that opens and closes like the shutter of a camera to increase or decrease the amount of light illuminating the specimen. The stage is controlled by the stage mechanisms, which control left-right and forward-backward movements of the stage, allowing you to examine different areas of the specimen without reseating the slide.

Light Source Under the stage and substage assemblies is the light source. Most POL microscopes use a built-in electric light source, and most of these are equipped with controls that allow you to adjust the light intensity. In place of a built-in light source, older microscopes use a mirror, which gathers and focuses light from a microscope lamp onto the specimen.

Specimen Slides and Coverslip Although the specimen slide is not technically part of the microscope assembly, it is necessary for using the microscope. All specimens must be placed on slides. Many specimens also require a coverslip, or cover glass. The slide and coverslip support and position the specimen. They also prevent contamination of the microscope by the specimen. Specimens that are to be stained or immersed in oil, such as blood smears, do not require coverslips.

Using an Optical Microscope To use an optical microscope, you must be able to focus it using each of the three

objectives. Procedure 45-1, at the end of this chapter, describes how to operate an optical microscope correctly.

You also will be responsible for the proper care and maintenance of the optical microscope in your office. Related concerns and techniques are described in the *Caution: Handle with Care* feature.

Electronic Equipment and Software

Electronic equipment is used in the POL because it is safer, more accurate, and more efficient than manual methods; generally requires little maintenance; and does not require extensive training prior to its use. A wide variety of tasks, such as cell counting and complex chemical analyses, are performed with electronic equipment. A range of clinical laboratory software systems are available, which are used to create and maintain clinical data, making remote access and tracking between facilities easier. Manufacturers' instructions for operation and maintenance of these systems must be followed to ensure safety, efficiency, and reliable results.

A **photometer**, which measures light intensity, is a basic electronic component of many pieces of analytic laboratory equipment. A handheld glucometer (Figure 45-3), for example, contains a photometer that measures reflected light. Patients with diabetes and clinical personnel use a glucometer to monitor blood glucose levels.

Equipment Used for Measurement

Precise measurement is critical in the POL because it produces accurate test results. Much of this measurement is built into the electronic equipment or premeasured kits you will use. However, you will still need to perform various

CAUTION: HANDLE WITH CARE

Care and Maintenance of the Microscope

The microscope is the workhorse of the POL. For it to provide trouble-free service, however, it must be well cared for. Dust, oil, and other contaminants cause major problems with microscopes. Careless cleaning and haphazard storage will also eventually cause problems. These problems may include mechanical difficulties with the microscope or contamination of the specimen being examined. Foreign objects visible through a microscope, but unrelated to the specimen, are called **artifacts** and may be misinterpreted when the specimen is examined.

Clean the microscope after each use. Inspect the body tube, arm, and stage to make sure they are dust- and contaminant-free. Clean the ocular and objective lenses with lens paper, not tissue or other products. Tissue fibers are a common artifact. The eyepiece is an area in which skin oil, dust, and eye makeup

may collect, posing a risk of disease transmission and making images difficult to see. Use lens-cleaning products according to the manufacturer's guidelines. Excess amounts of these products may dissolve the cement holding the lenses in place, rendering the microscope useless.

When not in use, the microscope should be stored under its plastic cover. If there is a power cord, wrap it loosely around the base and secure it with a twist-tie or elastic band. Lower the low-power objective close to the stage and center the stage.

If the microscope must be moved, hold it by the arm and support it under the base. Never carry a microscope with one hand or by just the arm. Carry the cord so that it does not dangle and pose a tripping hazard. Place the microscope on a sturdy table or bench, away from the edge.

FIGURE 45-3 A handheld glucometer translates the amount of reflected light into the level of glucose in a blood sample.

© Leesa Whicker

measurements manually when blood, semen, urine, and other body fluids are analyzed using manual tests. Some reagents also require measuring.

Metric system units are commonly used in the POL. For information on metric system weight, height, and temperature measurements, see the *Vital Signs and Measurements* chapter. To learn how to convert between measurement systems, see the *Math and Dosage Calculation* chapter.

A variety of equipment is used to provide accurate measurements. You must take these measurements carefully for them to be of value in the final test results. Other types of measuring equipment include

- Pipettes (mechanical or manual)—used to measure small amounts of liquids.
- Volumetric or graduated flasks or beakers—used to measure the relatively large amounts (volumes) of liquids necessary for reagents and solutions.
- A hemocytometer—a specialized slide calibrated to the exact measurements needed to count blood cells and sperm under a microscope.
- Thermometers (generally in degrees centigrade)—used to provide legal documentation that refrigerators, bacterial incubators, and other appliances maintain the precise temperature range required for accurate laboratory work.

► Safety in the Laboratory

LO 45.4

Safety is a primary concern in any laboratory environment, and it is especially important in a physician's office laboratory because patients and laboratory workers may be at risk. For

your own protection, as well as that of patients and coworkers, you must always be aware of and observe laboratory safety guidelines.

Use standard precautions when handling all body fluids, excretions, and secretions. If you have any doubt about whether you need to take precautions, take them. Even though some substances do not present a risk of transmitting blood-borne pathogens, they may present a high risk of transmitting other bacteria, viruses, or parasites. Follow these guidelines:

- Wear gloves when handling all body fluids, secretions, and excretions.
- Change gloves every time you move from patient to patient as you collect specimens for testing.
- Wash your hands immediately after removing used gloves.
- Wear other protective gear such as eye protection and face masks during procedures in which there is a risk that droplets or spray may come in contact with your eyes, nose, or mouth.
- Take special care to avoid injury from sharp or pointed instruments or equipment. Although gloves protect you from surface exposure to potentially infected substances, they offer little protection against exposure from needlesticks or cuts. Never use needles or other sharp instruments unnecessarily.
- Use only recommended instruments and equipment. A once-common laboratory technique that has been discontinued is the use of a mouth pipette (a type of calibrated glass or plastic straw) to transfer specimens. Under no circumstances should you use a mouth pipette to transfer blood from one collection device to another; doing so puts you at risk for getting blood or other hazardous fluids in your mouth.
- Take care to prevent spills and splashes when transporting specimens to the laboratory and when moving specimens in the laboratory.
- If a work surface becomes contaminated because of spilling or splashing, disinfect the area completely, using an approved solution such as 10% bleach, before beginning any other procedure.
- Dispose of waste products carefully and correctly.
- Be sure to remove protective gear before leaving the laboratory.

Biologic Safety

You will work with test specimens that may be contaminated with bloodborne or other pathogens. Treat every specimen as if it were contaminated. Additional information regarding OSHA's Bloodborne Pathogens Standard may be found in the *Infection Control Fundamentals* chapter. Follow standard precautions.

- If you have any cuts, lesions, or sores, do not expose yourself to potentially contaminated material. Consult your supervisor if you have any doubt about whether you can safely perform test procedures.
- Wash your hands before and after every procedure and whenever you come in contact with a potentially contaminated substance.

- Wear gloves at all times. Use other protective gear as appropriate to prevent exposing your eyes, nose, and mouth to potentially contaminated material.
- Mouth pipetting is prohibited at all times. Use specially made rubber suction bulbs to draw specimens mechanically.
- Work in a biologic safety cabinet (similar to a fume hood) when completing procedures that are likely to generate droplet sprays or splashes of potentially contaminated material.
- When transferring a blood specimen from a collection tube to another container, wear appropriate PPE (including a mask and goggles or a face shield) and cover the tube stopper with an absorbent pad or a commercial stopper remover to prevent spray or splatter from the tube. Do not rock the stopper back and forth because this could cause the tube to break. Always remove the stopper by opening it away from your face so that the vapor pressure flows away from you. Place the stopper on a sterile gauze pad while you work with the collection tube. Do not allow the stopper to come in contact with other work surfaces. Keep the collection tube stoppered unless you are actively using it.
- Establish clean and dirty areas in the laboratory. Place all used instruments and equipment in the dirty area for sanitization, disinfection, and sterilization.
- Disinfect your work area at least once a day with a 10% bleach solution or a germ-killing solution approved by the Environmental Protection Agency (EPA). If a spill occurs, immediately disinfect the work area.
- Dispose of waste products immediately.
- Dispose of needles in the appropriate sharps container.
- If an instrument or piece of equipment must be serviced, be sure it has been decontaminated first.
- If you use a bleach solution for disinfection, change it daily.

Accident Reporting

Despite all precautions, laboratory accidents still occur. Armed with an understanding of the materials with which you are working and basic first-aid procedures, you should be able to deal with most emergencies. Your office also should have written procedures to follow in the event of an accident. Familiarize yourself with the procedures beforehand so that you will know what to do if an accident occurs.

If the accident involves exposure to blood or blood products, OSHA regulations require that several steps be followed:

1. Immediate cleaning of the area, including disinfection of contaminated surfaces and sterilization of contaminated instruments and equipment
2. Notification of a designated emergency contact, as identified in your office's safety manual
3. Documentation of the incident on a form similar to that shown in Figure 45-4, including the names of all parties involved, the names of witnesses, a description of the incident, and a record of medical treatments given to those involved

4. Medical evaluation and follow-up exam of the employees involved
5. Written evaluation of the medical condition of the involved individuals and testing for infection, provided that such testing does not violate confidentiality regulations

Housekeeping

There is a high risk of serious contamination in the laboratory, and housekeeping duties are designed to reduce this risk. Great care must be taken by following these guidelines to ensure good operating procedures and to reduce the risk of infection:

- Refer to your office's written policies and procedures to ensure that you are performing housekeeping duties correctly and according to schedule.
- Immediately clean up spills or splashes of potentially contaminated material. Depending on the material, you may need to use special hazardous waste control products, like those shown in Figure 45-5. Be sure to dry the area if appropriate, or clearly indicate that the area is still wet.
- Clean laboratory equipment immediately after use. Contaminants often become hard to remove if they are left on for a long time.
- Dispose of waste products carefully and correctly.
- Use extreme caution when handling and disposing of sharps.

► Quality Assurance Programs

LO 45.5

The operation of a POL can have a significant impact on the health of the patients who depend on the medical practice for care. Accurate patient specimen testing is a primary concern. A **quality assurance program** is designed to monitor the quality of the patient care a medical laboratory provides. It also helps to ensure laboratory worker safety. An effective quality assurance program should be a written plan that includes both internal and external reviews of procedures. It assesses the quality of the tests performed in a clinical laboratory based on a set of written standards and procedures.

Clinical Laboratory Improvement Amendments

In response to public concern over the accuracy of laboratory tests, Congress enacted the Clinical Laboratory Improvement Amendments of 1988 (CLIA '88). This law placed all laboratory facilities that conduct tests for diagnosing, preventing, or treating human disease or for assessing human health under federal regulations administered by the Centers for Medicare and Medicaid Services (CMS) and the CDC. State governments may implement their own standards, which must be at least as stringent as federal standards. If your state has its own standards, your office will operate under those standards. The state health department provides information about which standards to follow in a given locale.

**Central State Division
Incident Report**

Name of Injured Employee _____

FIGURE 45-4 In the event of an accident or exposure incident in the POL, OSHA regulations require completion of an incident report form.

CLIA '88 has had a major impact on office laboratories. Because of the complexity of the regulations and the expense required to meet them, many doctors have closed their laboratories or sharply reduced the number of tests they perform. Several attempts have been made to change the federal legislation, including an effort to exempt POLs from the regulations. As the healthcare debate continues, you may see changes

in laboratory operations as a result of changes in CLIA '88 regulations.

CLIA '88 standards apply to four areas of laboratory operation:

- Standards—requirements for maintaining a laboratory; specific standards are determined by the complexity of the test

FIGURE 45-5 Certain substances require cleanup with specially formulated products such as these.

Courtesy Safetec of America

- Fees—charges for maintaining a laboratory
- Enforcement—penalties imposed for violating CLIA standards
- Proficiency testing programs—for laboratories that perform moderate- to high-complexity testing; labs in this category must go through a special inspection and assessment to perform tests that are moderately or highly complex

Most of the regulations relate to laboratory standards. Tests have been divided into these three categories, based on complexity: Certificate of Waiver tests, tests of moderate complexity, and tests of high complexity.

Certificate of Waiver Tests The **Certificate of Waiver tests**, as listed in Table 45-2, are simple laboratory examinations and procedures that have an insignificant risk of an erroneous result. These tests are often performed in a POL. In order for a test to be classified as a waived test, it must

- Pose an insignificant risk to the patient if it is performed or interpreted incorrectly.
- Involve procedures that are simple and accurate so that the risk of obtaining incorrect results is minimal.
- Be approved by the Food and Drug Administration (FDA) for use by patients at home.

If laboratory management decides to perform these tests only, the office may apply for a Certificate of Waiver. When the certificate is granted, the laboratory is exempt from meeting various CLIA '88 standards that apply to the other two test categories. Such laboratories, however, are subject to the following: (1) random inspections to ensure that laboratories

operating under a Certificate of Waiver are performing only those tests that qualify for the waiver and (2) investigation of the laboratory if there is any reason to believe the laboratory is not operating safely or if there have been complaints against the laboratory. See the *Caution: Handle with Care* feature Operating a Reliable Certificate of Waiver Laboratory for more information about good lab practice.

Tests of Moderate Complexity Tests of moderate complexity make up approximately 75% of all tests performed in the laboratory. Among these tests are blood cell counts and cholesterol screening. Test procedures falling into this category include studies involving bacteriology, mycobacteriology, mycology, parasitology, virology, immunology, chemistry, hematology, and immunohematology.

A laboratory that performs moderate-complexity testing must be run by a pathologist who has an MD or PhD degree. Technicians performing the tests must have training beyond the high school level as defined by CLIA '88 regulations. All personnel must participate in a quality assurance program for laboratory procedures, and the laboratory is subject to periodic unannounced inspections and proficiency testing.

Tests of High Complexity Tests of high complexity include more complicated tests in the specialties and subspecialties, including tests in clinical cytogenetics, histopathology, histocompatibility, cytology, and any test not yet categorized by the CMS. Manufacturers' guidelines for testing products are often the best source for discovering a test's CMS determination. The CMS publishes a directory of all moderate- and high-complexity tests.

Like a laboratory that conducts moderate-complexity tests, a laboratory that conducts high-complexity tests is subject to inspection, proficiency testing, and participation in a quality assurance program, and it must be headed by a medical doctor or a scientist who has a PhD degree. Testing procedures can be performed only by qualified laboratory personnel whose training exceeds that provided by high schools and meets the requirements of CLIA '88 regulations. Medical assistants will need additional training and education to perform moderate- and high-complexity tests.

Components of Quality Assurance

Every quality assurance program must include the following components, in a measurable and structured system, to satisfy CLIA '88 requirements:

- Quality control
- Instrument and equipment maintenance
- Proficiency testing
- Training and continuing education
- Standard operating procedures documentation

Quality Control and Maintenance

A **quality control program** is one component of a quality assurance program. The focus of the quality control program is to ensure accuracy in test results through careful monitoring of test procedures. To be in compliance with quality control standards, a laboratory must follow certain procedures.

TABLE 45-2 Certificate of Waiver Tests

Urine Tests	Urinalysis by dipstick (reagent strip) or tablet reagent (nonautomated) for bilirubin, glucose, hemoglobin, ketone, leukocytes, nitrite, pH, protein, specific gravity, and urobilinogen Ovulation (visual color comparison tests) Pregnancy (visual color comparison tests) Home-screening tests for drugs (opioids, cocaine, methamphetamines, cannabinoids, phencyclidine, methadone, benzodiazepines, barbiturates, oxycodone) Nicotine detection tests Urine chemistry analyzer for microalbumin and creatinine (semi-quantitative) Tumor-associated antigen for bladder cancer (using devices approved by the FDA for home use) Catalase Ascorbic acid
Blood Tests	Erythrocyte sedimentation rate (ESR), nonautomated Hemoglobin by copper sulfate, nonautomated Spun microhematocrit Blood glucose (using devices approved by the FDA for home use) Hemoglobin by single analyte instruments, automated Prothrombin time Platelet aggregation Ketones in whole blood, over-the-counter test only Total cholesterol, high-density lipoprotein (HDL), low-density lipoprotein (LDL), and triglycerides Hemoglobin A1C Liver panel (alanine aminotransferase, alkaline phosphatase, amylase, gamma glutamyl transferase, aspartate aminotransferase, total bilirubin) Lactate in whole blood Chloride Carbon dioxide Calcium Sodium Potassium Urea Uric acid Creatinine Lead in whole blood Thyroid-stimulating hormone, rapid test Mononucleosis rapid test <i>Helicobacter pylori</i> rapid antibody test Lyme disease antibodies HIV antibody test
Fecal Tests	Fecal occult blood
Saliva Tests	Alcohol in saliva
Nasal Smear Tests	Adenovirus Influenza A and B antigens Respiratory syncytial virus
Vaginal Smear Tests	<i>Trichomonas vaginalis</i> antigens Vaginal pH
Throat Swab Tests	Strep A antigens Influenza A and B
Semen	Sperm concentration, home screening

CAUTION: HANDLE WITH CARE

Operating a Reliable Certificate of Waiver Laboratory

CLIA requires that Certificate of Waiver laboratories obtain a certificate of waiver, pay biennial certificate fees, and follow manufacturers' test instructions. They also require that Certificate of Waiver laboratories submit to random inspections and investigation if indicated. CLIA does not require laboratory personnel to have any specific qualifications or training, nor do they require quality control procedures or routine quality assessment, except as recommended by the manufacturer of each waived test. Although waived tests are simple to perform and interpret, they may have serious consequences if done incorrectly. Patient care decisions are often made based on the outcome of waived tests.

In order to help ensure quality testing procedures and reduce patient error, the Clinical Laboratory Improvement Advisory Committee (CLIAAC) has made several recommendations for good practice in a Certificate of Waiver laboratory. These include laboratory management considerations and testing procedures before, during, and after the test. To ensure that you are operating a reliable laboratory, follow these recommendations:

Laboratory Management and Personnel

- Designate the person who will be responsible for laboratory supervision—usually a physician or someone with enough laboratory experience to make decisions about testing.
- Follow all applicable federal, state, and local regulations.
- Perform waived tests only.
- Follow the manufacturer's instructions in the package insert.
- Do not make modifications to the instructions.
- Allow random inspections by authorized agencies such as the Centers for Medicare and Medicaid Services (CMS).
- Establish a laboratory safety plan that follows OSHA guidelines.
- Have a designated area that has adequate space and conditions.
- Have enough personnel in the lab and train them appropriately.
- Have written documentation of each test performed.

Before the Test

- Confirm written test orders.
- Establish a procedure for patient identification.
- Give patients pretest instructions and determine whether they have followed them.
- Collect specimens according to package insert instructions.
- Label specimens appropriately.
- Never use expired reagents of test kits.

During the Test

- Perform quality control testing as indicated in the package insert.
- Correct any problem discovered during quality control testing before testing patient samples.
- Establish a policy for control testing frequency.
- Carefully follow all test-timing recommendations.
- Interpret test results using product inserts as a guide.
- Record test results according to your office policy.

After the Test

- Report test results to the physician in a timely manner.
- Follow package insert recommendations for follow-up or confirmatory testing.
- Follow OSHA regulations for disposing of biohazardous waste.
- Participate in quality assurance assessment programs:
 - Internal assessment—routine, in-house testing to ensure a test's accuracy
 - External assessment—voluntary inspection of your facility by an outside agency

Calibration Medical equipment used for testing patient specimens must be calibrated regularly, in accordance with manufacturers' guidelines. Calibration ensures that the equipment is operating correctly and is producing accurate results. In order to calibrate a medical instrument, you must have a set of known standards. A **standard** is a specimen, like the patient specimens you would normally process with the equipment, except that the value for each standard is already known. When you calibrate medical equipment, you run the standard with the known value. If the results do not match the known value, then the equipment is not in calibration. If the equipment does not yield the expected results during the calibration procedure, it must be adjusted until the expected

results are obtained. Each calibration must be recorded in a quality control log like the one shown in Figure 45-6. Calibration routines are run on the standards alone, never with patient samples. They are used exclusively to ensure that the equipment is performing according to manufacturers' specifications. Check the manufacturer's instructions to determine how often the equipment should be calibrated. Calibration of some equipment must be performed by trained service personnel.

Control Samples Control samples are similar to standards in that they are specimens like those taken from a patient and have known values. Unlike standards, however, control samples are used before each patient sample is processed.

QUALITY CONTROL DAILY LOG

Name of Unit	Glucose Control Solution	Strip Lot No./ Exp. Date	Low Control Value 35–65 mg/dL	High Control Value 75–235 mg/dL	Analyzed By	Date	Remedial Action Taken If Control Values Abnormal	Retest After Remedial Action Taken

Mitchell Drugs Glucometer	Check-strip control solution	Lot 851 10/15/XX	45 mg/dL	226 mg/dL	LMC	1/18/XX		

FIGURE 45-6 The quality control log shows the completion of every quality control check conducted on a piece of equipment.

Using a control sample serves as a check on the accuracy of the test. If the control tests do not fall within the manufacturer's prescribed ranges, patient samples should not be analyzed until the equipment is calibrated. This helps prevent erroneous patient test results.

The control samples for certain laboratory procedures show both normal (negative) and abnormal (positive) results. Generally, positive and negative control samples are used with tests that yield that **qualitative test response**. A qualitative test is testing to see if the substance is present in the specimen. It is not testing for the amount of a substance in the specimen, only if it is there or not.

Tests that yield **quantitative test results** require different control samples. Quantitative tests give the concentration or amount of a substance in a tested specimen. Control samples are formulated to show when results fall within a normal range. At least two control samples containing different concentrations—usually a high and a low value—of the test substance should be run for quantitative tests.

Reagent Control Control samples or standards are also run every time you open a new supply of testing products, such as staining materials, culture media, and reagents. **Reagents** are chemicals or chemically treated substances used in test procedures. A reagent is formulated to react in specific ways when exposed under specific conditions. One example of a reagent is the chemically coated strip used in blood glucose monitoring. A visual change on the reagent strip (also called a dipstick) occurs in the presence of glucose in a blood sample.

To ensure the quality of reagents, you should keep a reagent control log. If a defective reagent test is identified, it can be tracked to its source. A sample reagent control log is shown in Figure 45-7. Running controls on a routine basis

gives you information about the equipment and the reagents used during the test. If a control consistently yields unexpected results (for example, a positive control yields a negative result), you should check the reagents first and then the equipment calibration.

Maintenance Testing instruments and equipment must be properly maintained, and all maintenance procedures must be documented. Follow manufacturers' guidelines for performing instrument and equipment maintenance. A maintenance log provides a complete record of all work performed on an instrument or a piece of equipment (Figure 45-8).

Troubleshooting You may need to investigate the cause of a problem with a piece of equipment or a test. To do this, you should take a systematic approach to rule out the cause of the problem. For more information regarding investigating equipment and test malfunctions, see the *Caution: Handle with Care* feature Troubleshooting Problems in a Physician's Office Laboratory.

Documentation A quality control program depends first on careful adherence to procedures designed to identify problems with equipment calibration, errors in testing procedures, and defective testing supplies. The second component of a quality control program is the careful documentation of all procedures. Besides maintaining the quality control log, the reagent control log, and the equipment maintenance log, you also will complete the following records as part of a quality control program:

- Reference laboratory log, which lists specimens sent to another laboratory for testing
- Daily workload log, which shows all procedures completed during the workday

URINE REAGENT STRIP CONTROL LOG										Control Solution _____		Exp. Date _____		Lot # _____

	Test Results														

FIGURE 45-7 The reagent control log shows the quality testing performed on every batch or lot of reagent products.

Proficiency Testing

All laboratories that perform moderate- and high-complexity tests as identified by CLIA '88 must participate in a proficiency testing program. **Proficiency testing programs** measure test result accuracy and adherence to standard operating procedures. Generally, proficiency tests include two parts: (1) an unknown (testing) sample supplied by the proficiency testing organization contracted by your laboratory and (2) forms that must be completed

to record the steps in the testing procedure. The unknown sample is processed normally, under the same conditions as any patient sample. The results, the forms, and sometimes the unknown samples are returned to the proficiency testing organization, which then informs your office whether it has passed or failed the test. A passing mark means that your laboratory can continue to perform that particular test. A failing mark can mean that your laboratory must discontinue that test and possibly other tests, too.

CAUTION: HANDLE WITH CARE

Troubleshooting Problems in a Physician's Office Laboratory

Working in a physician's office laboratory can be exciting and challenging. Part of your job as a medical assistant is to make sure the tests you perform are accurate. Occasionally, you will encounter a piece of equipment that is not working or test results and controls that are consistently too high or too low. You will need to troubleshoot these problems to determine their cause. Troubleshooting is a thorough and logical investigation for the cause of a problem. You must eliminate possible causes of the problem one at a time. The general steps to troubleshooting a piece of equipment or test kit are

- Follow a written procedure for troubleshooting tests and equipment.
- Recognize the problem (controls give clues to possible problems).
- Think about possible causes.
- Start by investigating the simplest cause first.
- Document your findings.
- Call your service company after you have checked everything you know to check.

When troubleshooting equipment, follow these steps:

- Check the power source at the machine, the wall outlet, the breaker box, or the battery.
- Check the equipment manual for troubleshooting information.
- Reboot the equipment by turning it off, waiting a few minutes, and then turning it back on.
- Check the service log for the date of the last maintenance.
- If you are able to repair the problem, run controls to verify that the problem is fixed before testing patient samples.

When troubleshooting a test kit, follow these steps:

- Read the package insert to verify that you have performed the test correctly.
- Check to make sure you have used the correct reagents or test strips.
- Check the dates on the reagents or test strips to make sure they are not outdated.
- Make sure you are using the proper sample for the test.
- Repeat the test using control samples.
- If the controls are correct, repeat the test with the patient sample.

Training, Continuing Education, and Documentation

One of your employer's responsibilities is to provide opportunities for employee training and continuing education. Another is to provide written reference materials and documentation for all procedures conducted in the POL. Your responsibility is to consult reference materials and take part in available training to keep your skills sharpened and up to date.

It may seem unnecessary to refer to written instructions for procedures you perform many times a day. Changes can be made in a procedure for many reasons, however, and you must be aware of these changes. Here are some reference materials with which you should be familiar:

- Safety Data Sheets
- Standard operating procedures
- Safety manuals
- Equipment manufacturers' user or reference guides
- Clinical Laboratory Technical Procedure Manuals
- Regulatory documentation (OSHA standards, CLIA '88 requirements)
- Maintenance and housekeeping schedules

► Communicating with the Patient LO 45.6

In your job as a medical assistant, you will be involved with patients before they submit samples for laboratory testing, during the specimen collection procedure, and after the

physician has interpreted the test results. It is your responsibility to ensure that patients understand what is expected of them every step of the way.

Before the Test

Certain tests require patients to prepare by fasting or restricting fluid intake. It is your duty to explain test preparations. Use simple, nontechnical language and check with patients to be sure they understand the information. In some cases, providing a written instruction sheet may be helpful.

Explaining the reason for the preparation can help ensure compliance or unearth potential problems. For example, if you explain to a patient that he is to refrain from drinking anything for a particular period, he might ask whether that includes the water he uses to take a certain medication. You can then make sure the patient receives the answers he will need for carrying out the physician's orders.

If you are the person who collects specimens, you need to determine whether patients have correctly completed the required test preparations. Test results are invalid in some cases if patients fail to follow test preparation guidelines. When preparations have not been completed correctly, discuss the situation with the physician or other appropriate staff member as required by your office to determine whether the specimen should still be collected. If the specimen is not collected, document the reason the test was not carried out as requested. Review the guidelines for specimen collection with the patient, and schedule another appointment if appropriate.

During Specimen Collection

Before collecting a specimen, you must first be sure you have the right patient. Proper patient identification is an essential part of good laboratory practice. You do not want to collect a blood sample from someone who only needs a urinalysis. Patients do not always understand the tests they are having. It is up to you to make sure you have the right patient and are performing the test as it is ordered.

The instructions you deliver to patients during specimen collection vary with the nature of the specimen. Always deliver instructions clearly and in language patients can understand. Do not assume that patients do not need to hear the instructions, even if they have had the test before. Explain what you must do and what patients must do before moving to each new step in the process.

Patients are understandably nervous during many collection procedures. In addition to communicating technical information, you should provide any helpful advice that may make the test easier. Also provide reassurance as appropriate. For example, if a patient asks whether the blood-drawing procedure is painful, explain that a sharp stick or stinging sensation may be experienced when the needle is inserted but that no pain should be felt after that. Let the patient be your guide in determining how much information to provide. Some people want to know every detail, whereas others prefer to know as little as possible.

One important aspect of communicating with patients about testing procedures is your nonverbal communication skills. Even if you deliver accurate technical information and answer every question patients have, there can still be a breakdown in communication if your nonverbal signals do not support your verbal message. Follow these guidelines to ensure that your nonverbal actions are helping, not hindering, the communication process:

- Strike a balance between a strict, business-like attitude and overly familiar friendliness. Your actions must impress on the patient that you are well informed about the procedure and that you care about the patient's understanding of it.
- Treat the patient with respect. Address the patient by name, using the appropriate courtesy title unless you have been invited to use the patient's first name or the patient is a child. Provide privacy during specimen collection. Privacy needs may be met by using a separate room or contained area for drawing blood, for example; a private bathroom is best for collecting urine specimens.
- Recognize that the patient may be under stress because of the test procedure or the pending results. Some patients may be familiar with the test procedures, but others may not know what to expect. You may need to repeat instructions or explain what you are doing more than one time. Remain calm and patient. Never be abrupt or condescending.
- Direct your attention to the patient, particularly during a procedure that might be uncomfortable, like drawing blood. Unless an emergency develops, pay attention to nothing else at that time.

After Specimen Collection

If the patient must follow particular guidelines after you collect the specimen, explain them. Commonly, post-test instructions deal with the care of venipuncture sites, signs and symptoms of infection, additional or continuing dietary restrictions, and the schedule for further testing if it is necessary.

When the Test Results Return

When you receive the test results, communicate them not to the patient but to the doctor. Only the doctor is qualified to interpret test results for the patient. Your role in reporting results comes after the doctor examines the test information and prepares a report. Sometimes, the doctor discusses the results with the patient. Other times, you will be asked to convey the test results to the patient along with instructions from the doctor. Answer only those patient questions that are within the range of your knowledge and experience. If the patient needs more information than you can provide, refer the patient to the doctor.

▶ Recordkeeping

LO 45.7

The importance of accurate and complete recordkeeping can be summed up in one statement: If it is not written down, it was not done. This motto applies to all your duties as a medical assistant. Besides recording information about quality control and equipment maintenance, you must keep track of every specimen that passes through your hands, or you may be called on to handle inventory control and record test results in patient records. You may need to use standard abbreviations for measures when recording test results. Table 45-3 provides a list of common abbreviations used in the laboratory.

Filling Out a Laboratory Requisition Form

As a medical assistant, it is your responsibility to ensure that the laboratory requisition form is properly completed. Missing information can lead to improper testing or lost results. The completed form should be included with the specimen collected or sent with the patient to the laboratory. Be sure to include the following information on all requisitions:

- Patient's full name, sex, date of birth, and address
- Patient's insurance information
- Physician's name, address, and phone number
- Source of the specimen
- Date and time of the specimen collection
- Test(s) requested
- Preliminary diagnosis
- Any current treatment that might affect the results

See Figure 45-9 for a sample laboratory requisition form.

Specimen Identification

All specimens must immediately be clearly identified with the patient's name, the patient's identification code (if your office uses one), the date and time the specimen was collected,

the initials of the person who collected the specimen, the physician's name, and other information as required by the test procedure or your office. If you encounter an unidentified or incorrectly identified specimen, you must make an effort to track it to its source. The specimen will probably be discarded or destroyed, however, because there is no guarantee that it was identified correctly. Even if you do manage to identify it, it may have been compromised in some way.

Inventory Control

You will be responsible for taking inventory of equipment and supplies to ensure that the POL never runs out of them. To do so, you will keep a list of items that are used routinely and reordered systematically. Establish a regular schedule—perhaps weekly—for counting items in the POL. Then estimate when you will probably need to reorder an item—based on how quickly you use the item or material—and put the date on your calendar.

Patient Records

When recording test results, it may be your responsibility to identify unusual findings. Many offices require out-of-range test results to be circled or underlined in red. Follow the procedure established by your office. The physician usually initials or otherwise marks the records after examining them. Electronic health records automatically identify out-of-range tests when the results are entered.

PROCEDURE 45-1 Using a Microscope

Procedure Goal:

To correctly focus the microscope using each of the three objectives for examination of a prepared specimen slide

OSHA Guidelines:

Materials:

Microscope, lens paper, lens cleaner, prepared specimen slide, immersion oil, and tissues

Method:

1. Wash your hands and don exam gloves.
2. Remove the protective cover from the microscope. Examine the microscope to make sure it is clean and that all parts are intact.
3. Plug in the microscope and make sure the light is working. If you need to replace the bulb, refer to the manufacturer's guidelines. (Be sure to note bulb replacements in the maintenance log for the microscope.) Turn the light off before cleaning the lenses.
4. Clean the lenses and oculars with lens paper. Avoid touching the lenses with anything except lens paper. Pay careful

attention to the oculars, as they are easily dirtied by dust and eye makeup. If a lens is particularly dirty, use a small amount of lens cleaner. Oil-immersion lenses are prone to oil buildup if not cleaned properly. Too much lens cleaner, however, can loosen the cement that holds the lens in place.

RATIONALE: *The lenses must be clean to reduce artifacts.*

5. Place the specimen slide on the stage. Slide the edges of the slide under the slide clips to secure the slide to the stage.

FIGURE Procedure 45-1 Step 5 Carefully secure the specimen slide on the stage of the microscope.

© McGraw-Hill Education

6. Adjust the distance between the oculars to a position of comfort.

7. Adjust the objectives so the low-power ($10\times$) objective points directly at the specimen slide, as shown. Before swiveling the objective assembly, be sure you have sufficient space for the objective. Recheck the distance between the oculars, making sure the field you see through the eyepieces is a merged field, not separate left and right fields. Raise the body tube by using the coarse adjustment control and lower the stage as needed.

RATIONALE: *If the objective assembly is too close to the stage, you may hit the specimen slide and crack it. The specimen is then contaminated and cannot be used. The objective also may be damaged.*

FIGURE Procedure 45-1 Step 7 Move the low-power objective into position above the specimen slide.

© McGraw-Hill Education

8. Turn on the light and, using the iris controls, adjust the amount of light illuminating the specimen so that the light fills the field but does not wash out the image. (At this point, you are not examining the specimen image for focus but adjusting the overall light level.)
9. Observe the microscope from one side and slowly lower the body tube to move the objective closer to the stage and specimen slide. This adjustment is shown below. If you used the stage controls to lower the stage away from the objectives, you also may need to adjust those controls. Again, take care not to strike the stage with the objective. The objective should almost meet the specimen slide but not touch it.

FIGURE Procedure 45-1 Step 9 When lowering the objective toward the stage and specimen slide, observe the microscope from the side to be sure you do not hit the stage with the objective and crack the slide.

© McGraw-Hill Education

10. Look through the oculars and use the coarse focus control to slowly adjust the image. If necessary, adjust the amount of light coming through the iris.
 11. Continue using the fine focus control to adjust the image. When the image is correctly focused, the specimen will be clearly visible and the field illumination will be bright enough to show details but not so bright that it is uncomfortable to view or washed out.
 12. Switch to the high-power ($40\times$) objective. Use the fine focus controls to view the specimen clearly.
- RATIONALE:** *Using the coarse adjustment could cause lens damage if the lens touches the slide.*
13. Rotate the objective assembly so that no objective points directly at the stage and specimen slide. You will now have enough room to apply a drop of immersion oil to the slide. (Only dry slides, without coverslips, are used with the oil-immersion objective.)
 14. Apply a small drop of immersion oil to the specimen slide, as shown below.

FIGURE Procedure 45-1 Step 14 Place a small drop of immersion oil directly on the dry specimen.

© McGraw-Hill Education

15. Gently swing the oil-immersion ($100\times$) objective over the stage and specimen slide so that it is surrounded by the immersion oil.
16. Examine the image and adjust the amount of light and focus as needed. Only use the fine focus adjustment with this objective. To eliminate air bubbles in the immersion oil, gently move the stage left and right.
17. After you have examined the specimen as required by the testing procedure, lower the stage and raise the objectives.
18. Remove the slide. Dispose of it or store it as required by the testing procedure. If you must dispose of the slide, be sure to use the appropriate biohazardous waste container. If you must store the slide, remove the immersion oil with a tissue.
19. Turn off the light. Unplug the microscope if that is your laboratory's standard operating procedure.
20. Clean the microscope stage, ocular lenses, and objectives. Be careful to remove all traces of immersion oil from the stage and oil-immersion objective. Clean the oil-immersion lens last.

FIGURE Procedure 45-1 Step 20 Clean the oil-immersion lens last using a small amount of lens cleaner.

© McGraw-Hill Education

RATIONALE: *So that you do not get oil from the oil-immersion lens on the other lenses*

21. Rotate the objective assembly so that the low-power objective points toward the stage. Lower the objective so that it comes close to but does not rest on the stage.
22. Cover the microscope with its protective cover. Check the work area to be sure you have cleaned everything correctly and disposed of all waste material.
23. Remove the gloves and wash your hands.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
45.1 Describe the purpose of the physician's office laboratory.	The physician's office laboratory (POL) is responsible for accurate and timely processing of routine tests, usually involving blood or urine, and for reporting test results to the physician.
45.2 Identify the medical assistant's duties in the physician's office laboratory.	The medical assistant's duties in a physician's office laboratory include preparing the patient for the test, collecting the sample, completing the test, reporting the results to the physician, and communicating information about the test from the physician to the patient.
45.3 Identify important pieces of laboratory equipment.	Common laboratory equipment includes autoclaves, centrifuges, microscopes, electronic equipment and software, and equipment used for measurement.
45.4 Illustrate measures to prevent accidents.	Preventing accidents in the physician's office laboratory begins by observing all safety guidelines, including standard precautions, reporting all laboratory accidents in a timely manner, and maintaining appropriate housekeeping in the lab setting.
45.5 Explain the goal of a quality assurance program in a physician's office laboratory.	The goal of a quality assurance program in a physician's office laboratory is to monitor the quality of the patient care that a medical laboratory provides.
45.6 Carry out communication with patients regarding test preparation and follow-up.	It is the medical assistant's responsibility to ensure that patients understand what is expected of them before a test. Providing clear pretest instructions in both oral and written form is an essential part of the test procedure.
45.7 Carry out accurate documentation, including all logs related to quality control.	Accurate quality control documentation in a physician's office laboratory includes a reference laboratory log and a daily workload log.

CASE STUDY CRITICAL THINKING

© McGraw-Hill Education

Recall Sylvia Gonzales from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. Identify equipment used by a medical assistant in an office laboratory.
2. You will be measuring Sylvia's fasting blood glucose using a glucometer. You know this is classified as a waived test. What does the classification of waived test mean?
3. The glucometer contains an instrument called a photometer. How is blood glucose measured using a photometer?
4. Measuring blood glucose is a quantitative test. What does this mean?
5. What type of controls do you expect to use when measuring Sylvia's blood glucose?
6. When should you run the controls?

EXAM PREPARATION QUESTIONS

1. (LO 45.1) A laboratory owned by a company other than the physician's practice is a
 - a. Physician's office laboratory
 - b. Reference laboratory
 - c. Pathology department
 - d. Waived testing center
 - e. High-complexity testing center
2. (LO 45.3) The eyepieces on a microscope are also called
 - a. Objectives
 - b. Condensers
 - c. Oculars
 - d. Irises
 - e. Stages
3. (LO 45.3) An object visible through a microscope but unrelated to the specimen is a(n)
 - a. Iris
 - b. Aperture
 - c. Artifact
 - d. Speck
 - e. Inclusion
4. (LO 45.5) A simple laboratory examination or procedure that has an insignificant risk of an erroneous result is a
 - a. Waived test
 - b. Moderate-complexity test
 - c. High-complexity test
 - d. Quality assurance test
 - e. Reference test
5. (LO 45.5) Which of the following is a test to determine the amount of a substance in a specimen?
 - a. Qualitative
 - b. Waived
 - c. Complex
 - d. Quantitative
 - e. Assurance
6. (LO 45.3) A device for spinning a specimen at high speed until it separates into its component parts is a
 - a. Refractometer
 - b. Photometer
 - c. Concentrator
 - d. Condenser
 - e. Centrifuge
7. (LO 45.4) The most common disinfectant used in a physician's office laboratory is
 - a. Germicidal soap
 - b. 10% bleach
 - c. Hydrogen peroxide
 - d. Betadine®
 - e. 70% alcohol
8. (LO 45.5) A laboratory that performs moderate-complexity testing must be run by a
 - a. Pathologist
 - b. Medical technologist
 - c. Medical assistant
 - d. Medical lab specialist
 - e. CLIA-trained employee
9. (LO 45.5) Chemicals or chemically treated substances used in test procedures are known as
 - a. Controls
 - b. Standards
 - c. Reagents
 - d. Strips
 - e. Negatives
10. (LO 45.3) An instrument used in a medical laboratory to measure light intensity is called a(n)
 - a. Photometer
 - b. Microscope
 - c. Condenser
 - d. Analyte
 - e. Reflector

You are working in the lab today for Heather, who is out sick. Taylor brings you two tubes of blood and asks you to perform a blood glucose test for Mrs. Gonzales. After Taylor leaves the lab, you notice that one of the tubes is not labeled and the other tube has only the letter *S* written on it. What action should you take?

also has had a persistent cough and sore throat for the last 3 months. The physician orders a series of blood tests, including the helper T-cell test and a throat culture. Dr. Whalen asks you to send the throat culture to the reference lab for culture instead of doing a rapid strep test in the office.

Keep Cindy in mind as you study the chapter.

There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 46, you will be able to:

- 46.1** Explain the medical assistant's role in microbiology.
- 46.2** Summarize how microorganisms cause disease.
- 46.3** Describe how microorganisms are classified and named.
- 46.4** Discuss the role of viruses in human disease.
- 46.5** Discuss the role of bacteria in human disease.
- 46.6** Discuss the role of protozoans in human disease.
- 46.7** Discuss the role of fungi in human disease.
- 46.8** Discuss the role of multicellular parasites in human disease.
- 46.9** Describe the process involved in diagnosing an infection.
- 46.10** Identify general guidelines for obtaining specimens.
- 46.11** Carry out the procedure for transporting specimens to outside laboratories.
- 46.12** Compare two techniques used in the direct examination of culture specimens.
- 46.13** Carry out the procedure for preparing and examining stained specimens.
- 46.14** Carry out the procedure for culturing specimens in the medical office.

KEY TERMS

- | | |
|-------------------------------|---------------|
| acid-fast stain | facultative |
| aerobe | Gram-negative |
| agar | Gram-positive |
| anaerobe | Gram stain |
| bacillus | KOH mount |
| coccus | mordant |
| colony | spirillum |
| culture | stain |
| culture and sensitivity (C&S) | vibrio |
| etiologic agent | |

I.C.9 Analyze pathology for each body system including:
(a) diagnostic measures

I.P.11 Obtain specimens and perform:
(e) CLIA waived microbiology test

III.C.1 List major types of infectious agents

XII.P.1 Comply with:
(a) safety signs
(b) symbols
(c) labels

3. Medical Terminology

c. Apply various medical terms for each specialty

4. Medical Law and Ethics

a. Follow documentation guidelines

9. Clinical Procedures

a. Practice standard precautions and perform disinfection/sterilization techniques

10. Medical Laboratory Procedures

a. Practice quality control

b. Perform selected CLIA-waived tests that assist with diagnosis and treatment

(4) Immunology testing

(5) Microbiology testing

(6) Kit testing

b. Quick strep

c. Dispose of biohazardous materials

d. Collect, label, and process specimens

(3) Perform wound collection procedures

(4) Obtain throat specimens for microbiologic testing

► Introduction

Humans are surrounded by tiny, living organisms invisible to the naked eye. For the most part, these microorganisms cause no problems; however, when they are pathogenic in nature or are displaced from their natural environment, they can cause infections and disease. This chapter addresses the different life forms of microorganisms and how they may be identified; it also teaches you the proper collection techniques for common types of specimens. You will learn about the processes involved in identifying microorganisms, the types of culture media used for these processes, how antimicrobial testing is done, and how quality control fits into ensuring reliable patient results.

► Microbiology and the Role of the Medical Assistant

LO 46.1

Microbiology is the study of *microorganisms*—simple forms of microscopic (visible only through a microscope) life found everywhere. Most microorganisms are made up of a single cell. Some microorganisms, called resident normal flora, which are normally found on the skin and within the human body, perform a number of important functions and typically do not cause disease. For example, microorganisms in the intestines produce vitamins, help digest food, and help protect the body from infection.

Microorganisms capable of causing disease are known as pathogens. The infections caused by microorganisms can be

mild, like the common cold, or they can lead to serious conditions. Their proper diagnosis and treatment are essential to restoring good health.

You may assist the physician in performing a number of microbiologic procedures in the medical office that aid in diagnosing and treating infectious diseases, including obtaining specimens or assisting the physician in doing so, preparing specimens for direct examination by the physician, and preparing specimens for transportation to a microbiology laboratory for identification.

► How Microorganisms Cause Disease

LO 46.2

Microorganisms live all around us—in and on our bodies, in the air we breathe, in the water we drink, and on almost every surface we touch. The variety of pathogenic microorganisms is extensive. Successful pathogens have developed ways to evade the host defenses. Each classification of microorganism contains pathogens. Some examples of these appear in Table 46-1.

Although everyone is surrounded by microorganisms, people are able to avoid infection most of the time for the following three reasons:

1. The majority of microorganisms are either beneficial or harmless. Pathogens comprise only a small portion of the total number of microorganisms that exist in a given environment.

TABLE 46-1 Microbial Pathogens and Their Characteristics

Classification	Characteristics	Example	Disease
Prions*	• Infectious particle made of protein • Very small • No nucleic acid • Reproduction unknown	PrP ^{Sc}	• Creutzfeldt-Jakob disease (CJD) • Bovine spongiform encephalopathy (BSE), or mad cow disease
Viruses	• DNA or RNA surrounded by a protein coat • Reproduced in living cells only • Very small • Acellular	Varicella-zoster virus	Chickenpox
Bacteria	• Single-celled • Reproduce quickly • Mostly asexual reproduction	<i>Vibrio cholerae</i>	Cholera
Protozoans	• Single-celled • Mostly asexual reproduction	<i>Entamoeba histolytica</i>	Amebic dysentery
Fungi	• Multicellular • Sexual and asexual reproduction	<i>Candida albicans</i>	Candidiasis
Helminths	• Multicellular • Parasitic • Contain specialized organs • Sexual reproduction	<i>Enterobius vermicularis</i>	Pinworms

*Although evidence exists that prions are directly responsible for several diseases that cause progressive brain degeneration, such as spongiform encephalopathies, some scientists believe prions merely aid another, unknown infectious agent in causing disease. Prion research is ongoing.

2. The human body has a variety of defenses that allow it to resist infection.
3. Conditions must be favorable for a pathogen to grow and to be transmitted to a person who is susceptible (sensitive) to infection.

Microorganisms and Disease Mechanisms

Microorganisms can cause disease in a variety of ways. They may use up nutrients or other materials needed by the cells and tissues they invade, they may damage body cells directly by reproducing themselves within cells, or their very presence may make body cells the targets of the body's own defenses. Some microorganisms produce cell- and tissue-damaging toxins or poisons. Infecting microorganisms, or the toxins they produce, may remain localized or travel throughout the body, damaging or killing cells and tissues. The resulting symptoms include local swelling, pain, warmth, and redness, along with generalized symptoms of fever, tiredness, aches, and weakness. Infection by certain organisms also may cause skin reactions, gastrointestinal upset, or other symptoms. Recall from the *Infection Control Fundamentals* chapter the chain of infection and how pathogenic organisms are transmitted from one person to another.

► Classification and Naming of Microorganisms

LO 46.3

Scientists classify microorganisms on the basis of their structure. Common classifications include the following:

- Subcellular microorganisms, which consist of hereditary material, either deoxyribonucleic acid (DNA) or ribonucleic acid (RNA), surrounded by a protein coat
- Prokaryotic microorganisms, which have a simple cell structure with no nucleus and no organelles in the cytoplasm
- Eukaryotic microorganisms, which have a complex cell structure containing a nucleus and specialized organelles in the cytoplasm

Table 46-2 lists the characteristics that distinguish these classifications and the types of microorganisms found in each classification. Types of microorganisms include:

- Viruses
- Bacteria
- Protozoans
- Fungi
- Multicellular parasites

These types may be further divided into groups that share certain characteristics. For example, within the bacteria classification are the mycobacteria and rickettsiae groups.

Specific microorganisms are named in a standard way, using two words. The first word refers to the *genus* (a category of biologic classification between the *family* and the *species*) to which the microorganism belongs. The second word refers to the particular species of the organism. Each species represents a distinct kind of microorganism. For example, within the bacteria classification is the *Staphylococcus* genus. Then within that genus are various species such as *Staphylococcus aureus* and *Staphylococcus epidermidis*. Although

TABLE 46-2 Classifications of Microorganisms		
Classification	Characteristics	Examples
Subcellular	- Noncellular - Nucleic acid surrounded by protein coat	Viruses
Prokaryotic	- Simple structure - Single chromosome, no nucleus - No organelles	Bacteria
Eukaryotic	- Highly structured - Nucleus and cytoplasm - Organelles	Protozoans, fungi, parasites

the two bacteria belong to the same genus, they differ greatly in their ability to cause disease. The first letter of the genus is always capitalized and the species name is always written in all lowercase letters.

Viruses

LO 46.4

Viruses, which are among the smallest known infectious agents and cannot be seen with a regular microscope, are the cause of many common illnesses and conditions seen frequently in the medical office. Table 46-3 lists common viral pathogens. Because viruses are a simpler life form than the cell (see Figure 46-1), they can live and grow only within the living cells of other organisms.

Significant Viral Bloodborne Pathogens

In the medical office, you will likely encounter patients who are living with HIV and hepatitis. As you learned in the *Infection Control Fundamentals* chapter, proper technique is essential when handling blood and body fluids. You also must understand how HIV and hepatitis cause infection, and how to recognize the symptoms of each disease.

AIDS/HIV Infection HIV is a virus that infects and gradually destroys components of the immune system. AIDS is the condition that results from the advanced stages of this viral infection.

Over a period of time and in most cases, HIV infection develops into AIDS, which results in death. The pathogen gradually destroys helper T cells. *Helper T cells* are white blood cells that are a key component of the body's immune system, working in coordination with other white blood cells (B cells, macrophages, and so on) to combat infection.

The virus also attacks neurons, causing demyelination (destruction of the myelin sheath of a nerve), which results in neurologic problems, including dementia. Unlike a person with a properly functioning immune system, most AIDS patients are prone to various opportunistic infections—infections caused by microorganisms that do not ordinarily cause disease in people with properly functioning immune systems. Virtually everyone is at risk for contracting HIV. Although its initial outbreak in the United States appeared in the male homosexual population, and currently homosexual and bisexual men make up a large percentage of AIDS cases, the disease knows no limits.

Symptoms HIV infection can cause a variety of problems as it progresses to AIDS. Patients with AIDS may complain of any of the following symptoms:

- Systemic complaints, such as weight loss, fatigue, fever, chills, and night sweats
- Respiratory complaints, such as sinus fullness, dry cough, shortness of breath, difficulty swallowing, and sinus drainage
- Oral complaints, such as gingivitis, oral lesions, and hairy leukoplakia, which is a white lesion on the tongue
- Gastrointestinal complaints, such as diarrhea and bloody stool
- Central nervous system (CNS) complaints, such as depression, personality changes, concentration difficulties, and confusion or memory loss
- Peripheral nervous system complaints, such as tingling, numbness, pain, and weakness in the extremities
- Skin-related complaints, such as rashes, dry skin, and changes in the nail bed
- Kaposi's sarcoma, an unusual malignancy occurring in the skin and sometimes in the lymph nodes and organs and manifested by reddish purple to dark blue patches or spots on the skin

TABLE 46-3 Viral Pathogens

Disease	Causative Organism	Route of Transmission	Signs and Symptoms
Viral pharyngitis	Adenovirus	Direct person-to-person contact and respiratory droplet contact	Colds, pharyngitis, bronchitis, pneumonia, diarrhea, pink eye, fever, cystitis, gastroenteritis, and/or neurologic disease
Infectious mononucleosis	Epstein-Barr virus	Direct contact with saliva from an infected person	Fever, sore throat, and swollen lymph glands
Hepatitis	Hepatitis A virus	Fecal-oral	Fever, fatigue, loss of appetite, nausea, vomiting, abdominal pain, dark urine, clay-colored bowel movements, joint pain, and jaundice
	Hepatitis B virus	Bloodborne, sexually transmitted infection (STI)	
	Hepatitis C virus	Bloodborne	
Cold sores	Herpes simplex virus, type 1	Direct contact with someone infected with <i>Herpes simplex</i> , type 1 (sharing eating utensils or drinking glasses, kissing)	Pain; tingling; small, painful, fluid-filled blisters on a raised, red area of the skin, typically around the mouth
Genital herpes	Herpes simplex virus, type 2	STI	Pain, itching, small red bumps, blisters, and ulcers
CMV	Cytomegalovirus	Direct contact, maternal-fetal transmission	Healthy adults: usually asymptomatic but may have mild hepatitis and prolonged fever Congenital: premature birth, liver problems, lung problems, spleen problems, small size at birth, small head size, seizures, hearing loss, vision loss, lack of coordination, and/or mental disability
AIDS	HIV	Bloodborne, STI	Initial: flu-like symptoms Untreated or advanced: heart, kidney, and liver disease; cancer; and opportunistic infections
Influenza	Influenza virus	Airborne, respiratory droplets	Fever, cough, sore throat, runny or stuffy nose, muscle or body aches, headaches, and fatigue
Measles	Measles virus	Airborne, respiratory droplets	Blotchy rash, fever, cough, runny nose, conjunctivitis, malaise, and tiny white spots with bluish-white centers inside the mouth
Mumps	Mumps virus	Airborne, respiratory droplets	Fever, headache, muscle aches, fatigue, loss of appetite, and swollen and tender salivary (parotid) glands
HPV infection	Human papillomavirus	STI	The majority of cases are asymptomatic; some strains cause genital warts; others are associated with cervical cancer
Upper respiratory infections, viral	Parainfluenza virus	Direct contact with respiratory secretions (droplets)	HPV1: croup HPV3: bronchiolitis and pneumonia
Polio	Poliovirus	Direct person-to-person contact	Fever, fatigue, nausea, headache, flu-like symptoms, back and neck stiffness, limb pain, and/or paralysis
Rabies	Rabies virus	Direct contact with saliva of rabid animal, usually through the bite of an infected animal	Initially: weakness, fever, and headache If untreated: cerebral dysfunction, anxiety, confusion, agitation, delirium, abnormal behavior, hallucinations, insomnia, and death
Norovirus infection, acute gastroenteritis	Norovirus	Fecal-oral; foodborne (most common cause of foodborne illness in the United States)	Diarrhea, nausea, stomach pain, vomiting, fever, headache, and body aches
Rotavirus infection	Rotavirus	Fecal-oral	Fever, diarrhea, abdominal pain, and vomiting
Fifth disease	Parvovirus B19	Direct contact with respiratory secretions (droplets); can be spread through blood or blood products	Fever, runny nose, headache, rash on face (slapped cheek appearance) and body, and arthralgia

(Continued)

TABLE 46-3 Viral Pathogens

Disease	Causative Organism	Route of Transmission	Signs and Symptoms
RSV	Respiratory syncytial virus	Airborne, respiratory secretions (droplets)	Cough, sneezing, runny nose, fever, loss of appetite, wheezing, and dyspnea
German measles (3-day measles)	Rubella virus	Airborne, respiratory secretions (droplets)	Fever and rash; if acquired during pregnancy, fetal symptoms may include deafness, cataracts, heart defects, mental retardation, and liver and spleen damage
Chickenpox	Varicella-zoster virus	Direct contact with respiratory secretions (droplets); airborne, respiratory secretions (droplets)	High fever, fatigue, loss of appetite, headache, and itchy rash that becomes blistered, then scabs over

Because many other diseases can cause these symptoms, the occurrence of any one symptom is not necessarily indicative of AIDS. Be aware, however, that patients exhibiting a combination of symptoms should be tested. The two symptoms most indicative of AIDS are hairy leukoplakia and Kaposi's sarcoma.

Chronic Disorders of the AIDS Patient The impaired immune system of the AIDS patient permits opportunistic infections, which further reduce the body's ability to fight off infection. These infections attack many different parts of the body.

One of the cornerstones of the care of patients who have AIDS is to prevent opportunistic infections and identify such infections as quickly as possible when they occur. Identifying malignancies, if they occur, is also of utmost importance. If you are familiar with the common disorders an AIDS patient faces, you will be better able to identify early signs of infection or malignancy and point them out to the doctor, in turn initiating early treatment, which is usually most effective. You can help patients who have been diagnosed with HIV to understand the risks they face and the measures best suited to preventing particular infections. Opportunistic infections and chronic disorders include:

- *Pneumocystis carinii* pneumonia
- Kaposi's sarcoma
- Non-Hodgkin's lymphoma
- Tuberculosis
- *Mycobacterium avium* complex (MAC) infection
- Meningitis
- Oral candidiasis
- Vaginal candidiasis
- Herpes simplex
- Herpes zoster

Hepatitis Hepatitis is a viral infection of the liver that can lead to cirrhosis and death. Hepatitis virus variants differ in their means of transmission and in their presenting symptoms of infection. Those variations commonly transmitted through the bloodborne route include the following:

- Hepatitis B is the most common bloodborne hazard health-care workers face. It is spread through contact with contaminated blood or body fluids and through sexual contact.

Most patients recover fully from hepatitis B virus (HBV) infection, but some patients develop chronic infection or remain carriers of the pathogen for the rest of their lives. Adults and children with hepatitis B who develop lifelong infections may experience serious health problems, including cirrhosis (scarring of the liver), liver cancer, liver failure, and death. Preventing the spread of the infection is the most effective means of combating the disease. Following standard precautions and receiving HBV vaccinations are the most effective ways to control the spread of the infection.

- Hepatitis C is also spread through contact with contaminated blood or body fluids and through sexual contact. There is no cure for this variant, which has resulted in more deaths than hepatitis A and hepatitis B combined. Many people become carriers of hepatitis C without knowing it because they do not experience any symptoms. If the infection causes immediate symptoms, they often resemble the flu. Although treatment exists to suppress the virus, nothing can prevent or stop the virus from replicating. Over time, it is likely to damage the liver, causing cirrhosis, liver failure, and cancer. As with hepatitis B, preventing the spread of the infection is the best way to combat the disease.
- Hepatitis D (delta agent hepatitis) occurs only in people infected with HBV. Delta agent infection may make hepatitis B symptoms more severe, and it is associated with liver cancer. The HBV vaccine also prevents delta agent infection.

Symptoms People infected with hepatitis may show no symptoms, may experience such mild or subtle symptoms that they do not realize they are seriously ill, or may experience severe symptoms. When you treat patients with hepatitis, any of these signs and symptoms may be present:

- Jaundice (Figure 46-2)
- Diminished appetite
- Fatigue
- Nausea
- Vomiting
- Joint pain or tenderness
- Stomach pain
- General malaise

FIGURE 46-2 Jaundice is caused by excess bilirubin, which is produced in the liver and deposited throughout the body, resulting in the yellow appearance of the patient's eyes and skin.
CDC

Bacteria

LO 46.5

Bacteria are single-celled prokaryotic (without a nucleus) organisms that reproduce very quickly and are one of the major causes of disease. Under the right conditions—the right temperature, the right nutrients, and moisture—bacterial cells can double in number in 15 to 30 minutes. This rapid reproduction is one reason that untreated infections can be dangerous.

Classification and Identification

Bacteria can be classified according to their shape, their ability to retain certain dyes, their ability to grow with or without air, and certain biochemical reactions.

Shape The most common way to classify bacteria is according to their shape. The four common shape classifications are the coccus, bacillus, spirillum, and vibrio (see Figure 46-3).

A **coccus** (plural, *cocci*) is spherical, round, or ovoid. Cocci can be further divided into three types:

- *Staphylococci* are grape-like clusters of cocci commonly found on the skin (*staphylo* means “cluster of grapes”). One species of this microorganism causes a variety of infections, including boils, acne, abscesses, food poisoning, and a type of pneumonia. When viewed under a microscope, stained staphylococci look like clusters of purple grapes.
- *Diplococci* are pairs of cocci (*diplo-* means “double”). The causative agents for gonorrhea and some forms of meningitis are diplococci. When viewed under a microscope, stained diplococci are said to look like little boxing gloves.
- *Streptococci* are cocci that grow in chains (*strepto-* means “twisted chain”). These microorganisms are responsible for infections such as strep throat, certain types of pneumonia, and rheumatic fever. When viewed under the microscope, stained streptococci look like long chains of round beads.

(a)

(c)

(b)

(d)

FIGURE 46-3 The four bacterial classifications by shape are (a) coccus, (b) bacillus, (c) spirillum, and (d) vibrio.

(a) © CDC/Janice Carr; (b) CDC/Janice Carr; (c) © Melba Photo Agency/Punchstock RF; (d) © Janice Carr/CDC

A **bacillus** (plural, *bacilli*) is rod-shaped (*bacillo-* is derived from the Latin word meaning “stick”). Bacilli are responsible for a wide variety of infections, including gastroenteritis, tuberculosis, pneumonia, whooping cough, urinary tract infections (UTIs), botulism, and tetanus. When viewed under the microscope, stained bacilli look like little rods or rounded sticks.

A **spirillum** (plural, *spirilla*) is spiral-shaped (*spira-* means “coil”). Spirilla are responsible for infections such as syphilis and Lyme disease. When viewed under a microscope, stained spirilla look like stretched-out springs or coils.

A **vibrio** (plural, *vibrios*) is comma-shaped (*vibrio* means “vibrate”). Most vibrio bacteria are found in water and are motile, meaning that they move. Vibrios are responsible for diseases such as cholera and some cases of food poisoning. When viewed under a microscope, stained vibrios look like commas or hooked structures.

Ability to Retain Certain Dyes In addition to their shape, bacteria are commonly classified by how they react to certain stains. A **stain** is a specific dye or group of dyes that imparts a color to microorganisms. The most common staining procedure in use today is the **Gram stain**. This method of staining uses a group of dyes and decolorizers to differentiate bacteria according to the chemical composition of their cell walls. Gram staining techniques separate bacteria into two groups, **Gram-positive** and **Gram-negative**. Gram-positive bacteria retain the crystal violet stain during the staining process causing them to appear blue when viewed under the microscope. Gram-negative bacteria do not retain the crystal violet stain during the staining process however, they do take up the red counter stain. This causes them to appear red when viewed under the microscope. The **acid-fast stain** is a staining procedure for identifying bacteria with a waxy cell wall. The bacteria that cause tuberculosis have waxy cell walls and can be stained with this procedure.

Ability to Grow in the Presence or Absence of Air Bacteria that grow best in the presence of oxygen are referred to as **aerobes**. Those that grow best in the absence of oxygen are referred to as **anaerobes**. Organisms that can grow in either environment are referred to as **facultative**. Although most common bacteria are aerobes, many of the bacteria that make up the body’s resident normal flora are anaerobes. Not surprisingly, anaerobes are often responsible for infections within the body.

Biochemical Reactions Many closely related bacteria can be differentiated from one another only by certain biochemical reactions that occur within the bacterial cell. For example, one way to identify a particular bacterial strain is to look at what types of sugars the bacteria can grow on.

Special Groups of Bacteria

Several groups of bacteria have certain characteristics that set them apart from most other bacteria. These include the mycobacteria, rickettsiae, chlamydiae, and mycoplasmas.

Mycobacteria Mycobacteria are rod-shaped bacilli with a waxy cell wall, making them acid-fast. Certain types of mycobacteria cause disease in humans. For example, *Mycobacterium tuberculosis* causes the respiratory disease tuberculosis and *Mycobacterium leprae* causes leprosy, also known as Hansen’s disease.

Rickettsiae Rickettsiae are unusually small bacteria that can live and grow only within other living cells. Rickettsiae are commonly found in insects like ticks and mites but may be transmitted to humans through bites. Rickettsiae are responsible for diseases such as Rocky Mountain spotted fever and typhus.

Chlamydiae Chlamydiae differ from other bacteria in the structure of their cell walls. Like rickettsiae, they can live and grow only within other living cells. In humans, chlamydiae can cause sexually transmitted infections (STIs), eye disease, certain types of pneumonia, and certain types of heart disease.

Mycoplasmas Mycoplasmas are unusually small bacteria that completely lack the rigid cell wall of other bacteria. These bacteria cause a variety of human diseases, including STIs and a form of pneumonia.

Bacterial Pathogens

In spite of our efforts to eradicate disease-causing bacteria through the use of antibiotics, bacterial pathogens are still with us. Table 46-4 lists some of these pathogens and the diseases they cause.

Drug-Resistant Microorganisms

Drug-resistant pathogens are the cause of many infections. Drug resistance has been linked to overuse of antibiotics. It is the responsibility of physicians, medical staff, and patients to use antibiotics wisely, as resistance to antimicrobial agents is a severe problem. Bacteria and other microorganisms that have developed resistance to antimicrobial drugs include the following:

- MRSA—methicillin/oxacillin-resistant *S. aureus*
- VRE—vancomycin-resistant enterococci
- VISA—vancomycin-intermediate *S. aureus*
- VRSA—vancomycin-resistant *S. aureus*
- ESBLs—extended-spectrum beta-lactamases, which are resistant to cephalosporins and monobactams
- PRSP—penicillin-resistant *Streptococcus pneumoniae*

MRSA and VRE are the most common multidrug-resistant organisms in patients who reside in nonhospital healthcare facilities (for example, nursing homes and other long-term care facilities). People outside of healthcare facilities are increasingly at risk for MRSA, as community-associated MRSA, an infection found in otherwise healthy individuals, is on the rise in the United States. PRSP is more common in patients seeking care in physicians’ offices and clinics, especially in pediatric settings. This is thought to be because penicillin is the most commonly prescribed antibiotic in outpatient settings.

TABLE 46-4 Bacterial Pathogens

Disease	Causative Organism	Characteristics	Route of Transmission	Signs and Symptoms
Anthrax	<i>Bacillus anthracis</i>	Aerobic, Gram-positive, spore-forming bacillus	Contact with animals infected with or inhalation of <i>B. anthracis</i> spores, or consumption of raw or undercooked meat from infected animals	Cutaneous: raised, blistered skin lesion with development of black eschar (dead tissue) Inhalation: high fever, dyspnea, stridor, cyanosis, and shock
Whooping cough	<i>Bordetella pertussis</i>	Gram-negative bacterium	Airborne	Stage 1: runny nose, low-grade fever, and mild cough Stage 2: bursts of rapid, uncontrollable coughs with characteristic “whoops” at the end of the cough; cyanosis; and exhaustion Stage 3: recovery and less persistent cough
Lyme disease	<i>Borrelia burgdorferi</i>	Spirochete that does not have typical Gram stain characteristics	Tick-borne (Ixodes tick)	Red, expanding, “bull’s-eye” rash; fatigue; fever; chills; headache; muscle and joint aches; and swollen lymph nodes
Campylobacteriosis	<i>Campylobacter jejuni</i>	Gram-negative, microaerophilic, spiral-shaped	Fecal-oral, foodborne	Diarrhea, sometimes bloody; abdominal cramps; and fever
Chlamydia	<i>Chlamydia trachomatis</i>	Coccus; does not have typical Gram stain characteristics but is considered Gram-negative; obligate, intracellular bacteria (must live within an animal cell)	STI	Women: often “silent”; possible vaginal discharge and dysuria Men: penile discharge and dysuria
Botulism	<i>Clostridium botulinum</i>	Anaerobic, Gram-positive, spore-forming bacillus	Foodborne	Double vision, blurred vision, drooping eyelids, slurred speech, difficulty swallowing, dry mouth, and muscle weakness
Pseudomembranous colitis	<i>Clostridium difficile</i>	Anaerobic, Gram-positive, spore-forming bacillus	Fecal-oral (healthcare-associated infection)	Watery diarrhea, fever, loss of appetite, nausea, and abdominal pain/tenderness
Tetanus	<i>Clostridium tetani</i>	Anaerobic, Gram-positive bacillus (sometimes forms spores)	Direct contact through a deep cut	Early: lockjaw, neck and abdomen stiffness, and difficulty swallowing Late: severe muscle spasms and generalized tonic-seizure-like activity
Diphtheria	<i>Corynebacterium diphtheria</i>	Gram-positive bacillus	Direct person-to-person contact with respiratory droplets or cutaneous lesions	Sore throat; low-grade fever; and presence of a pseudomembrane over the tonsils, throat, and nose
<i>E. coli</i> diarrhea	<i>Escherichia coli</i>	Gram-negative bacillus	Foodborne (some strains do not cause disease)	Diarrhea, severe abdominal cramps, and vomiting
<i>Haemophilus influenzae</i> Serotype b (Hib) disease (epiglottitis, pneumonia)	<i>Haemophilus influenzae</i>	Gram-negative coccobacillus	Direct contact with respiratory droplets	Epiglottitis: sore throat and difficulty breathing Pneumonia: difficulty breathing and fever
Peptic ulcer	<i>Helicobacter pylori</i>	Microaerophilic, Gram-negative bacillus	Not well understood; may be fecal-oral or oral-oral	Gnawing or burning stomach pain, nausea, bloating, and burping
Legionnaire’s disease	<i>Legionella pneumophila</i>	Gram-negative bacillus	Water aerosol	High fever, chills, cough, chest pain, and pneumonia

(Continued)

TABLE 46-4 Bacterial Pathogens

Disease	Causative Organism	Characteristics	Route of Transmission	Signs and Symptoms
Leprosy	<i>Mycobacterium leprae</i>	Acid-fast bacillus	Airborne, respiratory droplets	Skin lesions, nodules, plaques, and thickened dermis
Tuberculosis	<i>Mycobacterium tuberculosis</i>	Acid-fast bacillus	Airborne, respiratory droplets	Bad cough lasting 3 weeks or longer, pain in the chest, coughing up blood or sputum, weakness or fatigue, weight loss, no appetite, chills, fever, and night sweats
Mycoplasma pneumonia	<i>Mycoplasma pneumoniae</i>	Wall-less bacteria, usually coccoid in shape with polar extensions	Direct contact with respiratory droplets	Fever, nonproductive cough, malaise, and headache
Gonorrhea	<i>Neisseria gonorrhoeae</i>	Gram-negative diplococcus	STI	Women: most have no symptoms; some have dysuria and vaginal discharge Men: dysuria and green, yellow, or white penile discharge Left untreated can cause complications in both women and men
Meningitis	<i>Neisseria meningitidis</i>	Gram-negative diplococcus	Direct contact with respiratory droplets	Stiff neck, fever, confusion, light sensitivity, nausea, and vomiting
	<i>Haemophilus influenzae</i>	Gram-negative coccobacillus		
	Group B <i>Streptococcus</i> (<i>Streptococcus agalactiae</i>)	Gram-positive coccus		
	<i>Listeria monocytogenes</i>	Gram-positive, flagellated bacillus		
Pseudomonas infection (hot tub rash)	<i>Pseudomonas aeruginosa</i>	Gram-negative bacillus	Direct contact with water contaminated with <i>P. aeruginosa</i>	Itchy, red rash and pustules around hair follicles
Rocky Mountain spotted fever	<i>Rickettsia rickettsi</i>	Gram-negative coccobacillus	Tick-borne (wood or dog tick)	Fever, rash (occurs 2–5 days after fever), headache, nausea, vomiting, abdominal pain, muscle pain, lack of appetite, and conjunctival inflammation
Shigellosis	<i>Shigella sonnei</i>	Gram-negative bacillus	Fecal-oral	Diarrhea, fever, and stomach cramps
Methicillin-resistant <i>Staphylococcus aureus</i> (MRSA) infection	<i>Staphylococcus aureus</i>	Gram-positive coccus	Direct contact	Red, swollen, painful pustules
Bacterial pneumonia	<i>Streptococcus pneumonia</i>	Gram-positive diplococcus	Direct person-to-person contact	Cough, chest pain, shortness of breath, malaise, and poor appetite
Strep throat	<i>Streptococcus pyogenes</i>	Gram-positive coccus	Direct contact with respiratory droplets	Sore throat and fever
Syphilis	<i>Treponema pallidum</i>	Gram-negative spirochete	STI	Primary stage: single sore (chancre) at site of the organism's entry into the body Secondary stage: skin rash and mucous membrane lesions Late stage: uncoordinated muscle movements, paralysis, numbness, gradual blindness, and dementia
Cholera	<i>Vibrio cholerae</i>	Gram-negative curved rod	Fecal-oral from contaminated water	Profuse watery diarrhea ("rice-water stools"), vomiting, rapid heart rate, loss of skin elasticity, dry mucous membranes, low blood pressure, thirst, muscle cramps, and restlessness or irritability

Risk Factors

There are a number of risk factors for both the development of and infection with drug-resistant organisms. These risk factors include:

- Advanced age
- Invasive procedures, which include dialysis, the presence of invasive devices, and urinary catheterization
- Previous use of antimicrobial agents
- Repeated contact with the healthcare system
- Severity of the illness
- Underlying diseases or conditions, especially chronic renal disease, insulin-dependent diabetes mellitus, peripheral vascular disease, and dermatitis or skin lesions

Preventing Antibiotic Resistance in Healthcare Settings

In response to a growing concern over the emergence of antibiotic-resistant infections, the CDC began the Campaign to Prevent Antimicrobial Resistance in Healthcare Settings. This campaign has four strategies to reduce the incidence of antibiotic-resistant microorganisms:

- Prevent infection
- Diagnose and treat infection appropriately
- Use antibiotics carefully
- Prevent transmission of infections

Protozoans

LO 46.6

Protozoans are single-celled eukaryotic (with a nucleus) organisms that are generally much larger than bacteria. Found in soil and water, most do not cause disease in people. Certain protozoans are pathogenic, however, and cause diseases such as malaria, amebic dysentery (a type of diarrhea), and trichomoniasis vaginitis (a type of STI; see Figure 46-4). Protozoal diseases are a leading cause of death in developing countries because the lack of proper sanitation in some areas promotes their spread. These diseases are also common in patients with depressed immune systems. Table 46-5 lists some of the parasitic protozoans and multicellular parasites that affect humans.

FIGURE 46-4 The protozoan *Trichomonas vaginalis* causes a common STI in humans.

© Melba Photo Agency/Punchstock RF

TABLE 46-5 Human Protozoal and Multicellular Parasites

Disease	Causative Organism	Notable Features	Route of Transmission	Signs and Symptoms
Intestinal				
Amebiasis	<i>Entamoeba histolytica</i>	Can become invasive and cause liver abscess	Fecal-oral	Loose stool, abdominal pain, abdominal cramping, bloody diarrhea, and fever
Intestinal hookworm	<i>Necator americanus</i> and <i>Ancylostoma duodenale</i>	Larvae migrate to the intestinal tract.	Larvae in soil contaminated with feces from an infected person penetrate bare feet and cause infection.	Itching at the site of entry, abdominal pain, diarrhea, anorexia, and anemia due to loss of blood at the site of attachment in the intestine
Round worm	<i>Ascaris lumbricoides</i>	Most common helminthic (worm) infection in the world	Contact with contaminated soil	Can be asymptomatic; symptoms include abdominal discomfort and intestinal blockage
Cryptosporidiosis	<i>Cryptosporidium parvum</i> and <i>C. hominis</i>	Can be found in recreational water such as swimming pools and hot tubs contaminated with <i>Cryptosporidium</i>	Waterborne	Abdominal cramps and pain, dehydration, nausea, vomiting, fever, and weight loss
Cyclosporiasis	<i>Cyclospora cayatanensis</i>	Outbreaks in the United States have been linked to imported fresh produce.	Fecal-oral	Frequent, explosive, watery diarrhea; abdominal cramps; loss of appetite; weight loss; bloating; excessive gas; and fatigue
Fish or broad tapeworm	<i>Diphyllobothrium latum</i>	Longest human tapeworm, reaching up to 30 feet in length	Foodborne from eating raw or undercooked fish infected with <i>D. latum</i>	Abdominal discomfort, diarrhea, vomiting, weight loss, and vitamin B ₁₂ deficiency
Pinworm	<i>Enterobius vermicularis</i>	While the infected person is sleeping, female pinworms leave the intestine and lay their eggs on the skin surrounding the anus.	Fecal-oral	Anal itching, and nighttime restlessness due to anal itching

(Continued)

TABLE 46-5 Human Protozoal and Multicellular Parasites

Disease	Causative Organism	Notable Features	Route of Transmission	Signs and Symptoms
Giardiasis	<i>Giardia intestinalis</i> (formerly <i>G. lamblia</i>)	Once outside the body, can live in soil or water for weeks or months	Fecal-oral	Greasy, floating stool; gas; diarrhea; abdominal pain and cramping; nausea; and dehydration
Lung fluke (Paragonimiasis)	<i>Paragonimus kellicotti</i>	Linked to eating raw or undercooked crab or crayfish infected with <i>P. kellicotti</i> ; ingested larvae migrate to the lungs	Foodborne	Initially diarrhea and abdominal pain, followed by fever, chest pain, fatigue, and cough
Bloodborne/Vector-borne				
Chagas disease	<i>Trypanosome cruzi</i>	Found only in the Americas (mostly Latin America but also the United States)	Vector-borne (triatomine bug)	Acute phase: fever, fatigue, body aches, headache, and diarrhea Chronic phase: cardiomyopathy, heart failure, heart arrhythmia, enlarged esophagus, enlarged colon, and difficulty eating or passing stool
Malaria	<i>Plasmodium falciparum</i> , <i>P. vivax</i> , <i>P. ovale</i> , <i>P. malariae</i>	Fifth most common cause of death worldwide from infectious disease	Vector-borne (mosquito)	Fever, chills, sweats, headache, nausea, body aches, and general malaise
Skin				
Swimmer's itch (cercarial dermatitis)	<i>Austrobilharzia variglandis</i>	Ducks and geese are the most common host; however, the larvae will burrow into a human swimmer's skin.	Contact with larvae in water	Tingling, burning, or itching of the skin; small, reddish pimples; and small blisters
Head lice (pediculosis)	<i>Pediculus humanus capitis</i>	Can be transmitted by contact with clothing, combs, or brushes used by an infested individual	Direct contact with the hair of infested individual	Feeling that something is moving in your hair, itching, difficulty sleeping because of louse activity, and scalp sores
Pubic lice (phthiriasis)	<i>Phthirus pubis</i>	Infestation has been linked to casual contact with personal items—like combs or hairbrushes—used by infested individuals.	Direct contact with an infested individual (usually sexual contact)	Genital itching, visible nits (eggs), or crawling adult lice
Scabies	<i>Sarcoptes scabiei</i>	Symptoms worse at night	Prolonged, direct contact with an infested individual	Intense itching and papular rash
Bed bugs	<i>Cimex lectularius</i> and <i>C. hemipterus</i>	Not known to carry any disease and not considered a public health threat	Exposure to bedding or furniture infested with <i>C. lectularius</i> or <i>C. hemipterus</i>	Bite marks on the head, neck, face, hands, or other body parts occurring at night while sleeping
Muscle				
Trichinellosis	<i>Trichinella spiralis</i>	Currently uncommon in commercial pork; more cases in the United States are now associated with wild game.	Foodborne from eating raw or undercooked pork or wild animals	Nausea, diarrhea, vomiting, fatigue, fever, abdominal pain, headache, chills, coughing, eye swelling, and joint pain
Toxoplasmosis	<i>Toxoplasma gondii</i>	Forms cysts that may be found in skeletal muscle, myocardium, brain, and eyes	Foodborne, animal-to-human, mother-to-child (congenital)	Some have no or very mild symptoms; swollen lymph glands and muscle aches
Vagina, Vulva, Urethra				
Trichomoniasis	<i>Trichomonas vaginalis</i>	Considered the most common and most curable STI	Sexual contact	Women: itching, burning, redness or soreness of the genitals, dysuria, and watery discharge with an unusual smell Men: itching or irritation inside the penis, burning after urination or ejaculation, and some penile discharge

(a)

(b)

FIGURE 46-5 Because fungi lack the ability to make their own food, they depend on other life forms. (a) Single-celled fungi are called yeasts. (b) Multicelled fungi are called molds.

Fungi

LO 46.7

A *fungus* (plural, *fungi*) is a eukaryotic organism that has a rigid cell wall at some stage in the life cycle. Fungi that grow mainly as single-celled organisms and reproduce by budding are referred to as *yeasts*, whereas fungi that grow into large, fuzzy, multicelled organisms that produce spores are called *molds*. Figure 46-5 shows the differences between these two types of fungi.

Most fungi do not cause disease in humans. Of those that do, the majority produce superficial infections such as athlete's foot (tinea pedis), ringworm, thrush, and vaginal yeast infections. Fungi can produce serious, life-threatening illness, however, when they infect the internal tissues. This kind of infection can occur when patients have a depressed immune system, as in patients who are undergoing cancer treatment and patients with AIDS. Table 46-6 lists some of the most common fungal diseases and the organisms that cause them.

Multicellular Parasites

LO 46.8

A *parasite* is an organism that lives on or in another organism and uses that other organism for food, or for some other advantage, to the detriment of the host organism. For example, a leech is a type of parasite that lives off of the host's blood. Viruses, rickettsiae, chlamydiae, and some protozoans are parasitic. Multicellular organisms also can be parasitic, and some of these organisms are microscopic during all or part of their lives. An infection caused by a parasite is called an *infestation*. Multicellular parasites that cause human disease include certain worms and insects, as illustrated in Figure 46-6 and listed in Table 46-5.

TABLE 46-6 Pathogenic Fungi

Disease	Causative Organism	Route of Transmission	Signs and Symptoms
Aspergillosis	<i>Aspergillus fumigatus</i> and <i>A. flavus</i>	Airborne (inhalation of spores)	Wheezing, coughing, fever, chest pain, shortness of breath, and aspergilloma (fungus ball)
Blastomycosis	<i>Blastomyces dermatitidis</i>	Airborne (inhalation of spores)	Fever, chills, cough, muscle aches, joint pain, and chest pain
Candidiasis • Oropharyngeal (thrush) • Vaginal • Invasive	<i>Candida albicans</i>	<i>C. albicans</i> is part of the body's resident normal flora; conditions that cause an imbalance in the resident normal flora cause an overgrowth of the fungus.	• Oropharyngeal—white patches on the tongue and other oral mucous membranes, redness or soreness in the affected areas, difficulty swallowing, and cracking at the corners of the mouth • Vaginal—genital itching; burning; and thick, white vaginal discharge • Invasive—fever and chills
Coccidioidomycosis (valley fever)	<i>Coccidioides</i>	Airborne (inhalation of spores)	Fever, cough, headache, rash on upper trunk or extremities, muscle aches, joint pain in the knees or ankles, skin lesions, chronic pneumonia, meningitis, and bone or joint infection
Ringworm	Dermatophytes (<i>Trichophyton rubrum</i> and <i>T. tonsurans</i>)	Direct contact with an infected person	Redness, scaling, cracking of the skin, or a ring-shaped rash; loss of hair at the site of infection

(Continued)

TABLE 46-6 Pathogenic Fungi			
Disease	Causative Organism	Route of Transmission	Signs and Symptoms
Cryptococcosis	<i>Cryptococcus neoformans</i> and <i>C. gattii</i>	Airborne; <i>C. neoformans</i> is usually associated with large amounts of bird droppings.	Shortness of breath, cough, fatigue, fever, headache, and meningitis
Histoplasmosis	<i>Histoplasma capsulatum</i>	Airborne, usually associated with large amounts of bird or bat droppings	Fever, chest pains, and nonproductive cough
Pneumocystis pneumonia (PCP)	<i>Pneumocystis jirovecii</i>	Airborne, inhalation of spores; most common opportunistic infection in people with HIV/AIDS	Fever, dry cough, shortness of breath, and fatigue
Sporotrichosis	<i>Sporothrix schenckii</i>	Direct contact with spores	Small, painless nodule at contact site; lesion becomes larger over time and may ulcerate

Parasitic Worms

People can be infested with a parasitic worm by ingesting its eggs or an immature form of the worm or by having the parasite penetrate the skin. As with the protozoans, infestation by these parasites is more common in developing nations with poor sanitation.

Worms that infect people include roundworms, flatworms, and tapeworms. Roundworms can occur in the intestines, as in the case of pinworms, a common infection in children. Other roundworms, such as *Trichinella*, are found in muscle tissue. *Trichinella spiralis*, which causes the infection trichinosis, enters the human body in infected meat eaten raw or

FIGURE 46-6 Parasitic worms, such as (a) tapeworms (Cestoda) and (b) *Trichinella*, cause disease in humans when they are ingested. Parasitic insects, such as (c) mosquitoes, (d) deer ticks, and (e) mites, cause disease by biting or burrowing into the skin.
 (a) CDC; (b) © Dickson Despommier/Science Source; (c) CDC/James Gathany; (d) © The Image Bank/Getty Images; (e) © Photo by Scott Bauer/USDA

insufficiently cooked. People also may get flatworms and tapeworms by eating undercooked meats. A trained medical professional must inspect a patient's stool for the presence of the parasite or its eggs to diagnose an intestinal infection with a parasitic worm.

Parasitic Insects

Insects that can bite or burrow under the skin include mosquitoes, ticks, lice, and mites. These insects spread many viral, bacterial (including rickettsial), and protozoal diseases. The causative organisms can live in the insects' bodies and enter people's bodies when they are bitten by the insects. Such diseases include Lyme disease, malaria, Rocky Mountain spotted fever, and encephalitis. Lice are small insects that live on hair and skin and feed on blood. Scabies infestations are caused by mites that burrow under the skin.

► How Infections Are Diagnosed LO 46.9

To assist with the diagnosis and treatment of an infection, a medical assistant must work closely with other medical team members. The basic steps in diagnosis and treatment are summarized in Figure 46-7.

Step 1. Examine the Patient

When a patient comes in to the office with signs or symptoms that suggest an infection, begin by taking the patient's vital signs and noting the patient's complaints. On the basis of these findings and the patient examination, the doctor can make a presumptive, or tentative, clinical diagnosis.

In many cases, signs and symptoms of a particular infection are so characteristic of the disease that the doctor need not perform additional tests to reach a diagnosis. An example is a case of chickenpox or mumps. At other times, however, the doctor needs to gather additional information to confirm a diagnosis and determine the cause.

Step 2. Obtain One or More Specimens

To determine the cause of an infection, you may need to obtain specimens from one or more areas of the patient's body. Label each specimen properly and include with it the physician's presumptive diagnosis. If the sample is to be transported to an outside laboratory, ensure that it is transported in such a way that any pathogenic organisms remain alive (and safely contained) during transit.

Step 3. Examine the Specimen Directly

You must sometimes obtain more than one specimen from each site. The doctor or specially trained laboratory or microbiology personnel will then directly examine one specimen under the microscope. The specimen may be viewed in one of two ways:

- As a wet mount, a preparation of a specimen in a liquid that allows the organisms to remain alive and mobile while they are being identified
- As a smear, in which a specimen is spread thinly and evenly across a slide

If you make a smear, allow it to dry and then treat or stain it as ordered before it is examined microscopically. In some cases, direct examination allows the doctor to make a presumptive diagnosis of the microorganism.

Step 4. Culture the Specimen

If the physician still needs a more definitive identification of the microorganism, you may perform a **culture**, in which a sample of the specimen is placed in or on a substance that allows microorganisms to grow. A *culture medium* is a substance that contains all the nutrients a particular type of microorganism needs. Most media come in the form of a semisolid gel. After inoculating (placing a sample of the specimen in or on) the medium, it is placed in an incubator (a chamber that can be set to a specific temperature and humidity) to allow the microorganism to grow. This is often done by a laboratory technologist.

The culture is examined visually and microscopically after a specified time, and a preliminary identification is made. The physician sets up additional tests to confirm the identification of the microorganism that has been isolated from the specimen. Most microbiology laboratories and some physicians' office laboratories are equipped to grow routine bacterial cultures and some fungal cultures. Physicians' office laboratories, in particular, may have to send other types of cultures, such as virus cultures, to a specialized laboratory for identification.

Step 5. Determine the Culture's Antibiotic Sensitivity

In many cases of bacterial infection, a **culture and sensitivity (C&S)** is performed. This procedure involves culturing a specimen and then testing the isolated bacterium's susceptibility (sensitivity) to certain antibiotics. The results help the doctor determine which antibiotics might be most effective in treating the infection.

Step 6. Treat the Patient as Ordered by the Physician

On the basis of identification of the microorganism and antibiotic sensitivity, if determined, the physician can prescribe an *antimicrobial*. This agent, which kills microorganisms or suppresses their growth, should help clear up the patient's infection.

► Specimen Collection LO 46.10

Perhaps the most important step in isolating and identifying a microorganism as the cause of an infection is collecting the specimen. If this is done incorrectly, the organism may not grow in culture in a way that it can be identified, resulting in an untreated infection. Furthermore, if the specimen becomes contaminated during collection and the contaminant is mistakenly identified as the cause of the infection, the patient may receive incorrect or even harmful therapy.

In addition to vaginal specimens (discussed in detail in the *Assisting in Reproductive and Urinary Specialties* chapter), the most common types of culture specimens involve the following:

- Throat
- Urine

(a)

(b)

(c)

(d)

(e)

Specimen-Collection Devices

To help ensure optimal recovery of microorganisms, you must use the appropriate collection device and specimen container. Specimen-collection devices are available for the collection of sputum, urine, and stool specimens, as shown in Figure 46-8. These containers are designed with large openings to allow specimen collection with minimal chance of contamination. They also have tight-fitting caps to prevent leakage and contamination.

Sterile Swabs The most common device for obtaining cultures is the sterile swab. Sterile swabs vary in the absorbent material at the tip and in the composition of the shaft (Figure 46-9).

Although cotton is absorbent, it is no longer used for culture swabs because natural chemicals in cotton inhibit the growth of certain microorganisms. Polyester, rayon, or calcium alginate fibers are preferred. Most swabs used to collect routine specimens have a wooden or plastic shaft for rigidity. Swabs with a small tip and a flexible wire shaft are made especially for culturing hard-to-reach areas and obtaining pediatric specimens. Some collection containers contain two swabs—one for a culture and one for a smear.

Collection and Transport Systems

Sterile, self-contained systems for obtaining and transporting specimens are commercially available from many suppliers. The CULTURETTE Collection and Transport System, manufactured by Becton Dickinson Microbiology Systems of

FIGURE 46-9 Sterile swabs vary in size and material.

© Cliff Moore

Sparks, Maryland, is a well-known example. The unit, shown in Figure 46-10, contains a polyester swab and a small, thin-walled vial of transport medium in a plastic sleeve. If a specimen will not be tested within 30 minutes after it is obtained, the swab is replaced in the sleeve and the vial is crushed between the thumb and the index finger. The moisture and nutrients provided by the transport medium help keep the bacteria alive during transport to the laboratory.

Several collection systems are also available for culturing anaerobic organisms. These systems provide a means of generating an oxygen-free environment so the anaerobic organisms remain viable (alive and able to reproduce) during transport.

Specimen-Collection Guidelines

To collect specimens properly, you should follow a number of general guidelines.

- Obtain the specimen with great care to avoid causing the patient harm, discomfort, or undue embarrassment. If patients are to collect specimens on their own, give them clear, detailed instructions along with the proper container.
- Collect the material from a site where the organism is most likely to be found and where contamination is least likely to occur. For example, the best location to obtain a specimen for diagnosing strep throat is at the back of the throat in the area of the tonsils. A properly collected sputum specimen should contain mucus coughed up from the respiratory tract but should not contain saliva, which is a contaminant.
- Obtain the specimen at a time that allows optimal chance of recovery of the microorganism. Knowledge of the infectious disease process allows the doctor to determine the best time to collect a specimen. For example, certain viruses are more readily isolated during the early, symptomatic stage of an illness.
- Use appropriate collection devices, specimen containers, transport systems, and culture media to ensure optimal microorganism recovery. The purpose of such equipment and materials is to preserve the viability of any microorganisms so that they will grow in culture. Special collection devices are available for certain body areas or suspected pathogens.

FIGURE 46-10 The CULTURETTE is used to obtain and transport microbiologic specimens to outside laboratories.

Source: Courtesy of Becton Dickinson Microbiology Systems.

© Cliff Moore

- Obtain a sufficient quantity of the specimen for performing the requested procedures. If, for example, both a culture and a direct examination of a swabbed specimen will be done, you must collect two specimens. Each procedure requires its own sample.
- Obtain the specimen before antimicrobial therapy begins. If the patient is already taking an antibiotic, note this fact on the laboratory request form or ask the doctor whether you should obtain the specimen.

After correctly collecting the specimen, you must label the container and include the appropriate requisition form. The label should contain the following information:

- Patient's name and identification number (if appropriate)
- Source (collection site) of the specimen
- Date and time of collection
- Doctor's name
- Your initials (if you obtained the specimen)

The requisition form should include the following information:

- Patient's name, address, and identification number
- Patient's age and gender
- Patient's insurance billing information
- Type and source of the microbiologic specimen (for example, discharge from wound, big toe)
- Date and time of microbiologic specimen collection
- Test requested
- Medications the patient is currently receiving
- Doctor's presumptive diagnosis
- Doctor's name, address, and phone number
- Special instructions or orders

Throat Culture Specimens

The doctor may request a throat culture on patients with signs or symptoms of an upper respiratory, throat, or sinus infection. In most cases, the doctor wants to determine whether the

patient has strep throat, an infection caused by the bacterium *Streptococcus pyogenes*, a group A streptococcus. It is particularly important to diagnose and treat this infection because, left untreated, strep throat can lead to complications such as rheumatic fever. Rheumatic fever is an inflammation of the heart tissue that occurs most frequently in school-age children.

When you obtain a throat culture specimen, avoid touching any structures inside the mouth, as this will contaminate the specimen. The correct technique for obtaining a throat culture specimen is outlined in Procedure 46-1 at the end of this chapter.

Many doctors order rapid strep tests if strep is suspected. Antigen-antibody test kits for strep are available in a variety of brands and provide immediate indications of the strep antigen's presence on a throat swab, sparing the patient the expense and waiting period associated with having a culture done. The correct technique for performing a rapid strep test is outlined in Procedure 46-2 at the end of this chapter.

If your office does not culture microbiologic specimens, use a sterile collection system to obtain the specimen. If your office has the equipment to perform its own cultures, use a sterile swab and inoculate a culture plate directly with the swab. Specimens to be evaluated in the office should be cultured immediately after collection.

Urine Specimens

To minimize contaminants in urine specimens, it is important to obtain a clean-catch mid-stream specimen. You must process urine specimens within an hour of collection or refrigerate them to prevent continued bacterial growth. (Collection of urine specimens for culturing is discussed in detail in the *Collecting, Processing, and Testing Urine and Stool Specimens* chapter.)

Sputum Specimens

To obtain sputum specimens, have the patient expectorate (cough up) mucus from the lungs into a wide-mouthed specimen container. Beforehand, instruct the patient to avoid contaminating the specimen with saliva. If sputum specimens are not cultured right away, they should be refrigerated.

Observe standard precautions whenever you handle sputum samples and wear a face shield or mask and goggles when collecting such specimens, especially if the patient is coughing. Even when tuberculosis is not suspected, the potential for its transmission always exists.

Wound Specimens

You usually obtain specimens from infected wounds and lesions by swabbing. The procedure is similar to that of a throat culture. Be sure you obtain representative material from a deep area and a surface area of the wound without contaminating the swab by touching areas outside the site.

► Transporting Specimens to an Outside Laboratory

LO 46.11

Many physicians' offices do not perform microbiologic testing on-site, choosing instead to send their culture specimens to an outside laboratory. This is particularly true for many specialized microbiologic procedures like virus cultures and bacteria cultures (including chlamydia) that require special techniques and equipment rarely found in a physician's office laboratory.

Your Main Objectives

When you collect and transport a microbiologic specimen to an outside laboratory, you have three main objectives:

1. Making sure proper collection procedures are followed, including using the proper collection device. Improperly handled specimens will not be processed at the lab.
2. Maintaining the samples in a state as close to their original as possible. You must take specific steps to prevent them from deteriorating.
3. Protecting anyone who handles a specimen container from exposure to potentially infectious material. To do so, ensure that the specimen container has a tight-fitting lid. As extra protection against leakage, place the specimen container in a secondary container or zipper-type plastic bag (usually provided by the laboratory).

Methods of Transportation

Specimens to be tested by an outside laboratory may be transported in one of three ways:

- During regularly scheduled daily pickups by the laboratory
- During an as-needed pickup by the laboratory
- Through the mail

Pickup by the laboratory is the most reliable and timely method of transporting microbiologic specimens. Although

each laboratory has its own procedure, the general steps for preparing specimens for transport to a laboratory are outlined in Procedure 46-3 at the end of this chapter.

Sending Specimens by Mail

There may be times when you must send a specimen through the mail to a special reference laboratory for a test not normally done by a local laboratory. The US Postal Service accepts a package containing microbiologic specimens as long as the total volume of specimen material is less than 50 milliliters and it is packaged under strict regulations specified by the US Public Health Service.

When sending specimens through the mail, pack them securely with adequate cushioning material to prevent breakage and leakage. Leakage can contaminate the specimen, putting mail handlers at risk of contamination with infectious materials. The proper technique for packaging and labeling microbiologic specimens is outlined by the Centers for Disease Control and Prevention (CDC) and is shown in Figure 46-11.

Securely close the primary culture container and surround it with enough absorbent packing material to absorb the entire fluid contents if the container were to leak. Place these items together in a secondary container, commonly a metal container with a screw-top or snap-on lid. Then place the secondary container in an outer shipping carton made of cardboard or Styrofoam®.

In addition to the address label, microbiologic specimens sent through the mail must have an etiologic agent label affixed to the package, as shown in Figure 46-11. This label uses the biohazard symbol to alert the mail carrier as to the nature of the contents. The term **etiologic agent** refers to a living microorganism or its toxin that may cause human disease.

► Direct Examination of Specimens LO 46.12

At times, the physician may directly examine the specimen under a microscope to detect the presence of microorganisms or to identify them. Two types of procedures that allow direct

FIGURE 46-11 When packaging and labeling a specimen for mail delivery, you must follow the procedures set by the CDC, based on US Public Health Service regulations.

examination of microbiologic specimens are preparing wet mounts and preparing potassium hydroxide (KOH) mounts. You may be required to perform these procedures as part of your duties.

Wet Mounts

A wet mount permits quick identification of many microorganisms and is easy to prepare.

1. Wearing examination gloves, mix a small amount of the specimen with a drop of normal saline (0.9% sodium chloride [NaCl] solution) on a glass slide.
2. Apply a coverslip over the mixture.
3. Give the slide to the doctor for direct examination under the microscope.

If you obtain a specimen from a body site that is normally sterile, detection of microorganisms on a wet mount immediately tells the doctor whether there is infection. Wet mounts are also useful in determining whether a microorganism is motile, which helps in identifying the microorganisms.

Potassium Hydroxide (KOH) Mounts

A **KOH mount** is a type of wet mount used when a physician suspects that a patient has a fungal infection of the skin, nails, hair, or vagina. It is difficult to visualize a fungus directly in these types of specimens because the body produces a tough, hard protein called keratin, which often masks any fungus present. The chemical potassium hydroxide (KOH) is added to the specimen to dissolve the keratin and allow visualization of any fungus.

To prepare a KOH mount, follow these steps:

1. Wearing examination gloves, suspend the specimen in a drop of 10% KOH on a glass slide.
2. Apply a coverslip.
3. Allow the specimen to sit at room temperature for 30 minutes to dissolve the keratin.
4. Provide the physician with the slide to examine for microscopic evidence of fungal structures.

► Preparation and Examination of Stained Specimens

LO 46.13

Although wet mounts are a useful tool for detecting microorganisms, microorganisms and their structures can be seen more clearly when you stain them with a dye or group of dyes. As with wet mounts and KOH mounts, the doctor can make a quick, tentative diagnosis with stained specimens. A stained specimen also enables the doctor to differentiate between types of infections, like bacterial and yeast infections, or between bacterial infections of one type and another. Stains also help doctors identify microorganisms that have grown on culture plates.

Preparation of Smears

The first step in staining a microbiologic specimen is to prepare a smear. To do so, simply apply a small amount of the specimen in a thin layer on a glass slide. Allow the sample to dry and

then briefly heat the slide to “fix” the sample to the slide so that it does not wash off during the staining process. The steps are described in detail in Procedure 46-4 at the end of this chapter.

Gram Stain

The Gram stain is the most frequently used stain for microscopic examination of bacteriologic specimens. This stain is a moderate-complexity test that you may assist with in the medical office if you have additional training. The steps for performing a Gram stain are outlined in Procedure 46-5 at the end of this chapter.

A Gram stain involves performing a series of staining and washing steps on the heat-fixed smear. First, apply a purple stain called crystal violet (also known as gentian violet) to the smear. After washing the slide in water, apply iodine. The iodine acts as a **mordant**, a substance that fixes a stain, keeping it from being washed away. Iodine helps bind the dye to the bacterial cell wall.

After washing the slide again in water, apply a decolorizing solution (alcohol or acetone-alcohol). As you learned earlier in the chapter, certain bacterial species retain the purple dye even after the decolorizer is added. These bacteria appear blue or violet and are Gram-positive. (positive because they retained the purple dye).

Other bacteria lose their purple color when the decolorizer is added. To allow the physician to visualize these bacteria, apply a red counterstain (safranin) to the smear. Bacteria that lose the purple color and pick up the red color of the safranin are Gram-negative. Figure 46-12 illustrates Gram-positive and Gram-negative bacteria. It is important that you follow each step in the Gram stain process carefully to reduce the likelihood of misidentifying the microorganisms.

On the basis of a bacterium’s staining characteristics and the shape and arrangement of cells, the physician can make a presumptive identification of an organism. For example, clusters of cocci that appear Gram-positive typically suggest an infection with staphylococci.

► Culturing Specimens in the Medical Office

LO 46.14

If your medical office is equipped with a laboratory and if you have had the necessary on-the-job training or additional courses, you may be required to culture certain specimens. It is, however, becoming more common for doctors’ offices to send specimens to outside laboratories because of Clinical Laboratory Improvement Amendments of 1988 (CLIA ’88) guidelines and the additional requirements concerning personnel and administrative work.

Culturing involves placing a sample of the specimen on or in a specialized culture medium, which contains nutrients that enable microorganisms such as bacteria and fungi to grow. The medium is placed in an incubator set at 37°C (body temperature), the optimal temperature for growth. As the microorganism multiplies, a **colony**—a distinct group of the organisms—can be seen on the culture medium’s surface. The microorganism is identified according to the colony

(a)

(b)

FIGURE 46-12 (a) Gram-positive organisms appear blue or violet after staining. (b) Gram-negative organisms appear red.
(a) CDC/P.B. Smith; (b) CDC

appearance, its staining characteristics, and certain biochemical reactions. A microorganism's biochemical reactions are determined by their growth on specific types of culture media.

Culture Media

Culture media come in liquid, semisolid, and solid forms. In the medical office, you will most likely work with a semisolid. The medium contains **agar**, a gelatin-like substance derived from seaweed, which gives the medium its consistency. This form of medium comes commercially prepared in culture plates—round, covered, glass or plastic dishes called *petri dishes*.

Handle petri dishes on the outside only, so that they do not become contaminated. You can avoid introducing contaminants by storing the petri dishes with the agar side up. Use the palm of your hand to pick up the agar-containing part of the dish when you are ready to inoculate it with a specimen.

Types of Media Many different types of semisolid media are commercially available. The type of medium used for culturing depends on the type of suspected organism and the site from which the specimen is obtained. Some types—called selective media—allow (select for) the growth of certain kinds of bacteria while inhibiting the growth of others. Selective

media are commonly used for specimens that normally contain bacteria, such as stool or vaginal samples. This is so that you can select for pathogenic organisms and not grow those that you expect to find.

Other types of media support the growth of most organisms and are referred to as nonselective media. The most common type of culture medium used in the laboratory is blood agar, a nonselective medium. Blood agar gets its red color from sheep's blood. Comparing the growth of a specimen on selective and nonselective media often provides important information about the microorganisms present.

You will typically use a blood agar plate when you culture a throat swab specimen. The organism that causes strep throat (*Streptococcus pyogenes*) can be identified when it grows on blood agar because it destroys the blood cells (hemolysis) in the agar, leaving a clear zone surrounding each colony.

Special Culture Units Small physicians' office laboratories often use commercial culture units with specific culturing purposes. Units for performing rapid urine culture, such as Uricult® (manufactured by Orion Diagnostica, Somerset, New Jersey), are typical. Uricult® consists of a small vial with a double-sided paddle attached to a screw-on top (Figure 46-13). Each side of the paddle contains a different type of medium on its surface. To culture a urine specimen, simply dip the media paddle into the clean-catch mid-stream urine specimen or catheterized specimen, coating both sides of the paddle. Then remove the paddle from the specimen, screw it into the vial, and place it upright in the incubator for 18 to 24 hours. If bacteria are present, they will grow on the surfaces of the media. Other units for culturing urine, throat specimens, vaginal specimens, and blood are also simple to use. These units usually enable you to obtain an estimate of the number of bacteria in the sample in addition to identifying the bacteria.

Inoculating a Culture Plate

Inoculating a culture plate involves transferring some or all of the specimen onto the plate. Before inoculating a plate, label it

FIGURE 46-13 The Uricult® is one type of urine culture device consists of a lid and attached, double-sided paddle that screws into a vial. Courtesy Orion Diagnostica

FIGURE 46-14 When inoculating a plate for qualitative analysis, roll and streak the culture swab or streak the inoculating loop of specimen material across one-third of the surface of the culture plate. Begin the next pass with a sterile loop.

on the bottom (agar side) rather than the lid because the lid can be lost or switched. Write close to the edge to avoid obscuring colony identification. Label the plate with the patient's name, doctor's name, source of the sample, date and time of inoculation, and your initials. You can apply a label or write the information with a grease pencil or permanent marker.

In the case of a specimen swab, inoculate the plate by streaking the swab across the plate. Bacterial colonies can be identified by their appearance. This determination of the type of pathogen is referred to as a qualitative analysis of the specimen.

To perform a qualitative analysis of a specimen such as urine, introduce only a small portion of the specimen onto the plate. A calibrated inoculating loop is used for this purpose. A loop is a small circle of wire or plastic attached to a long handle. When this loop is dipped into the specimen, a small, specific amount of liquid can be transferred to the plate. Different sizes of calibrated loops deliver different volumes of fluid. For example, calibrated loops may allow you to pick up either 0.01 or 0.001 milliliter of liquid.

In addition, you may need to perform a separate determination—called a quantitative analysis—of the number of bacteria present in specimens such as urine. A quantitative analysis is important with such a specimen because a few bacteria may contaminate a urine sample during collection. A true infection is confirmed by the presence of a specified number of bacteria; any number beneath this level is typically considered contamination.

Inoculating for Qualitative Analysis To inoculate an agar plate for qualitative analysis, perform the first pass with a culture swab (as with a throat culture) or an inoculating loop (as with a urine culture). If you use a culture swab, roll and streak it back and forth across an area, covering roughly one-third of the culture plate to deposit the microorganisms. When using an inoculating loop, spread the material by streaking the loop across one-third of the plate in the same back-and-forth pattern. Figure 46-14 shows the correct pattern for inoculating a plate.

Because there may be several microorganisms in the specimen, you need to streak the inoculated (firstpass) area with a sterile loop to separate out individual colonies that can be

identified on the remaining areas of the culture plate. Unless you use a sterile disposable loop, first sterilize the loop by heating it in a bacterial loop incinerator until it glows red. Allow the loop to cool and then pass it once across the inoculated area of the plate to pick up a small number of microorganisms. Then streak it in a back-and-forth pattern over the second one-third of the plate. Next, sterilize the loop again, pass it once across the second inoculated area of the plate, and then streak it back and forth over the last one-third of the plate. Each successive pass reduces the microorganism concentration. This procedure allows isolated colonies, or colony-forming units, to be observed in the area of the last pass of the loop, as Figure 46-15 shows.

For throat cultures, the physician may simply want you to screen the sample for the presence of streptococcal organisms. You may not need to use a loop to spread the microorganisms; the swab will be sufficient, as described in Procedure 46-1, at the end of this chapter, when preparing the specimen for screening.

FIGURE 46-15 You can see individual colony-forming units in the last third of an inoculated culture plate.
CDC

FIGURE 46-16 When inoculating a plate for quantitative analysis, (a) streak the loop down the center of the plate. Next, (b) streak the loop at right angles to the first inoculation. Then, (c) turn the plate 90° and streak the entire surface once more.

Inoculating for Quantitative Analysis To perform a quantitative analysis of a urine specimen, use a calibrated loop to withdraw a portion of urine from the sample. Be sure the urine specimen is well mixed before taking the sample, as the microorganisms may settle to the bottom of the specimen cup. Sterilize, cool, and dip the calibrated loop into the sample. Transfer the entire volume to the surface of an agar plate by making a single streak down the center of the plate. Next, spread the specimen evenly across the plate at a right angle to the initial streak, using the same loop (without sterilizing it). Turn the plate and spread the material again, at a right angle to the last streak, over the entire surface. Figure 46-16 illustrates this technique.

After the microorganisms are allowed to grow for 24 hours, estimate the number of microorganisms by counting the number of colonies that appear on the surface of the plate. For example, if you use a 0.001 milliliter calibrated loop to streak the plate and 50 colonies grow, multiply the 50 colonies by 1,000 to obtain the number of colonies per milliliter. In this case, you would estimate there are 50,000 colony-forming units per milliliter of urine. You must be especially careful that your counts and calculations are correct so that the doctor has accurate information on which to base a diagnosis.

Incubating Culture Plates

After inoculating a plate, place it in an incubator set at 35°C (95°F) to 37°C (98.6°F) (human body temperature) to allow the bacteria to grow. Plates are always incubated with the agar side up, so that any moisture that collects in the plate will fall on the inside of the lid and not on the microbes growing on the surface of the agar. How long plates are allowed to incubate varies with the type of culture. Most bacteria grow sufficiently within 24 hours, but some require 48 hours. Fungi typically take longer to grow than bacteria and may grow at a slightly lower temperature (95°F to 96.8°F).

Interpreting Cultures

After incubation, cultures are assessed for growth and are interpreted. This process requires considerable skill and practice because pathogens must often be differentiated from

resident normal flora. This step may be performed by the physician, a microbiologist, or a technician who has been properly trained to do so through on-the-job training or additional coursework.

The process of interpreting a culture typically involves several determinations. The characteristics of the colonies growing on the agar are noted, along with their relative numbers. In addition, any changes in the media surrounding the colonies are noted because changes may reflect certain characteristics of the microorganism.

The physician decides at this point whether additional procedures are required. In the case of a throat culture, the presence of colonies of a characteristic shape, size, and color, surrounded by areas of hemolysis, suggests strep throat, as shown in Figure 46-17. A Gram stain and determination of bacterial shape may be all that is necessary for a confirmed diagnosis. Many cultures, however, require additional biochemical and, in some cases, serologic tests for definitive pathogen identification. Since this is an advanced skill, either the physician or an outside microbiology laboratory will make the final interpretation of the cultured microorganism.

FIGURE 46-17 A positive strep throat culture contains distinctive colonies surrounded by areas of hemolysis.

PROCEDURE 46-1 Obtaining a Throat Culture Specimen **WORK // DOC**

Procedure Goal: To isolate a pathogenic microorganism from the throat or to rule out strep throat

OSHA Guidelines:

Materials: Patient chart/progress note, tongue depressor, sterile collection system or sterile swab plus blood agar culture plate

Method:

1. Identify the patient, introduce yourself, and explain the procedure.
2. Assemble the necessary supplies; label the culture plate if used.
3. Wash your hands and don examination gloves, goggles, and a mask or face shield.

RATIONALE: *The patient may cough while you swab the throat.*

4. Have the patient assume a sitting position. (Having a small child lie down rather than sit may make the process easier. If the child refuses to open the mouth, gently squeeze the nostrils shut. The child will eventually open the mouth to breathe. Enlist the help of the parent to restrain the child's hands if necessary.)
5. Open the collection system or sterile swab package by peeling the wrapper halfway down; remove the swab with your dominant hand.
6. Ask the patient to tilt back her head and open her mouth as wide as possible.
7. With your other hand, depress the patient's tongue with the tongue depressor.
8. Ask the patient to say "Ah."
9. Insert the swab and quickly swab the back of the throat in the area of the tonsils, twirling the swab over representative areas on both sides of the throat. Avoid touching the uvula (the soft tissue hanging from the roof of the mouth), the cheeks, or the tongue.

RATIONALE: *Touching these areas will contaminate the specimen.*

10. Remove the swab and then the tongue depressor from the patient's mouth.
11. Discard the tongue depressor in a biohazardous waste container.

To Transport the Specimen to a Reference Laboratory

12. Immediately insert the swab back into the plastic sleeve, being careful not to touch the outside of the sleeve with the swab.
13. Crush the vial of transport medium to moisten the tip of the swab.

FIGURE Procedure 46-1 Step 9 When obtaining a throat culture specimen, swab the back of the throat in the area of the tonsils on each side, taking care to avoid touching the uvula.

RATIONALE: *To keep the microorganisms alive during transport.*

FIGURE Procedure 46-1 Step 13 The transport medium released from the crushed capsule keeps microorganisms alive while in transit to the laboratory for culturing.

14. Label the collection system and arrange for transport to the laboratory.

To Prepare the Specimen for Evaluation in the Physician's Office Laboratory

12. Immediately inoculate the culture plate with the swab, using a back-and-forth motion.
13. Discard the swab in a biohazardous waste container.
14. Place the culture plate in the incubator.

When Finished with All Specimens

15. Remove the gloves and wash your hands.
16. Document the procedure in the patient's chart.

PROCEDURE 46-2 Performing a Quick Strep A Test on a Throat Specimen

WORK // DOC

Procedure Goal: To determine the presence of strep A antigen in a throat specimen

OSHA Guidelines:

Materials: Patient chart/progress note, strep A testing kit, throat swab specimen, and a timer or watch

Method:

1. Review the laboratory requisition form and gather the supplies.
2. Confirm the patient's identity, introduce yourself, and explain the procedure.
3. Wash your hands and don gloves, goggles, and a mask or face shield.
4. Open the strep A testing kit and check the expiration date on the kit.

5. Obtain a throat specimen with a sterile swab, being careful not to touch the tongue, teeth, or cheeks.
RATIONALE: *Swabbing only the throat reduces the likelihood of getting a false positive test result.*
6. Complete the quality control tests provided with the testing kit.
RATIONALE: *To ensure the test is working correctly*
7. Put the required amount of the first reagent in the test tube or testing device provided in the kit.
8. Place the swab into the test tube or testing device. Following the manufacturer's instructions, swirl the swab and press it against the sides of the tube or device.
9. Add the second reagent as directed.
10. Read the results at the required time.
11. Dispose of testing supplies in the appropriate waste container according to OSHA requirements.
12. Remove your gloves and wash your hands.
13. Document the results in the patient's chart.

PROCEDURE 46-3 Preparing Microbiologic Specimens for Transport to an Outside Laboratory

WORK // DOC

Procedure Goal: To properly prepare a microbiologic specimen for transport to an outside laboratory

OSHA Guidelines:

Materials:

Specimen-collection device, requisition form, secondary container or a zipper-type plastic bag

Method:

1. Wash your hands and don examination gloves (and goggles and a mask or face shield if you are collecting a microbiologic throat culture specimen).
2. Obtain the microbiologic culture specimen.
 - a. Use the collection system specified by the outside laboratory for the test requested.
 - b. Label the microbiologic specimen-collection device at the time of collection.
 - c. Collect the microbiologic specimen according to the guidelines provided by the laboratory and office procedure.

RATIONALE: *To ensure the specimen is correctly collected and handled.*

3. Remove the gloves and wash your hands.
4. Complete the test requisition form.
5. Place the microbiologic specimen container in a secondary container or zipper-type plastic bag.
RATIONALE: *To prevent contaminating anyone who handles the specimen during transport.*
6. Attach the test requisition form to the outside of the secondary container or bag, per laboratory policy.
7. Log the microbiologic specimen in the list of outgoing specimens.
RATIONALE: *So that you can follow up on lab tests sent to outside laboratories.*
8. Store the microbiologic specimen according to guidelines provided by the laboratory for that type of specimen (for example, refrigerated, frozen, or 37°C).
9. Call the laboratory for pickup of the microbiologic specimen, or hold it until the next scheduled pickup.
10. At the time of pickup, ensure that the carrier takes all microbiologic specimens that are logged and scheduled to be picked up.
11. If you are ever unsure about collection or transportation details, call the laboratory.

PROCEDURE 46-4 Preparing a Microbiologic Specimen Smear

Procedure Goal: To prepare a smear of a microbiologic specimen for staining

OSHA Guidelines:

Materials: Glass slide with frosted end, pencil, specimen swab, Bunsen burner, and forceps

Method:

1. Wash your hands and don exam gloves.
2. Assemble all the necessary items.
3. Use a pencil to label the frosted end of the slide with the patient's name.
4. Roll the specimen swab evenly over the smooth part of the slide, making sure all areas of the swab touch the slide.

RATIONALE: To make sure a representative specimen is transferred to the slide.

5. Discard the swab in a biohazardous waste container. (Retain the microbiologic specimen for culture as necessary or according to office policy.)
6. Allow the smear to air-dry. Do not wave the slide to dry it.

RATIONALE: Waving the slide may spread pathogens or contaminate the slide.

FIGURE Procedure 46-4 Step 4 Rolling the swab ensures that representative microorganisms collected on it are deposited on the slide.

© Cliff Moore

7. Heat-fix the slide by holding the frosted end with forceps and passing the clear part of the slide, with the smear side up, through the flame of a Bunsen burner three or four times. (Your office may use an alternate procedure for fixing the slide, such as flooding the smear with alcohol, allowing it to sit for a few minutes, and either pouring off the remaining liquid or allowing the smear to air-dry. Chlamydia slides come with their own fixative.)
RATIONALE: The specimen must be fixed to the slide to prevent washing the microorganism off during staining or handling.
8. Allow the slide to cool before the smear is stained.
9. Return the materials to their proper location.
10. Remove the gloves and wash your hands.

PROCEDURE 46-5 Performing a Gram Stain

Procedure Goal: To make bacteria present in a specimen smear visible for microscopic identification

OSHA Guidelines:

Materials: Heat-fixed smear, slide staining rack and tray, crystal violet dye, iodine solution, alcohol or acetone-alcohol decolorizer, safranin dye, wash bottle filled with water, forceps, and blotting paper or paper towels (optional)

Method:

1. Assemble all the necessary supplies.

2. Wash your hands and don examination gloves.
3. Place the heat-fixed smear on a level staining rack and tray, smear side up.
4. Completely cover the specimen area of the slide with the crystal violet stain.

FIGURE Procedure 46-5 Step 4 Apply crystal violet. Wait 1 minute.

(Many commercially available Gram stain solutions have flip-up bottle caps that allow you to dispense stain by the drop. If the stain bottle you are using does not have an attached dropper cap, use an eyedropper.)

5. Allow the stain to sit for 1 minute; rinse the slide thoroughly with water from the wash bottle.

FIGURE Procedure 46-5 Step 5 Wash the slide with water.

RATIONALE: *Rinsing the slide after 1 minute stops the staining process and prevents overstaining.*

6. Use the forceps to hold the slide at the frosted end, tilting the slide to remove excess water.
7. Place the slide flat on the rack again and completely cover the specimen area with iodine solution.

FIGURE Procedure 46-5 Step 7 Apply iodine solution. Wait 1 minute.

8. Allow the iodine to remain for 1 minute; rinse the slide thoroughly with water.

RATIONALE: *The iodine helps increase cell staining.*

FIGURE Procedure 46-5 Step 8 Rinse the slide with water.

9. Use the forceps or a gloved hand to hold and tilt the slide to remove excess water.
10. While still tilting the slide, apply the alcohol or decolorizer drop by drop until no more purple color washes off. (This step usually takes 10 seconds to 30 seconds.)

RATIONALE: *The decolorizing step is essential for differentiation between Gram-positive and Gram-negative bacteria.*

FIGURE Procedure 46-5 Step 10 Apply decolorizing solution.

11. Rinse the slide thoroughly with water; use the forceps to hold and tip the slide to remove excess water.

FIGURE Procedure 46-5 Step 11 Wash the slide with water.

12. Completely cover the specimen with safranin dye.

FIGURE Procedure 46-5 Step 12 Apply safranin dye to the slide. Wait 1 minute.

13. Allow the safranin to remain for 1 minute; rinse the slide thoroughly with water.

RATIONALE: To counterstain the specimen so that Gram-negative organisms can be visualized.

FIGURE Procedure 46-5 Step 13 Rinse the slide with water.

14. Use the forceps to hold the stained smear by the frosted end and carefully wipe the back of the slide to remove excess stain.
15. Place the smear in a vertical position and allow it to air-dry or blot it lightly between blotting paper to hasten drying. Take care not to rub the slide, or the specimen may be damaged.

FIGURE Procedure 46-5 Step 15 Blot and allow the slide to air-dry.

16. Sanitize and disinfect the work area.
17. Remove the gloves and wash your hands.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
46.1 Explain the medical assistant's role in microbiology.	As an office medical assistant, you may assist the physician with several microbiologic procedures that aid in diagnosing and treating infectious diseases, including obtaining specimens or assisting the physician in doing so; preparing specimens for direct examination by the physician; and preparing specimens for transportation to a microbiology laboratory for identification.
46.2 Summarize how microorganisms cause disease.	Microorganisms can cause disease by using up nutrients or other materials needed by the cells and tissues they invade, damaging body cells, and producing toxins.
46.3 Describe how microorganisms are classified and named.	Microorganisms are classified on the basis of their structure. Specific microorganisms are named in a standard way, using the genus (a category of biologic classification between the family and the species) to which the microorganism belongs and the particular species of the organism.
46.4 Discuss the role of viruses in human disease.	Viruses are among the smallest known infectious agents causing common diseases, including the common cold, influenza, chickenpox, croup, hepatitis, and warts.
46.5 Discuss the role of bacteria in human disease.	Bacteria are single-celled, prokaryotic organisms that reproduce very quickly and cause diseases such as pneumonia, tuberculosis, meningitis, boils, urinary tract infections, Lyme disease, cholera, and tetanus.
46.6 Discuss the role of protozoans in human disease.	Protozoans are single-celled, eukaryotic organisms found in soil and water. They can cause malaria, amebic dysentery, and trichomoniasis vaginitis.
46.7 Discuss the role of fungi in human disease.	Fungi are eukaryotic organisms, including molds and yeasts. Diseases caused by fungi include athlete's foot, thrush, ringworm, and vaginal yeast infections.

LEARNING OUTCOMES	KEY POINTS
46.8 Discuss the role of multicellular parasites in human disease.	Multicellular parasites include roundworms, tapeworms, flatworms, ticks, lice, and mites.
46.9 Describe the process involved in diagnosing an infection.	The steps involved in diagnosing an infection are to examine the patient, obtain one or more specimens, examine the specimen directly by either wet mount or smear, culture the specimen, and determine the culture's antibiotic sensitivity.
46.10 Identify general guidelines for obtaining specimens.	The general guidelines for obtaining specimens are to obtain the specimen with great care to avoid causing the patient harm, discomfort, or undue embarrassment; collect the material from a site; obtain the specimen at the proper time; use appropriate collection devices; obtain a sufficient quantity of the specimen; and obtain the specimen before antimicrobial therapy begins.
46.11 Carry out the procedure for transporting specimens to outside laboratories.	When transporting specimens to outside laboratories, the medical assistant should follow proper collection techniques using specific containers provided by the laboratory, maintain the samples in a state as close to their original as possible, and protect anyone who handles a specimen container from exposure to potentially infectious material.
46.12 Compare two techniques used in the direct examination of culture specimens.	Direct examination of culture specimens is accomplished in two ways: wet mounts and KOH mounts.
46.13 Carry out the procedure for preparing and examining stained specimens.	To prepare a stained specimen, the medical assistant must first prepare a smear, fix the sample to the slide so that it does not wash off during the staining process, and follow a specific staining procedure. The sample is then observed under a microscope for certain characteristics.
46.14 Carry out the procedure for culturing specimens in the medical office.	To culture a specimen, the medical assistant should place a sample of the specimen on or in a specialized culture medium and allow it to grow in an incubator for 24 to 48 hours.

CASE STUDY CRITICAL THINKING

© Red Chopsticks/Getty Images RF

Recall Cindy Chen from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding her case.

1. Why are Cindy's helper T cells being tested?
2. As Cindy's HIV infection progresses, what symptoms might she exhibit?

3. What special precautions should you take when drawing Cindy's blood?
4. Why do you think Dr. Whalen asked you to send the throat culture to the reference lab instead of doing a rapid strep test in the POL?

EXAM PREPARATION QUESTIONS

- (LO 46.1) Microorganisms normally found on the skin and other body tissues are known as
 - Tissue pathogens
 - Viruses
 - Resident normal flora
 - Colonies
 - Infections
- (LO 46.3) Which of the following is an example of a subcellular microorganism?
 - Bacterium
 - Virus
 - Fungus
 - Helminth
 - Multicellular organism
- (LO 46.9) A specimen that is spread thinly and evenly across a slide is a
 - Smear
 - Wet prep
 - Culture
 - Medium
 - Streak
- (LO 46.12) A KOH mount is used to detect which of the following?
 - Gonococci
 - Fungi
 - Viruses
 - Pinworms
 - HIV
- (LO 46.10) Which of the following is an appropriate guideline for collecting specimens?
 - The specimen label includes the patient's name and number, source of specimen, date and time, doctor's name, and your initials
 - The best location to obtain a throat culture to diagnose strep throat is from the sides of the throat
 - When a patient is collecting a specimen on her own, you should trust that she knows how to do it without an explanation
 - When a patient is taking an antibiotic, you should never obtain a specimen
 - Allow the patient to use a container from home to collect a sputum specimen
- (LO 46.2) Organisms capable of causing disease are known as
 - Commensals
 - Flora
 - Pathogens
 - Facultative
 - Aerobes
- (LO 46.4) Infectious mononucleosis is caused by which of the following?
 - Adenovirus
 - Parvovirus
 - Norovirus
 - Epstein-Barr virus
 - Rotavirus
- (LO 46.7) Athlete's foot, thrush, and ringworm are all caused by types of
 - Prions
 - Parasites
 - Bacteria
 - Viruses
 - Fungi
- (LO 46.13) A substance that fixes a stain, keeping it from being washed away, is a
 - Mordant
 - Substrate
 - Wash
 - Dye
 - Counterstain
- (LO 46.8) An organism that lives on or in another organism and uses that other organism for its own nourishment is a(n)
 - Obligate
 - Eukaryote
 - Resident
 - Parasite
 - Prokaryote

SOFT SKILLS SUCCESS

Recall Cindy Chen from the case study at the beginning of the chapter. After drawing Cindy's blood, you leave her lab requisition on the counter at the front of the lab while you escort her to the front office. When you return, Charlie Goodpasture is waiting to have his blood drawn for routine lab work. You notice he is glancing at the lab requisition you left on the counter. He asks you if that was Cindy Chen he saw. He also tells you that he knew Cindy from phlebotomy school

and she has lost a lot of weight. Charlie asks if Cindy is sick. How should you handle this situation? What should you have done differently?

Collecting, Processing, and Testing Urine and Stool Specimens

47

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Ken Washington	12/1/19XX	Sulfa
PATIENT INFORMATION	Attending	MRN	Other Information
	Paul F. Buckwalter, MD	891-12-743	Vital Signs: BP 142/88, T 99.2, P 76, R 16

Ken Washington, a 61-year-old male patient, arrived today for a follow-up visit from a recent hospitalization for a stroke. Up until this hospitalization, he has had no major health issues. He now has weakness in his left arm and his speech is difficult to understand. His wife tells you that

© McGraw-Hill Education

she has noticed some blood in the toilet after he urinates. She also tells you that he has had some pain when he urinates and often only urinates a small amount. Dr. Buckwalter would like for you to obtain a urine sample for a reagent test and have Ken collect a 24-hour urine sample for analysis.

Keep Ken in mind as you study this chapter.

There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

 **ACTIVSim**

LEARNING OUTCOMES

After completing Chapter 47, you will be able to:

- 47.1** Discuss the role of the medical assistant in collecting, processing, and testing urine and stool samples.
- 47.2** Carry out procedures for collecting urine specimens according to guidelines.
- 47.3** Describe the process of urinalysis and its purpose.
- 47.4** Carry out the proper procedure for collecting and processing a stool sample for fecal occult blood testing.

KEY TERMS

anuria	O&P specimen
cast	oliguria
catheterization	proteinuria
clean-catch mid-stream urine specimen	refractometer
crystal	supernatant
fecal occult blood test (FOBT)	24-hour urine specimen
first morning urine specimen	urinalysis
glycosuria	urinary pH
hematuria	urine culture
	urine specific gravity
	urobilinogen

- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.11** Obtain specimens and perform:
 - (c) CLIA waived urinalysis
- I.A.3** Show awareness of a patient's concerns related to the procedure being performed
- II.P.2** Differentiate between normal and abnormal test results
 - II.A.1** Reassure a patient of the accuracy of the test results
- III.P.2** Select appropriate barrier/personal protective equipment (PPE)
 - III.A.1** Recognize the implications for failure to comply with Centers for Disease Control (CDC) regulations in healthcare settings
- X.P.3** Document patient care accurately in the medical record

3. Medical Terminology

- d. Define and use medical abbreviations when appropriate and acceptable

4. Medical Law and Ethics

- f. Comply with federal, state, and local health laws and regulations as they relate to healthcare settings

9. Clinical Procedures

- a. Practice standard precautions and perform disinfection/sterilization techniques
- e. Perform specialty procedures including but not limited to minor surgery, cardiac, respiratory, OB-GYN, neurological, gastroenterology
 - j. Make adaptations with patients with special needs

10. Medical Laboratory Procedures

- a. Practice quality control
- b. Perform selected CLIA-waived tests that assist with diagnosis and treatment
 - (1) Urinalysis
 - (6) Kit testing
 - a. Pregnancy
 - c. Dip sticks
- c. Dispose of biohazardous materials
- e. Instruct patients in the collection of a clean-catch mid-stream urine specimen
 - (1) Clean-catch mid-stream urine specimen (CCMS, 24-hour, etc.)
 - (2) Collection of fecal specimen

► Introduction

Proper collection and testing of urine and stool (fecal) samples is a crucial step in the diagnostic process. The routine analysis of a urine specimen is a simple, noninvasive diagnostic test that provides a healthcare provider with a window to a patient's health. Many significant conditions may be noted as a result of the physical, chemical, and microscopic examinations of a patient's specimen. In this chapter, you will learn about various types of urine specimens and how to properly instruct or assist patients with their collection. Additionally, you will learn how to correctly process a specimen, including a random specimen and a chain-of-custody drug screen. You will learn to identify normal and abnormal constituents of urine samples and what may cause these abnormal elements to be present in a specimen. You also will learn about stool samples, which are collected for a variety of reasons, including detecting bacterial infections, detecting parasites, and screening for cancer. Teaching patients proper techniques for collecting stool samples is key to getting accurate test results.

► The Role of the Medical Assistant LO 47.1

In your role as a medical assistant, you will help collect, process, and test urine and stool specimens. To perform your duties, you need to know about the anatomy and physiology of the kidneys, how urine is formed, and what its normal contents are. You also will need to understand the anatomy and physiology of the digestive system. This information will help you collect various specimen types, process them, and perform tests on them. Be sure to review the anatomy and physiology of the urinary system and the digestive system in chapters *The Urinary System* and *The Digestive System*. Also, see Table 47-1 for a list of abbreviations commonly used in urine analysis and stool testing. Dealing with a variety of patient groups who require special care, including elderly patients and pediatric patients, also will be an important part of your job.

When obtaining and processing urine and stool specimens, you will deal with potentially infectious body waste. For this reason, you must take precautions to protect yourself, the

TABLE 47-1 Abbreviations Common to Urine Analysis and Stool Testing

BIL; bili; BR	bilirubin	RBCs	red blood cells
Ca	calcium	SPG; sp gr; sp.gr.	specific gravity
CC	clean-catch (urine)	U/A	urinalysis
CCMS	clean-catch, mid-stream (urine)	UBG	urobilinogen
CL VOID	clean voided specimen (urine)	U/C	urine culture
CrCl	creatinine clearance	UC	urinary catheter
CSU	catheter specimen (urine)	UC&S	urine culture and sensitivity
Cys	cysteine	UcaV	urinary calcium volume
CYS	cystoscopy	UCRE	urine creatinine
EMU	early morning urine(s)	UFC	urinary free cortisol
FOBT	Fecal occult blood test	UK	urine potassium
HCG; hcg; hCG	human chorionic gonadotropin	UNa	urinary sodium
IVP	intravenous pyelogram	Uosm	urine osmolality
K	potassium	UTI	urinary tract infection
Na	sodium	UUN	urinary urea nitrogen
O&P	Ova and parasites	UV	urinary volume
pH	hydrogen ion concentration	Vol	volume
PKD	polycystic kidney disease	WBCs	white blood cells
PKU	phenylketonuria		

patient, and others in the environment from transmitting disease-causing microorganisms. Most medical offices use standard precautions when dealing with urine. (See the *Infection Control Fundamentals* chapter for detailed information on these precautions.) During all procedures, you must be sure to wear adequate personal protective equipment (PPE); handle and dispose of specimens properly; dispose of used supplies and equipment properly; and sanitize, disinfect, and/or sterilize all reusable equipment according to facility policy.

► Obtaining Urine Specimens LO 47.2

It is essential to collect, store, and preserve urine specimens in ways that do not alter their physical, chemical, or microscopic properties. You must follow guidelines each time you obtain specimens and instruct patients in the proper guidelines to follow.

General Collection Guidelines

When you collect urine specimens from patients, follow these guidelines:

- Follow the procedure specified for the urine test that will be performed.
- Use the type of specimen container indicated by the laboratory. If a patient must bring in a specimen, be sure the container is provided by the licensed practitioner's office or that it's appropriate for the testing protocol. If you provide the patient with a container that contains a preservative, make sure the appropriate warning labels are attached. You also should warn patients that the additive may contain acid and they should take care not to spill the acid on themselves.

- Label the specimen container before giving it to the patient or on receipt of a container the patient provides. Include the patient's name, the licensed practitioner's name, the date and time of collection, and your initials. Label the side of the specimen container, not the lid, because lids may be lost or switched.
- If the patient is having an invasive test, such as catheterization, always explain the procedure to the patient completely, using simple, clear language.
- If you are assisting in the collection process, wash your hands before and after the procedure and wear gloves during the procedure.
- If the urine specimen needs to be transferred to another container or if it is to be sent to a reference lab for testing, use a urine transfer straw or provide the patient with a container that has a transfer straw integrated into the collection cup. Label the container.
- Complete all necessary paperwork, recording the collection in the patient's chart and making sure you use the correct laboratory request slip for the ordered test.

In many instances, patients need to collect a urine specimen at home. It is your responsibility to give patients instructions for obtaining the specific type of specimen. In addition, provide them with the following general instructions:

- Urinate into the container indicated by the laboratory. In most instances, urinate into a wide-mouthed, throw-away, spouted specimen container as instructed. Do not add anything to the container except the urine.
- If the collection container contains liquid or powdered preservative, do not pour it out.

- If any of the preservative spills on you, wash the area immediately and contact the licensed practitioner's office.
- Always refrigerate the labeled collection container or keep it in a cooler or pail filled with ice.
- Be sure to keep the lid on the container.

Specimen Types

Many different tests are performed on urine. You may need to obtain different types of specimens for different tests, such as quantitative analysis or qualitative analysis. A quantitative analysis is a test that measures the amount of a specific substance in the urine. A qualitative analysis simply indicates the presence (or absence) of a substance in urine. Specimens vary in two ways: in the method used to collect them and in the time frame in which they are collected.

Quality assurance is essential in the licensed practitioner's office laboratory. As discussed in the *Orientation to the Lab* chapter, control samples must be used every time you test patient specimens. These are the types of urine specimens:

- Random
- First morning
- Clean-catch mid-stream
- Timed
- 24-hour

Random Urine Specimen The random urine specimen is the most common type of sample. It is a single urine specimen taken at any time of the day and collected in a clean, dry container.

If a random urine specimen collection is to be done at the licensed practitioner's office, supply the patient with a urine specimen container. Show the patient to the bathroom and ask the patient to void a few ounces of urine into the specimen cup and to leave the cup on the sink. Retrieve the specimen when the patient leaves the bathroom, and attach a properly completed label and requisition slip. Transport the specimen to the laboratory immediately. Urine specimens should be processed within 1 hour of collection. If this is not possible, refrigerate the specimen. Before processing refrigerated specimens, however, allow them to come to room temperature before processing them. If specimens will be shipped to an outside laboratory, chemical preservatives are added, or the specimens are transferred to a suitable container containing preservatives.

If patients are to collect a random urine specimen at home, have them use the container indicated by the laboratory. Either provide patients with a urine specimen container or instruct them to use a clean, wide-mouthed glass jar with a tight-fitting lid. Explain that a household dishwasher provides hot enough water to disinfect a jar adequately. Tell patients to refrigerate specimens until they bring them to the licensed practitioner's office and to keep them cool during transport.

First Morning Urine Specimen The **first morning urine specimen** is collected after a night's sleep. This type of specimen contains greater concentrations of substances that collect over time than do specimens taken during the day.

A urine specimen container or clean, dry jar is used to collect the urine as per the laboratory's request.

Clean-Catch Mid-Stream Urine Specimen The **clean-catch mid-stream urine specimen**, sometimes referred to as mid-void, may be collected and submitted for culturing to identify the number and types of pathogens present. A clean-catch mid-stream urine specimen may be collected at random or first thing in the morning. The presence of clinical symptoms or unexplained bacteria in a urinalysis specimen is an indication for urine culture.

The clean-catch mid-stream specimen method is not like other urine tests in which urine is simply voided into a specimen container. Instead, the clean-catch mid-stream method requires special cleansing of the external genitalia to avoid contamination by organisms residing near the urethral meatus (the external opening of the urethra). Voiding a small amount of urine into the toilet prior to collecting the mid-stream specimen flushes the normal flora out of the distal urethra to prevent possible contamination of the specimen. Procedure 47-1, at the end of this chapter, describes how to collect a clean-catch mid-stream urine specimen and how to instruct patients to perform this technique.

Timed Urine Specimen A licensed practitioner may order a timed urine specimen to measure a patient's urinary output or to analyze substances. First, determine whether the required time period means that the patient must collect the specimen at home. If so, provide the patient with the proper collection container; written instructions on the process, including specimen preservation; and the following oral instructions:

- Discard the first specimen.
- Then collect *all* urine for the specified time (2 to 24 hours).
- Be sure the urine does not mix with stool or toilet paper.
- Keep the sample refrigerated until returning it to the licensed practitioner's office or laboratory.

24-Hour Urine Specimen A **24-hour urine specimen** is collected over a 24-hour period and is used to complete a quantitative and qualitative analysis of one or more substances, such as sodium, chloride, and calcium. You need to instruct the patient in the proper collection process. If an outside laboratory will be testing the specimen, you will receive protocols for collection, preservation, and transport. Procedure 47-2, at the end of this chapter, outlines the steps in collecting a 24-hour urine specimen.

Catheterization

A urinary catheter is a sterile plastic tube inserted into the kidney, ureter, or bladder to provide urinary drainage. **Catheterization** is the procedure during which the

catheter is inserted, and it is performed for various reasons, including to

- Relieve urinary retention.
- Obtain a sterile urine specimen from a patient.
- Measure the amount of residual urine in the bladder to determine how much urine remains after normal voiding (patient voids and is then catheterized; more than 50 milliliters is considered abnormal).
- Obtain a urine specimen if the patient cannot void naturally.
- Instill chemotherapy as a treatment for bladder cancer.
- Empty the bladder before and during surgery and before some diagnostic exams.

The two primary types of urinary catheters are

- Drainage catheters, which are used to withdraw fluids. Drainage catheters include an indwelling urethral (Foley) catheter placed in the bladder; a retention catheter in the renal pelvis; a ureteral catheter; a catheter for drainage through a wound that leads to the bladder (cystostomy tube); and a straight catheter to collect specimens or instill medications.
- Splinting catheters, which are inserted after plastic repair of the ureter and must remain in place for at least a week after surgery.

Catheterization is not routinely recommended because it can introduce infection. Some states do not permit medical assistants to perform catheterization, and in most healthcare institutions, only a physician or nurse can insert or withdraw a catheter. Check the protocol in your state. If you are not permitted to perform the procedure, you may be asked to assemble the necessary supplies and to assist the licensed practitioner during the procedure.

Catheterization performed in a licensed practitioner's office is usually done for diagnostic purposes using a specially prepared catheterization kit. This kit contains all necessary

instruments and supplies, including a sterile instrument pack that is used to create a sterile field for the procedure.

If a patient is incontinent, the licensed practitioner may use a bladder-drainage catheter to help drain the bladder and keep the patient dry. Another type of drainage catheter, the ureteral, is inserted into the ureter to help drain urine.

The indwelling urethral (Foley) catheter is designed to stay in place within the bladder (Figure 47-1). It consists of two tubes, one inside the other. The outside tube is connected to a balloon, which is filled with water or air to keep the catheter from slipping out of the bladder. Urine travels through the bladder and drains from the inside tube into a soft plastic container. The licensed practitioner may order a leg bag to attach to the patient's thigh. The bag is anchored to the leg by two bands placed around the thigh. Make sure the bag is positioned so that there is no tension on the catheter tube. To prevent back-flow into the patient's bladder, the container must always be lower than the bladder.

Special Considerations

When you obtain a urine specimen from a patient or take a history of a patient who may have a urinary problem, you need to consider the patient's sex, condition, and age. Some patients require special care during collection procedures.

Special Considerations in Male and Female Patients

Depending on the test, you may need to alter guidelines for collecting urine specimens from a male or female patient. Procedure 47-1, at the end of this chapter, describes how to assist in collecting a clean-catch urine specimen from a female patient and from a male patient. In addition, when you take a medical history on a male or female patient, you will need to ask gender-specific questions as part of your assessment. For example, if a female patient leaks urine when laughing or coughing, she may have bladder dysfunction, which would affect the collection of a 24-hour urine specimen.

FIGURE 47-1 A Foley catheter stays in place within the bladder and has a collection container, which is emptied periodically.

Special Considerations in Pregnant Patients

Pregnant women normally have increased urinary frequency. They also may be prone to urinary tract infections. When a woman is pregnant, urine testing is done to screen for pregnancy-related issues. A pregnant woman’s urine is checked for glucose. If this test shows elevated glucose (sugar) in the urine, it may indicate the possibility of gestational diabetes. When the urine tests positive for glucose, additional testing is performed. The woman’s urine is also checked for abnormal levels of protein. Excess protein in her urine may indicate renal problems or preeclampsia, a condition brought on by pregnancy in which the blood pressure rises and other organs, such as the kidneys, may be damaged.

Ask a pregnant patient whether she has any pain during urination or in the kidney area. A positive response may indicate a urinary tract infection or kidney stones. Also ask about urine leakage and whether she has previously been pregnant. Leakage may occur in a woman who has had multiple births because the pressure of the fetus on the bladder or the delivery of the baby may have weakened the patient’s bladder control. Additionally, ask whether any of the babies were delivered by forceps, which can injure urinary and genital structures.

Establishing Chain of Custody

Occasionally, you may need to obtain urine specimens for drug and alcohol analysis. These are considered legal specimens because they may be used in a court of law and they must be handled carefully. The specimen must be placed in a specimen transfer bag that permanently seals the specimen bag until it is cut open for analysis. The seal ensures that there

has been no tampering with the bag’s contents prior to reaching the lab for testing. A chain of custody must be established to document the handling of this specimen.

The specific steps to establish a chain of custody are described in Procedure 47-3 at the end of this chapter. Because medico-legal issues are involved when handling a legal specimen, it is important to follow the procedure exactly to avoid breaking the chain. Also, because supplying a specimen for drug or alcohol testing could be incriminating to the patient, it is important to thoroughly explain the procedure to the donor and have him or her sign a consent form (Figure 47-2). The consent form may be a part of the chain-of-custody form (CCF) (Figure 47-3), or it may be a separate form. The consent form states the purpose of the test and gives you permission to collect the specimen, prepare it for transport to the laboratory for analysis, and release the results to the agency requesting the test. Distribute copies of the CCF to the medical review officer, laboratory, patient, collector, and employer or other requesting party.

Inform the patient that medication (both prescription and nonprescription), drugs, and alcohol will show up in the test results. Encourage the patient to list on the consent form or CCF all substances consumed in the last 30 days, including what was taken and how much.

The CCF form indicates the source of the specimen. It verifies through signatures that the patient whose name is on the CCF and consent forms is the same person who provided the sealed specimen sent to the laboratory. Follow Procedure 47-3, at the end of this chapter, when collecting a urine sample for drug or alcohol testing.

CHAIN-OF-CUSTODY FORM

SPECIMEN I.D.NO:

STEP 1—TO BE COMPLETED BY COLLECTOR OR EMPLOYER REPRESENTATIVE.

Employer Name, Address, and I.D. No.: _____ OR _____ Medical Review Officer Name and Address: _____

Donor Social Security No. or Employee I.D. No.: _____

Donor I.D. verified: ☐ Photo I.D. ☐ Employer Representative _____ Signature _____

Reason for test: (check one) ☐ Preemployment ☐ Random ☐ Postaccident
☐ Periodic ☐ Reasonable suspicion/cause
☐ Return to duty ☐ Other (specify) _____

Test(s) to be performed: _____ Total tests ordered: ☐

Type of specimen obtained: ☐ Urine ☐ Blood ☐ Semen ☐ Other (specify) _____

Submit only one specimen with each requisition.

STEP 2—TO BE COMPLETED BY COLLECTOR.

For urine specimens, read temperature within 4 minutes of collection.

Check here if specimen temperature is within range. ☐ Yes, 90°–100°F/32°–38°C

Or record actual temperature here: _____

STEP 3—TO BE COMPLETED BY COLLECTOR.

Collection site _____ Address _____

City _____ State _____ Zip _____ Phone _____

Collection date: _____ Time: _____ ☐ a.m. ☐ p.m.

I certify that the specimen identified on this form is the specimen presented to me by the donor identified in step 1 above, and that it was collected, labeled, and sealed in the donor's presence.

Collector's name: _____ Signature of collector: _____

STEP 4—TO BE INITIATED BY DONOR AND COMPLETED AS NECESSARY THEREAFTER.

Purpose of change	Released by Signature	Received by Signature	Date
A. Provide specimen for testing			
B. Shipment to Laboratory			
C.			

Comments: _____

STEP 5—TO BE COMPLETED BY THE LABORATORY.

Specimen package seal(s) intact when received in lab? ☐ Yes ☐ No If no, explain. _____

Laboratory receiver's initials _____

Copy 1 - Original - Must accompany specimen to laboratory.

FIGURE 47-3 The chain-of-custody form provides documentation that specific specimen collection safeguards have been followed.

Preservation and Storage

Proper specimen preservation and storage are essential. Changes that can affect the physical, chemical, and microscopic properties of urine, and invalidate certain test results, occur in urine kept at room temperature for more than 1 hour.

Refrigeration is the most common method for storing and preserving urine. It prevents bacterial growth in a specimen for at least 24 hours. Refrigeration can cause other changes in the urine, however, that may affect the physical characteristics of sediment and specific gravity. Bringing the specimen back to room temperature before testing will correct these

problems. You can also use chemical preservatives to preserve specimens, especially 24-hour specimens or those that must be sent a long distance to a laboratory.

► Urinalysis

LO 47.3

Urinalysis is the evaluation of urine by various types of testing methods to obtain information about body health and disease. Urinalysis consists of three types of testing:

- Physical
- Chemical
- Microscopic

There are normal values for all tests done on urine. The normal value for a specific substance may be negative or none, “normal,” or a range in concentration. Urine test results within normal ranges indicate health and normality. Table 47-2 identifies normal values for a variety of urine tests.

TABLE 47-2 Standard Urine Values			
Physical Characteristics		Microscopic Examination	
Test	Normal Values	Test	Normal Values
Color	Pale yellow to yellow	Epithelial cells	
Clarity	Clear to slightly turbid	Renal	Negative
Reagent Strip Test		Squamous, adult females	Moderate
Bilirubin	Negative	Squamous, adult males	Few
Blood	Negative	Transitional	Rare
Glucose	Negative	Mucus	Rare–few
Ketone bodies (acetone)	Negative	Protozoa	Negative
Leukocytes	Negative	Red blood cells	0–3/high-powered field
Nitrites	Negative	White blood cells	0–8/high-powered field
pH	4.5–8.0	Yeast	Few
Protein	Negative to trace	24-Hour	
Specific gravity	1.002–1.028*	5-HIAA	2–8 mg
Urobilinogen	0.3–1.0 E.U.	Albumin (quantitative)	10–140 mg/L
Microscopic Examination		Ammonia	140–1,500 mg
Bacteria	Negative	Calcium (quantitative)	100–300 mg
Casts		Catecholamines, total	<100 mcg
Epithelial cell	Negative	Chloride	110–120 mEq
Granular	Negative	Cortisol	10–100 mcg
Hyaline	Few	Creatine, nonpregnant women/ men	<100 mg
Red blood cell	Negative	Creatine, pregnant women	≤ 12% of creatinine
Waxy	Negative	Creatinine, men	1.0–1.9 g
White blood cell	Negative	Creatinine, women	0.8–1.7 g
Crystals		Cystine and cysteine	<38.1 mg
Amorphous phosphates	Normal	Glucose, quantitative	50–500 mg
Calcium carbonate	Normal	Phosphorus	0.4–1.3 g
Calcium oxalate	Normal	Potassium	25–120 mEq/L
Cholesterol	Negative	Protein (Bence Jones)	Negative
Cystine	Negative	Sodium	80–180 mEq
Leucine	Negative	Urea nitrogen	6–17 g
Sulfonamide	Negative	Uric acid	0.25–0.75 g
Triple phosphate	Normal	Urobilinogen, quantitative	1.0–4.0 mg
Tyrosine	Negative	Volume, adult females	600–1,600 mL
Uric acid	Normal	Volume, adult males	800–1,800 mL
		Volume, children	3–4 times adult rate/kg

Note: Individual laboratories may have slightly different reference values. Consult the reference values provided by the lab performing the test.

* Specific gravity is a physical property of urine.

Urinalysis is done as part of a general physical exam to screen for certain substances or to diagnose various medical conditions (Table 47-3). For example, daily urine output provides a picture of renal function. With adequate fluid intake, the average adult daily urine output is 1,250 milliliters, or approximately 5 cups per 24 hours. When total intake and output

measurements are not approximately equal, urinary tract dysfunction may be the cause.

The urinary system works with other body systems to help the body function normally. So a disorder in another body system can affect urinary function. For example, the kidneys interact with the nervous system to help regulate blood

TABLE 47-3 Common Urine Tests According to Clinical Condition

Clinical Condition or Suspected Disease	Types of Urine Testing
Acidosis	Reagent strip* for pH
	Specific gravity
Alkalosis (metabolic, respiratory)	Reagent strip* for pH
	Specific gravity
Diabetes mellitus	Odor (fruity)
	Microscopic examination for fatty, waxy casts
	Reagent strip* for ketonuria and glycosuria
	Specific gravity
Drug abuse	Gas chromatography
	Mass spectrometry**
Genitourinary infections (prostatitis, urethritis, vaginitis)	Cultures for bacteria, yeasts, and parasites
	Microscopic examination for bacteria and RBCs
Human immunodeficiency virus (HIV)	Culture for virus (antibiotic added to kill bacteria)
	Other tests as indicated by specific symptoms
Hypercalcemia	Microscopic examination for calcium oxalate crystals
	Specific gravity
Hypertension	Microscopic examination for casts (hyaline, RBC)
	Specific gravity
Infectious diseases (bacteria) or other inflammatory diseases	Color and odor
	Cultures for bacteria, yeasts, and viruses
	Microscopic examination for bacteria and WBCs
	RBC casts (in severe cases)
	Reagent strip* for bacteria
	Turbidity
Metabolic disorders (except diabetes mellitus)	Color
	Microscopic examination for cystine crystals
	Reagent strip* for ketonuria, fructosuria, galactosuria, pentosuria, and pH
Nephron disorders (nephrotic syndrome, glomerulonephritis, nephrosis, nephrolithiasis, pyelonephritis)	Color
	Microscopic examination for casts (epithelial, fatty, waxy, RBC) and RBCs
	Reagent strip* for proteinuria
	Specific gravity
	Turbidity
Phenylketonuria	Color
	Reagent strip* for pH

(Continued)

TABLE 47-3 Common Urine Tests According to Clinical Condition

Clinical Condition or Suspected Disease	Types of Urine Testing
Poisoning (arsenic, cadmium, lead, mercury)	Color
	Mass spectrometry**
Polycystic kidney disease	Proteinuria
	Urinary volume
Pregnancy	Reagent strip* for human chorionic gonadotropin (HCG)
Renal infections (acute glomerulonephritis, nephrotic syndrome, pyelonephritis, pyogenic infection)	Color
	Microscopic examination for epithelial cells (especially with tubular degeneration), numerous casts (granular, hyaline, WBC), RBCs, and WBCs
	Radioimmunoassay (RIA)**
	Reagent strip* for bacteria, albumin
	Specific gravity
	Turbidity
	Urinary volume
Renal disease, renal failure, severe renal damage, acute renal failure, renal tubular degeneration	Microscopic examination for epithelial cells (especially with tubular degeneration) and numerous casts (hyaline, fatty, waxy, RBC)
	Reagent strip* for proteinuria (albumin), pH
	Specific gravity
	Turbidity
	Urinary volume
Sickle cell anemia	RBC casts
Starvation, dietary imbalance, extreme change in diet, dehydration	Color
	Odor (fruity)
	Reagent strip* for ketonuria
	Specific gravity
Urinary tract infection or mild inflammation (cystitis, pyelonephritis)	Color and odor
	Cultures for bacteria, yeasts, and viruses
	Microscopic examination for bacteria, WBC casts, RBCs, and WBCs
	Reagent strip* for bacteria, albumin, and pH
	Specific gravity
	Turbidity
Urinary obstruction (tumor, trauma, inflammation)	Color
	Microscopic examination for RBCs
	Specific gravity
	Urinary volume

*Federal listings of waived tests refer to these as *dipstick tests*.

**Drug screening and some other common urine tests must be performed by a forensic laboratory or other laboratory capable of performing gas chromatography, mass spectrometry, and radioimmunoassay.

pressure and control urination. Thus, a nervous system disorder can affect the circulatory and urinary systems. The cardiovascular system delivers blood to the kidneys for filtration, and the kidneys regulate fluid balance, which helps maintain circulation of blood and myocardial function. A cardiovascular system disorder can allow blood to be delivered to the kidneys at a pressure inadequate for filtration, which would affect urinary system function.

Physical Examination and Testing of Urine Specimens

After confirming that the specimen is properly labeled, the first step in urinalysis is the visual examination of physical characteristics. As part of quality assurance, examine it to make sure there is no visible contamination and that no more than 1 hour has passed since collection (or since a refrigerated

TABLE 47-4 Urine Color and Turbidity: Possible Causes

Color and Turbidity	Pathologic Causes	Other Causes
Colorless or pale straw color (dilute)	Diabetes, anxiety, chronic renal disease	Diuretic therapy, excessive fluid intake (water, beer, and/or coffee)
Cloudy	Infection, inflammation, glomerular nephritis	Vegetarian diet
Milky white	Fats, pus	Amorphous phosphates, spermatozoa
Dark yellow, dark amber (concentrated)	Acute febrile disease, vomiting or diarrhea (fluid loss or dehydration)	Low fluid intake, excessive sweating
Yellow-brown	Excessive RBC destruction, bile duct obstruction, diminished liver cell function, bilirubin	Drugs (primaquine)
Orange-yellow, orange-red, orange-brown	Excessive RBC destruction, diminished liver cell function, bile, hepatitis, urobilinuria, obstructive jaundice, hematuria	Drugs (such as pyridium, rifampin), dyes
Salmon pink	No pathologic cause	Amorphous urates
Cloudy red	RBCs, excessive destruction of skeletal or cardiac muscle	None
Bright yellow or red	RBCs (hemorrhage, myoglobin, hemoglobin), excessive destruction of skeletal or cardiac muscle, porphyria	Beets, drugs (such as phenazopyridine hydrochloride), dyes (such as food coloring and contrast media)
Dark red, red-brown	Porphyria, RBCs (menstrual contamination, hemorrhage, hemoglobin), blood from previous hemorrhage	Menstrual contamination
Green, blue-green	Biliverdin, <i>Pseudomonas</i> organisms, oxidation of bilirubin	Vitamin B, methylene blue, asparagus (for green)
Green-brown	Bile duct obstruction	Drugs (cascara)
Brownish black	Methemoglobin, melanin	Drugs (levodopa)
Dark brown or black	Acute glomerulonephritis	Drugs (nitrofurantoin, chlorpromazine, iron preparations)

sample was brought back to room temperature). You will examine these physical characteristics:

- Color and turbidity
- Volume
- Odor
- Specific gravity

Color and Turbidity Normal urine ranges from pale yellow (straw-colored) to dark amber. The color, which comes from a yellow pigment called *urochrome*, depends on food and fluid intake, medications (including vitamin supplements), and waste products present in the urine. In general, a pale color indicates dilute urine and a dark color indicates concentrated urine.

Assess urine for turbidity, or cloudiness, by noting whether the urine is clear, slightly cloudy, cloudy, or very cloudy. Typically, urine is clear, although cloudy urine does not always indicate an abnormal condition.

The color of urine and any turbidity present can reveal medical conditions that require treatment. Table 47-4 provides more information on variations in urine color and turbidity and the possible causes or sources of these variations. Both pathologic (resulting from disease) and nonpathologic causes are noted.

Volume Normal urine volume, or output, varies according to the patient's age. Normal adult urine volume is 600 to 1,800 milliliters per 24 hours (average of 1,250 milliliters per 24 hours). Infants and children have smaller total urine volumes,

although they produce more urine per unit of body weight. Urine volume is typically measured on a timed specimen (such as a 24-hour urine specimen) rather than a random specimen.

Oliguria, insufficient production (or volume) of urine, occurs in conditions such as dehydration, decreased fluid intake, shock, and renal disease. The absence of urine production is called **anuria**. Renal or urethral obstruction and renal failure can cause anuria.

Odor Although urine odor is not typically recorded or considered a significant indicator of disease, it can provide clues about the body's condition. The odor of normal, freshly voided urine is distinct but not unpleasant and is sometimes characterized as aromatic. After urine has been standing for a while, bacteria in the specimen decompose the urea, which causes an odor similar to ammonia.

Diseases, the presence of bacteria, and particular foods (such as asparagus and garlic) can cause changes in urine odor. For example, in the presence of urinary tract infections, urine is foul-smelling, and in patients with uncontrolled diabetes, the smell is characterized as fruity (because of the presence of ketones). Phenylketonuria, a congenital metabolic disease, produces a strange, "mousy" or "musty" odor in an infant's wet diaper.

Specific Gravity Urine specific gravity is a measure of the concentration or amount of substances dissolved in urine. Because the kidneys remove metabolic wastes and other substances from the blood, the specific gravity of the urine they

produce is an indicator of the body's water balance and/or kidney function. The physician's office laboratory uses one of these two methods to determine specific gravity:

1. Refractometer
2. Reagent strip (dipstick)

Specific gravity is a relative measure that is always compared to a standard. The standard for liquids is distilled water, which contains no dissolved substances.

$$\text{Specific gravity} = \frac{\text{Weight of sample}}{\text{Weight of distilled water}}$$

The specific gravity of distilled water is 1.000. You use special equipment to test for specific gravity (Figure 47-4).

The normal range of urine specific gravity is 1.002 to 1.028. Specific gravity fluctuates throughout the day in response to fluid intake. For example, a first morning urine specimen normally has a higher specific gravity than a specimen provided later in the day. An increase in urine specific gravity may indicate that the kidneys cannot properly dilute the urine. The urine then becomes more concentrated, causing it to darken. Increased specific gravity may indicate conditions such as a urinary tract infection, dehydration (for example, from fever, vomiting, or diarrhea), adrenal insufficiency, hepatic disease, or congestive heart failure.

A decrease in the specific gravity of urine causes a lighter than normal urine color, may indicate that the kidneys cannot properly concentrate the urine, and may suggest conditions such as overhydration (excess fluid in the body), diabetes insipidus, chronic renal disease, or systemic lupus erythematosus.

Refractometer Measurement A **refractometer** is an optical instrument that measures the refraction, or bending, of light as it passes through a liquid. The degree of refraction, or refractive index, is proportional to the amount of dissolved material in the liquid. You must calibrate a refractometer each day with distilled water by setting the instrument at 1.000 with the set screw. Two standard solutions (solutions of known specific gravity) also are used to ensure accuracy. Advantages of using a refractometer to measure urine specific gravity are that the process takes little time and requires little urine. Only a drop of urine is used for this determination. Procedure 47-4, at the end of this chapter, describes how to measure specific gravity with a refractometer.

Reagent Strip Measurement You may use special reagent strips, or dipsticks, to test for specific gravity. Test

FIGURE 47-4 Specific gravity is commonly determined using a refractometer or reagent strips.

© Leesa Whicker

pads along these plastic strips contain chemicals that react with substances in the urine and change color in precise ways. The reagent strip container includes a color chart for interpreting color changes on the test pads. When you evaluate urine specific gravity in this way, keep in mind that this type of test depends on precisely timed intervals identified by the manufacturer. Follow all directions exactly. Procedure 47-5, at the end of this chapter, describes how to perform a reagent strip test.

Chemical Testing of Urine Specimens

As a medical assistant, you may be asked to perform chemical tests on urine. Prior to performing chemical tests, always check for proper identification on the urine specimen to be tested. Chemical testing is usually done with reagent strips. It also can be performed with certain automated machines that use photometry.

The licensed practitioner orders chemical testing of urine to determine the status of body processes such as carbohydrate metabolism, liver or kidney function, or acid-base balance. Other reasons for chemical testing include determining the presence of drugs, toxic environmental substances, or infections.

Testing with Reagent Strips As already described in the discussion of specific gravity, reagents (on plastic strips) are chemicals that react with a particular substance in urine and change color in precise ways. These changes indicate the presence of that substance and its amount or concentration in the urine specimen. For example, when a reagent strip is used to test for ketones, the reacted color on the strip will correspond either to a specific concentration of ketone bodies, such as acetoacetic acid, or to the absence of ketones.

Reagent strips are used to test urine for a number of substances. In addition to ketones, reagent strips test for nitrite, pH, blood, bilirubin, glucose, specific gravity, protein, and leukocytes.

There are numerous trade names for urine reagent strips (for example, Multistix® and Chemstrip®). Because not all reagents are reactive for the same chemicals, you must choose the appropriate strip according to the chemical test requested. All reagent strips are used once and discarded.

Follow the exact directions that come with the reagent strips to ensure accurate results. For quality assurance, take these basic precautions: Keep strips in tightly closed containers in a cool, dry area. Never remove them from the container until immediately before testing. Never touch the pads on the strip with your fingers or gloved hands. Examine strips for discoloration before use; discard discolored strips. Check the expiration date on the bottle; do not use strips that have expired. Use strips within 6 months of opening the container. Every time you open a new supply of reagents, run control samples to check for proper operation. Write the date opened on the bottle.

Although the process is essentially the same for all reagent strip tests, there are variations in time intervals before reading

results. Some reagent strips are designed to test for several substances at once. The basic procedure for using reagent strips for chemical tests can be found in Procedure 47-5 at the end of this chapter. In some cases, if the reagent strip test is positive, a confirmatory test is performed to ensure the accuracy of the results.

Ketone Bodies Ketone bodies (or ketones) are produced by the liver from fatty acids during fat metabolism. They include acetone, acetoacetic acid, and betahydroxybutyric acid. Only the first two substances can be determined using a reagent strip test. Normally, there are no ketones in urine. The presence of ketones in the urine may indicate that a patient is following a low-carbohydrate diet, or it may indicate that the patient has a condition such as starvation, excessive vomiting, or diabetes mellitus. Because ketones evaporate at room temperature, be sure to test urine immediately or cover the specimen tightly and refrigerate it until testing can be done.

pH Urinary pH is a measure of the urine's degree of acidity or alkalinity. Determination of pH can provide information about a patient's metabolic status and diet, the medications being taken, and several conditions. The normal pH of freshly voided urine ranges from 4.5 to 8.0. The average urine pH is 6.0, which is slightly acidic. A pH of 7.0 is neutral, a lower pH is acidic, and a higher one is alkaline. Patients with excessively alkaline urine may have conditions such as urinary tract infection or metabolic or respiratory alkalosis. Those with excessively acidic urine may have conditions such as phenylketonuria or acidosis. Reagent strip tests on both urine and blood are used to measure pH in the body. (See the *Collecting, Processing, and Testing Blood Specimens* chapter for information on blood tests for pH.)

Blood A patient who has blood in the urine may be menstruating, have a urinary tract infection, or have trauma or bleeding in the kidneys. To test for blood in urine, use a reagent strip that reacts with hemoglobin. There are two indicators on the strip: One is for nonhemolyzed blood, the other for hemolyzed blood.

Colors on the strip range from orange through green to dark blue and may indicate **hematuria** (the presence of blood in the urine) caused by cystitis; kidney stones; menstruation; or ureteral, bladder, or urethral irritation. The presence of free hemoglobin in the urine is known as *hemoglobinuria*, a rare condition caused by transfusion reactions, malaria, drug reactions, snakebites, or severe burns. Injured or damaged muscle tissue—as occurs in crushing injuries, myocardial infarction, muscular dystrophy, or contact sports injuries—can cause *myoglobinuria* (the presence of myoglobin in the urine). Reagent strip testing does not distinguish between these two conditions.

Bilirubin and Urobilinogen When hemoglobin breaks down, it converts into conjugated bilirubin in the liver and then to urobilinogen in the intestines. Presence of the bile pigment bilirubin in the urine (*bilirubinuria*) is one of the first signs of liver disease or conditions that involve the liver. When bilirubin is present, urine turns yellow-brown to greenish orange. You usually use a reagent strip to test for bilirubin. If the reagent strip test is positive, a confirmatory test called an Ictotest® is usually performed. The Ictotest® is a reagent tablet test that is more sensitive than the reagent strip test.

Although **urobilinogen** is normally present in the urine in small amounts, elevated levels may indicate increased red blood cell destruction or liver disease. Lack of urobilinogen in the urine may suggest total bile duct obstruction, as a result of which urobilinogen is not formed in the intestines or reabsorbed in the circulation. To test for urobilinogen, you use reagent strips.

Testing for either bilirubin or urobilinogen must be performed on a fresh urine specimen. Bilirubin decomposes rapidly in bright light to form biliverdin, which is not detected by the reagent strip test for bilirubin. Urobilinogen breaks down to urobilin on standing.

Glucose Glucose is normally present in urine, but only in small quantities not detectable by the reagent strip test for glucose. **Glycosuria** (the presence of significant glucose in the urine) is common in patients with diabetes. Blood is more commonly tested for glucose than urine is, because reagent strip tests may show false-negative results when used for testing urine.

Protein Although a small amount of protein is excreted in the urine every day, an excess of protein in the urine (**proteinuria**) usually indicates renal disease. Proteinuria is also common in pregnant patients and after heavy exercise.

Nitrites Bacteria in urine makes an enzyme that changes urine nitrates to nitrites. If nitrites are found in the urine, it suggests a bacterial infection of the urinary tract. The test is not definitive, however. If an insufficient number of bacteria are present in the urine or if the urine has not incubated long enough in the bladder for a reaction to take place, the nitrite test result may be falsely negative. The best urine specimen to test for nitrites is the first morning specimen.

When testing for urinary nitrites, you must test the urine immediately or refrigerate the specimen. Bacteria can multiply in a specimen allowed to sit at room temperature, causing a false-positive test result. Bacteria also can further metabolize the nitrites already produced, causing a false-negative result.

Leukocytes Leukocytes (white blood cells) appear in the urine in urinary tract or renal infections. Use strip tests for leukocyte esterase, a chemical seen when leukocytes are present, to test for leukocytes.

Other Types of Chemical Testing Other types of chemical tests—such as those that test for electrolytes and osmolality—may be performed on urine specimens. Because these tests are performed in an outside laboratory rather than in a physician's office laboratory, you do not need to know the steps in each procedure.

Phenylketones The presence of phenylketones in a patient's urine indicates phenylketonuria (PKU), a genetically inherited disorder in which the body cannot properly metabolize the nutrient phenylalanine. This rare disorder causes phenylalanine to build up in the body, resulting in mental retardation. PKU can be treated successfully by limiting the dietary intake of phenylalanine, which makes up 5% of all natural protein, from early infancy. Although urine can be tested

for the presence of phenylketones, blood testing is routine for newborns before discharge, at least 24 hours after birth.

Pregnancy Tests Pregnancy testing is based on detecting the hormone—called *human chorionic gonadotropin*, or *HCG*—secreted by the placenta. HCG levels vary throughout pregnancy: They usually peak at about 8 weeks, drop to lower levels in the second trimester, and then rise to detectable levels in the last trimester. Many commercial pregnancy tests are manufactured for use both in the clinical setting and at home. These tests are sensitive, are easy to perform and interpret, and give quick results. Most tests are now designed as an enzyme immunoassay (EIA) test, which involves an antigen, an antibody specific for the antigen, and a second antibody conjugated to an enzyme. Newer technologies called *membrane EIAs* have been developed; in these tests, most of the reagents are incorporated into an absorbent membrane in a plastic case. A sample of either urine or serum is added through a chamber window, where it migrates through the membrane and combines with the reagents to produce a reaction. Although the technology used in the design of these tests is quite complex, the test itself is easy to set up and interpret (see Procedure 47-6 at the end of this chapter). The tests are all designed with a control feature incorporated into the reagent pack for quality assurance of the test results.

Urine Tests for the Presence of STIs In response to increasing numbers of sexually transmitted infections, the CDC recommends that all sexually active females between the ages of 15 and 25 be screened annually for chlamydia. To accomplish this, several tests called *nucleic acid amplification tests (NAATs)* have recently been developed. These tests utilize urine samples to detect the presence of nucleic acid. Patients infected with either *Chlamydia trachomatis* or *Neisseria gonorrhoeae* will have nucleic acid in their urine. By amplifying nucleic acids specific to chlamydia and gonorrhea, the test can detect the presence of very small numbers of bacteria.

These tests have several advantages:

- Sample collection is noninvasive and the sample is easily collected.
- The tests are highly specific.
- The tests are highly sensitive. As little as one copy of bacterial nucleic acid can be detected in a urine specimen.
- Organisms do not have to be living to be detected.
- The tests are good screening tools for asymptomatic patients.

The tests also have some disadvantages:

- The tests are expensive.
- No living organisms remain for use in a follow-up culture, so positive tests must be confirmed by culture from an endocervical or urethral swab.

Microscopic Examination of Urine Specimens

A microscopic examination of urine sediment is typically done by the licensed practitioner to view elements only visible with a microscope. You will use a centrifuge to obtain sediment for analysis. A centrifuge spins test tubes containing fluid at speeds that cause heavier substances in the fluid to settle to the bottom of the tubes.

The substances in urine that form sediment (precipitate) when urine is centrifuged include cells, casts, crystals, yeast, bacteria, and parasites. These elements are categorized and counted during microscopic examination. You may use the KOVA System®, manufactured by Hycor Biomedical, Irvine, California, to prepare urine sediment for microscopic examination. When you use the KOVA System®, the sediment is evenly distributed to four calibrated chambers before the microscopic elements are counted. Procedure 47-7, at the end of this chapter, describes how to process a urine specimen for microscopic examination of sediment.

Cells High-power magnification is used to classify and count cells. Three types of cells may be found in urine (Figure 47-5):

- Epithelial cells
- White blood cells
- Red blood cells

Epithelial Cells Epithelial cells are classified as renal, transitional, or squamous. Renal epithelial cells can be round to oval and have a large, oval, and sometimes eccentric nucleus. Although a few of these cells appear normally in urine, several may indicate tubular damage in the kidneys. Damage in the renal tubules causes epithelial cells to die and slough off, or shed. These shed cells can then be seen in a urine sample.

Transitional epithelial cells line the urinary tract from the renal pelvis (the beginning of the ureter) to the upper portion of the urethra. They can be round to oval and may have a tail and, occasionally, two nuclei. Like the renal epithelial cell, a few appear normally in urine, but several may indicate tubular damage.

Squamous epithelial cells—large, flat, irregular cells with a small, round, centrally located nucleus—line the genitourinary tract's lower portion. They often occur in sheets or clumps and can be easily recognized under low-power magnification.

White Blood Cells White blood cells (WBCs) are larger than red blood cells, have a granular appearance, and usually contain a multilobed nucleus. They are typically found in large numbers in the urine (greater than the normal zero to eight per high-power field) if inflammation is present or if the specimen was contaminated during collection.

Red Blood Cells Red blood cells (RBCs) are typically pale, round, nongranular, and flat or biconcave. They have no nucleus and enter the urinary tract during inflammation or injury. From zero to three RBCs per high-power field in urine are normal. However, numerous RBCs may indicate a variety of problems, including urinary infection, obstruction, inflammation, trauma, or tumor.

FIGURE 47-5 Cells that may be seen in urine during microscopic analysis.

Casts Casts—cylinder-shaped elements with flat or rounded ends—form when protein from the breakdown of cells accumulates and precipitates in the kidney tubules and is washed into the urine. The protein then assumes the size and shape of the tubules. Think of a clogged drain in your bathroom sink. The drain may start out just slow at first but, after

a while, very little water will pass through. If you remove the drain pipe, you will find that the material plugging up the drain has taken on the shape of the pipe. It works the same in the kidney tubules, but with different materials. Casts differ in composition and size (Figure 47-6). Classified according to their appearance and composition, casts can indicate renal

FIGURE 47-6 Casts, which are shaped like cylinders with flat or rounded ends, are formed when protein accumulates in the kidney tubules and is washed into the urine.

pathologic conditions or can be caused by strenuous exercise. Types of casts include

- **Hyaline casts**, which are pale, transparent, and cylinder-shaped with rounded ends and parallel sides. Composed of protein, they form because of diminished urine flow through individual nephrons. They are present in patients with kidney disease or in people who have exercised strenuously. A few hyaline casts observed in the urine is normal.
- **Granular casts**, which resemble hyaline casts and can result from kidney disease or strenuous exercise.
- **Red blood cell casts**, which always indicate an abnormality and are hyaline casts with embedded red blood cells. Because of the RBCs, these casts sometimes appear brown.
- **White blood cell casts**, which are hyaline casts with leukocytes. These casts typically have a multilobed nucleus and may indicate pyelonephritis—an inflammation of the kidney and renal pelvis.
- **Epithelial cell casts**, which contain embedded renal tubular epithelial cells and indicate excessive kidney damage. Causes include shock, renal ischemia, heavy-metal poisoning, certain allergic reactions, and nephrotoxic drugs. These casts are often confused with white blood cell casts.
- **Waxy casts**, which are rare, yellow, glassy, brittle, smooth, and homogeneous structures with cracks or fissures and squared or broken ends. These casts occur with severe renal disease.

Crystals Crystals, naturally produced solids of definite form, are commonly seen in urine specimens, especially those permitted to cool. They usually do not indicate a significant disorder, except when found in large numbers in patients with kidney stones and in a few pathologic conditions (such as hypercalcemia and some inborn errors of metabolism). Figure 47-7 shows crystals commonly found in urine specimens. Because different substances tend to crystallize in acidic and alkaline urine, it is important to determine the pH of a patient's urine before you try to identify any present crystals.

Yeast Cells Yeast cells, which are usually oval and may show budding, may be confused with RBCs. Yeast cells in urine sediment are associated with genitourinary tract infection, external genitalia contamination, vaginitis, urethritis, and prostatitis. These cells are also commonly seen in the urine of patients with diabetes.

Bacteria Although a few bacteria are normally found in urine, urinary tract infection may be indicated if the urine has bacteria along with a putrid odor and numerous white blood cells. Bacteria under high-power magnification appear rod- or cocci-shaped (spherical).

Parasites The presence of parasites in sediment may signal genitourinary tract infection or external genitalia contamination. The most common urinary parasite, *Trichomonas vaginalis* (a pear-shaped protozoan with four flagella), is typically found in vaginal disorders but also may appear in males. When a urine specimen is cooled, *Trichomonas* organisms die.

Urine Culture and Sensitivity

If a patient is suspected of having a complicated urinary tract infection, or if a urinalysis shows bacteria in the patient's urine, a **urine culture** may be performed. For this test, a clean-catch urine specimen is usually required. The urine is placed on a growth medium, and bacteria are allowed to grow for 24 to 48 hours. Any large growths of bacteria are then identified. A sensitivity or susceptibility test may then be performed, in which the bacteria are cultured in the presence of several different antibiotics. The antibiotic that best inhibits the growth of the bacteria is considered the best choice for treating the infection.

▶ Collecting and Processing Stool Specimens

LO 47.4

If the licensed practitioner suspects that the patient has certain diseases, such as cancer or colitis, or bacterial, protozoal, or parasitic infections, you may need to obtain stool specimens. The collection technique varies with the suspected microorganism. Although both you and the patient may be embarrassed to discuss instructions for collecting stool specimens, do not let this interfere with proper specimen collection. For more information about stool sample collection, see the feature *Educating the Patient: Collecting a Stool Sample*.

Screening for Colorectal Cancer

The **fecal occult blood test (FOBT)** is a test for hidden (occult) blood in the stool. The presence of blood in the stool may indicate colorectal cancer, though other diseases and disorders, such as hemorrhoids and gastric ulcers, also may cause blood in the stool. Some food—such as broccoli and beets—and drugs—such as aspirin and ibuprofen—may cause a false-positive test. It is important that you explain to the patient the importance of following all pretest dietary and medication instructions. The test is fast, easy, and inexpensive, making it a good choice for colorectal screening. The test also may be used to determine the cause of anemia. A positive test warrants further investigation for the cause of the bleeding, including colonoscopy, blood tests, and other diagnostic imaging studies such as upper endoscopy or CT scan. Procedure 47-8 at the end of this chapter, outlines the steps in fecal occult blood testing using the guaiac testing method.

Suspected Bacterial Infection

Bacterial infections caused by species of the *Shigella* or *Salmonella* genus can cause loose, bloody, or mucus-tinged stools. A licensed practitioner who suspects that a patient has one of these types of infections may request that a stool specimen be obtained for culture.

Successful recovery of these pathogenic bacteria from a stool specimen depends on timely inoculation of special culture media. The licensed practitioner may ask the patient to provide a sample in the office whenever possible to avoid delay in processing the specimen. Several types of culture media promote the growth of intestinal pathogens while suppressing the growth of other microorganisms.

FIGURE 47-7 Common urine crystals.

Suspected Protozoal or Parasitic Infection

In cases of a suspected protozoal or parasitic infection, the licensed practitioner may request an **O&P specimen**, short for *ova and parasites specimen*. This type of stool sample is examined for the presence of certain forms of protozoans or parasites, including their eggs (ova).

When a practitioner requests an O&P test, obtain both a fresh and a preserved stool specimen. A fresh specimen is examined both macroscopically and microscopically for the presence of microorganisms. A preserved specimen is also necessary because certain forms of these organisms are destroyed within a short time after leaving the body and may

EDUCATING THE PATIENT

Collecting a Stool Sample

Patients must collect stool specimens properly so that they are not contaminated with urine or water from the toilet, both of which can lead to inaccurate results. If the sample is contaminated, it will have to be collected again.

There are a number of ways a patient can collect a stool specimen. What works for one patient may not work for another. Obtaining stool specimens from young children also can be challenging. Educate patients to collect samples in one of the following ways:

- On a clean paper plate
- In a clean waxed-paper carton
- In a clean plastic or glass container
- On collection tissue that you provide
- On plastic wrap draped loosely over the back half of the toilet seat with enough material to form a collection pocket in the middle

- In a plastic hat-like device placed on the toilet under the seat or placed underneath a child
- In a child's diaper lined with plastic positioned toward the back and rolled up to make a dam, which helps keep urine from contaminating the sample

After collecting the sample, have the patient

- Use a tongue depressor to place a portion of the sample in a specimen container with a tight-fitting lid.
- Transport the specimen to the office or laboratory as soon as possible.
- Refrigerate the specimen if transport will be delayed.

not be detected in the fresh specimen. You must always obtain a preserved specimen when stool samples are sent to an outside laboratory.

Special stool collection kits are available. They contain a specimen container for a fresh sample along with vials of two types of preservatives: formalin (a dilute solution of formaldehyde) and polyvinyl alcohol (PVA). Instruct the patient to place the stool sample in the specimen container and to mix portions of the specimen in each of the preservative vials. The laboratory will examine all specimens for the presence of microorganisms.

When a licensed practitioner suspects that a patient has a protozoal or parasitic infection, he will request that a series of at least three stool specimens be examined. Three specimens are required because different forms of the microorganism may be present in the stool at different times, and some could be missed with only one sample. Because certain medications can interfere with detecting these microorganisms, the patient may be asked to refrain from using medications such as anti-diarrheal compounds, antacids, and mineral oil laxatives for at least a week before samples are obtained.

PROCEDURE 47-1 Collecting a Clean-Catch Mid-Stream Urine Specimen **WORK // DOC**

Procedure Goal: To collect a urine specimen that is free from contamination

OSHA Guidelines:

Materials: Dry, sterile urine container with lid; label; written instructions (if the patient is to perform procedure independently); and antiseptic towelettes, laboratory requisition form, patient chart/progress note

Method:

1. Confirm the patient's identity and be sure all forms are correctly completed.
2. Label the sterile urine specimen container with the patient's name, ID number, and date of birth; the

licensed practitioner's name; the date and time of collection; and the initials of the person collecting the specimen.

When the Patient Will Be Completing the Procedure Independently

3. Explain the procedure in detail. Provide the patient with written instructions, antiseptic towelettes, and the labeled sterile specimen container.
4. Confirm that the patient understands the instructions, especially not to touch the inside of the specimen container and to refrigerate the specimen until bringing it to the licensed practitioner's office.

RATIONALE: *Touching the inside of the container will introduce microorganisms into the container and can interfere with the test results. The specimen should be refrigerated to keep bacteria from growing and causing a false-positive result.*

When You Are Assisting a Patient

3. Explain the procedure and how you will be assisting in the collection.
4. Wash your hands and don exam gloves.

When You Are Assisting in the Collection for Female Patients

5. Remove the lid from the specimen container and place the lid upside down on a flat surface.
6. Use three antiseptic towelettes to clean the perineal area by spreading the labia and wiping from front to back. Wipe with the first towelette on one side and discard it. Wipe with the second towelette on the other side and discard it. Wipe with the third towelette down the middle and discard it. To remove soap residue that could cause a higher pH and affect chemical test results, rinse the area once from front to back with water.

RATIONALE: *The area must be thoroughly cleaned so that microorganisms from the vulva do not contaminate the specimen.*

7. Keeping the patient's labia spread to avoid contamination, tell her to urinate into the toilet. After she has expressed a small amount of urine, instruct her to stop the flow.
RATIONALE: *So that microorganisms are washed away from the urethral opening.*
8. Position the specimen container close to but not touching the patient.
9. Tell the patient to start urinating again. Collect the necessary amount of urine in the container. (If the patient cannot stop her urine flow, move the container into the urine flow and collect the specimen anyway.)
10. Allow the patient to finish urinating. Place the lid back on the collection container.

11. Remove the gloves and wash your hands.
12. Complete the test request slip and record the collection in the patient's chart.

When You Are Assisting in the Collection for Male Patients

5. Remove the lid from the specimen container and place the lid upside down on a flat surface.
6. If the patient is circumcised, use an antiseptic towelette to clean the head of the penis. Wipe with a second towelette directly across the urethral opening. If the patient is uncircumcised, retract the foreskin before cleaning the penis. To remove soap residue that could cause a higher pH and affect chemical test results, rinse the area once from front to back with water.

RATIONALE: *The area must be thoroughly cleaned so that microorganisms from the head of the penis do not contaminate the specimen.*

7. Keeping an uncircumcised patient's foreskin retracted, tell the patient to urinate into the toilet. After he has expressed a small amount of urine, instruct him to stop the flow.
RATIONALE: *So that microorganisms are washed away from the urethral opening.*
8. Position the specimen container close to but not touching the patient.
9. Tell the patient to start urinating again. Collect the necessary amount of urine in the container. (If the patient cannot stop his urine flow, move the container into the urine flow and collect the specimen anyway.)
10. Allow the patient to finish urinating. Place the lid back on the collection container.
11. Remove the gloves and wash your hands.
12. Complete the laboratory requisition form and record the collection in the patient's chart/progress note.

PROCEDURE 47-2 Collecting a 24-Hour Urine Specimen **WORK // DOC**

Procedure Goal: To collect a urine specimen that is free from contaminants over a 24-hour period

OSHA Guidelines:

Materials: Urine collection container (disposable urinal or collection hat), sterile urine storage containers, written instructions, laboratory requisition form, and patient chart/progress note

Method:

1. Review the laboratory requisition form and gather the supplies.
2. Confirm the patient's identity, introduce yourself, and check that all forms are completed correctly.

3. Label the sterile urine specimen storage containers with the patient's name, ID number, and date of birth and the licensed practitioner's name.
4. Explain that the urine specimen storage container may have a preservative in it. Tell the patient what to do if he gets the preservative on his skin. (Usually, flushing with cold water is sufficient; follow the manufacturer's provided instructions.)
5. Give the patient the following instructions:
 - a. At the start of the observation period (usually early in the morning), void and discard the first urine specimen. This will start the collection period. Write the start date and time on the urine specimen storage containers.

RATIONALE: *So that only the urine produced in a 24-hour period is collected.*

- b. Do not discard the preservative in the urine specimen storage container.
- c. For the next 24 hours, each time you void, collect the entire specimen in the provided specimen collection container.
- d. Carefully transfer the entire specimen in the urine storage container, being careful not to spill any urine. If the you spill urine or accidentally urinate in the toilet, call to reschedule the test.

RATIONALE: *All urine must be collected so that an accurate measure of urine components may be obtained.*

- e. Keep the specimen covered and in the refrigerator or in a cooler when not in use.
- f. Twenty-four hours after you begin the test, void once more and transfer to the specimen storage container. Write the end date and time on the container.
- g. As quickly as possible, bring the specimen back to the office or deliver it to the laboratory if instructed to do so. Keep the specimen cool during transport.

- 6. When the patient returns the urine specimen, wash your hands, don gloves, and then be sure to do the following:
 - a. Check that the container lid is secure.
 - b. Clean the outside of the container with a tissue or gauze pad if necessary.
 - c. Check that the start and end dates and times are recorded on the container.
 - d. Note the volume of the collected specimen.
 - e. Review the procedure with the patient to make sure the specimen was properly collected and stored during the collection period.
 - f. Complete the necessary laboratory requisition forms.
 - g. Notify the lab that the specimen is ready for transport.
 - h. Keep the specimen cold until it is transported to the lab.
- 7. Remove the gloves and wash your hands.
- 8. Document the specimen collection, including volume, dates and times, and lab tests requested.

PROCEDURE 47-3 Establishing Chain of Custody for a Urine Specimen

WORK // DOC

Procedure Goal: To collect a urine specimen for drug testing, maintaining a chain of custody

OSHA Guidelines:

Materials: Dry, sterile urine container with lid; chain-of-custody form (CCF); and two additional specimen containers

Method:

1. Positively identify the patient. (Complete the top part of the CCF with the drug testing laboratory's name and address, the requesting company's name and address, and the patient's Social Security number. Make a note on the form if the patient refuses to give her Social Security number.) Ensure that the number on the printed label matches the number at the top of the form.
2. Ensure that the patient removes any outer clothing and empties her pockets, displaying all items.

RATIONALE: *So that the patient does not bring anything into the room to adulterate the specimen, resulting in a false-negative result*
3. Instruct the patient to wash and dry her hands.
4. Instruct the patient that no water is to be running while the specimen is being collected. Tape the faucet handles in the off position and add bluing agent to the toilet.

RATIONALE: *So that the patient cannot warm a specimen brought in from another source and has no water available to dilute the specimen.*

5. Instruct the patient to provide the specimen as soon as it is collected so that you can record the specimen's temperature.
6. Remain by the door of the restroom.
7. Measure and record the urine specimen's temperature within 4 minutes of collection. Make a note if its temperature is out of the acceptable range.

RATIONALE: *To determine that the patient voided the specimen and did not bring it from an outside source.*
8. Examine the specimen for signs of adulteration (unusual color or odor).
9. *In the presence of the patient*, check the "single specimen" or "split specimen" box. The patient should witness you transferring the specimen into the transport specimen bottle(s), capping the bottle(s), and affixing the label on the bottle(s).

RATIONALE: *To maintain the chain of custody.*
10. The patient should initial the specimen bottle label(s) *after* it is placed on the bottle(s).

RATIONALE: *To maintain the chain of custody.*
11. Complete any additional information requested on the form, including the authorization for drug screening. This information will include the following:
 - Patient's daytime telephone number
 - Patient's evening telephone number
 - Test requested
 - Patient's name
 - Patient's signature
 - Date

12. Sign the CCF; print your full name and note the date and time of the collection and the name of the courier service.
13. Give the patient a copy of the CCF.
14. Place the specimen in a leakproof bag with the appropriate copy of the form.
15. Release the specimen to the courier service.
16. Distribute additional copies as required.

PROCEDURE 47-4 Measuring Specific Gravity with a Refractometer

WORK // DOC

Procedure Goal: To measure the specific gravity of a urine specimen with a refractometer

OSHA Guidelines:

Materials: Urine specimen, refractometer, dropper, laboratory report form, and patient chart/progress note

Method:

1. Wash your hands and don exam gloves.
2. Check the specimen for proper labeling and examine it to make sure there is no visible contamination and that no more than 1 hour has passed since collection (or since the specimen was removed from the refrigerator and brought back to room temperature).
3. Swirl the specimen.
RATIONALE: *To mix the specimen thoroughly.*
4. Confirm that the refractometer has been calibrated that day. If not, you must calibrate it with distilled water. You also must use two standard solutions as controls to check the refractometer's accuracy. Follow Steps 6 through 11, using each of the three samples in place of the specimen. Clean the refractometer and the dropper after each use and record the calibration values in the quality control log.
RATIONALE: *To ensure that the refractometer is standardized prior to testing the specimen.*
5. Open the hinged lid of the refractometer.
6. Draw up a small amount of the specimen into the dropper.
7. Place one drop of the specimen under the cover.
8. Close the lid.
9. Turn on the light and look into the refractometer's eyepiece. As the light passes through the specimen, the

refractometer measures the refraction of the light and displays the refractive index on a scale on the right, with corresponding specific gravity values on the left.

10. Read the specific gravity value at the line where light and dark meet.
11. Record the value on the laboratory report form.
12. Sanitize and disinfect the refractometer and the dropper. Put them away when they are dry.
13. Clean and disinfect the work area.
14. Remove the gloves and wash your hands.
15. Record the value in the patient's chart/progress note.

FIGURE Procedure 47-4 Step 9 A refractometer uses light refraction to measure specific gravity.

PROCEDURE 47-5 Performing a Reagent Strip Test

WORK // DOC

Procedure Goal: To perform chemical testing on urine specimens to screen for the presence of various elements, including leukocytes, nitrites, urobilinogen, protein, pH, blood, specific gravity, ketones, bilirubin, and glucose

OSHA Guidelines:

Materials: Urine specimen, laboratory report form, pipette or urinalysis transfer straw, reagent strips, paper towel, timer, and patient chart/progress note

Method:

1. Wash your hands and don personal protective equipment.
2. Check the specimen for proper labeling and examine it to make sure there is no visible contamination. Perform the test as soon as possible after collection. Refrigerate the specimen if testing will take place more than 1 hour later. Bring the refrigerated specimen back to room temperature prior to testing.

3. Check the expiration date on the reagent strip container and check the strip for damaged or discolored pads.

RATIONALE: To ensure that the reagent strip is still valid.

4. Swirl the specimen.

RATIONALE: To mix the specimen thoroughly.

5. Remove a small amount (aliquot) of the urine with a pipette or a urinalysis transfer straw and place it into a labeled secondary container.

RATIONALE: In the event that a urine culture is needed, the entire sample is not contaminated by chemicals on the reagent pads. These chemicals could interfere with a urine culture test.

Dip a urine strip into the aliquoted specimen, making sure each pad is completely covered. Briefly tap the strip sideways on a paper towel. *Do not blot* the test pads.

RATIONALE: Excess urine could migrate to the other pads and alter the test results.

6. Read each test pad against the chart on the bottle at the designated time.

Note: It is important to read each pad at the appropriate time. Most reagent strip results are invalid after 2 minutes.

FIGURE Procedure 47-5 Step 6 Read the reagent strip by the time indicated in the manufacturer's instructions.

© McGraw-Hill Education

RATIONALE: Test pads read at inappropriate times will yield inaccurate results.

7. Record the values on the laboratory report form.
8. Discard the used disposable supplies.
9. Clean and disinfect the work area.
10. Remove your gloves and wash your hands.
11. Record the result in the patient's chart/progress note.

PROCEDURE 47-6 Pregnancy Testing Using the EIA Method

WORK // DOC

Procedure Goal: To perform the enzyme immunoassay in order to detect HCG in the urine (or serum) and to interpret results as positive or negative

OSHA Guidelines:

Materials: Gloves, urine specimen, urinalysis transfer straw, timing device, surface disinfectant, pregnancy control solutions, pregnancy test kits, quality control log, and patient chart/progress note

Method:

1. Wash your hands and don exam gloves.
2. Gather the necessary supplies and equipment.
3. If materials have been refrigerated, allow all materials to reach room temperature prior to conducting the testing.
4. Label the test chamber with the patient's name or identification number; label one test chamber for a negative and positive control.
5. Apply the urine (or serum) to the test chamber per the manufacturer's instructions. A urine transfer straw may be used.

RATIONALE: Different tests may have slightly different instructions.

6. At the appropriate time, read and interpret the results.

RATIONALE: Most tests are invalid after 10 minutes.

(a)

(b)

FIGURE Procedure 47-6 Step 6 A positive pregnancy test (a) and a negative pregnancy test (b). Note that if the line does not appear in the C (Control) area, the test is invalid.

© Leesa Whicker

PROCEDURE 47-7 Processing a Urine Specimen for Microscopic Examination of Sediment

WORK // DOC

Procedure Goal: To prepare a slide for microscopic examination of urine sediment

OSHA Guidelines:

Materials: Fresh urine specimen, two glass or plastic test tubes, water, centrifuge, tapered pipette or urinalysis transfer straw, glass slide with coverslip, microscope with light source, laboratory report form, and patient chart/progress note

Method:

1. Wash your hands and don exam gloves.
2. Check the specimen for proper labeling and examine it to make sure there is no visible contamination and that no more than 1 hour has passed since collection (or since the specimen was removed from the refrigerator and brought back to room temperature).
3. Swirl the urine specimen.
RATIONALE: To mix the specimen thoroughly.
4. Use a urinalysis transfer straw to place approximately 10 mL of urine into a labeled test tube. Pour 10 mL of plain water into the balance tube.

FIGURE Procedure 47-7 Step 4 Fill one test tube with approximately 10 mL of urine and the other with 10 mL of water.

7. Document the patient's results in the patient chart/progress note: document the quality control results in the appropriate quality control log book.
8. Dispose of used reagents in a biohazard container.
9. Clean the work area with a disinfectant solution.
10. Remove your gloves and wash your hands.

5. Balance the centrifuge by placing the test tubes on opposite sides of the centrifuge.

RATIONALE: An unbalanced tube could cause the centrifuge to “walk” or wobble off the table.

FIGURE Procedure 47-7 Step 5 The centrifuge must be balanced by placing one test tube on each side.

6. Make sure the lid is secure and set the centrifuge timer for 5 to 10 minutes.

RATIONALE: Spinning the urine will force the solids (cells, casts, and crystals) to the bottom of the tube.

FIGURE Procedure 47-7 Step 6 Set the centrifuge timer for 5 to 10 minutes.

7. Set the speed as prescribed by your office’s protocol (usually 1,500 to 2,000 revolutions per minute) and start the centrifuge.

8. After the centrifuge stops, lift out the tube containing the urine and carefully pour most of the liquid portion—called the **supernatant**—down the sink drain, washing it down the drain with water.

FIGURE Procedure 47-7 Step 8 Make sure you do not lose any sediment when you pour off the urine.

9. A few drops of urine should remain in the bottom of the test tube with any sediment. Mix the urine and sediment together by gently tapping the bottom of the tube on the palm of your hand.

RATIONALE: To resuspend the solid material.

10. Use the tapered pipette or transfer straw to obtain a drop or two of urine sediment. Place the drops in the center of a clean labeled glass slide.
11. Place the coverslip over the specimen, allow it to settle, and place it on the stage of the microscope.
12. Correctly focus the microscope as directed in the *Microbiology and Disease* chapter.

Note: Most medical assistants are trained to perform this procedure only up to this point. After this, the licensed practitioner usually examines the specimen. You may, however, be asked to clean the items after the examination is completed. The remaining steps are provided for your information.

13. Use a dim light and view the slide under the low-power objective. Observe the slide for casts (found mainly around the coverslip’s edges) and count the casts viewed.
14. Switch to the high-power objective. Identify the casts. Identify any epithelial cells, mucus, protozoans, yeasts, and crystals. Adjust the slide position so that you can view and count the cells, protozoans, yeasts, and crystals from at least 10 different fields. Turn off the light after the examination is completed.
15. Record the observations on the laboratory report form.

16. Properly dispose of used disposable materials.
17. Sanitize and disinfect nondisposable items; put them away when they are dry.
18. Clean and disinfect the work area.
19. Remove the gloves and wash your hands.
20. Record the observations in the patient's chart/progress note.

PROCEDURE 47-8 Fecal Occult Blood Testing Using the Guaiac Testing Method

WORK // DOC

Procedure Goal: To test for the presence of blood in a fecal sample

OSHA Guidelines:

Materials: Fecal occult blood testing cards or slides, fecal collection spoon or other device, written patient instructions, testing reagents, and patient chart/progress note

Method:

1. Confirm the patient's identity and ensure that all forms are completed correctly.
2. Label the occult blood testing card or slide with the patient's name and date of birth. Give the patient the test card or slide and collecting spoon or applicator.
3. Give the patient pretest and collection instructions:
 - a. Do not collect a sample if you are menstruating or if visible blood is seen in the feces or toilet.
 - b. For 3 days prior to collecting the sample, avoid red meats (beef, veal, and lamb); horseradish; vitamin C supplements; certain fruits and vegetables, such as cabbage, cucumbers, broccoli, carrots, beets, radishes, mushrooms, and citrus fruits; aspirin or other nonsteroidal anti-inflammatory drugs; and other medications, including corticosteroids. (Consult the specific test instructions for dietary and medication restrictions, because these may vary from test to test.)

RATIONALE: Some foods and medications may cause a false-positive or a false-negative test result.

- c. Collect the samples (depending on the specific test) on 2 or 3 different days.
- d. Collect the specimen before it comes into contact with the toilet water. (The patient may use a clean container or a specimen collection hat.)

RATIONALE: Chemicals in the toilet could interfere with the test.

- e. Place a small amount of fecal material on each slide or test card window with the applicator. The sample should be thinly smeared in the sample area.
- f. Close the card window or place the slide in the provided container and write the collection date on the card or slide.
- g. Return the card or slide to the office.

FIGURE Procedure 47-8 Step 3e The patient should apply a thin smear of fecal material on each window of the test card.

© McGraw-Hill Education

Processing the Test

4. Wash your hands and don gloves.
5. Open the back of the card. Add the recommended amount of developing reagent directly over the smeared area on the back side of the paper and over the positive and negative controls, if present, on the card.

RATIONALE: To ensure that the test is working correctly.

6. Read the test results at the appropriate time according to the manufacturer's instructions (usually within 60 seconds). There will be a blue color on the guaiac paper if blood is present.

FIGURE Procedure 47-8 Step 6 Read the card by the time indicated in the manufacturer's instructions.

© McGraw-Hill Education

7. Dispose of the testing card according to OSHA regulations.
8. Remove your gloves and wash your hands.
9. Document the results in the patient's chart.

S U M M A R Y O F L E A R N I N G O U T C O M E S

LEARNING OUTCOMES	KEY POINTS
47.1 Discuss the role of the medical assistant in collecting, processing, and testing urine and stool samples.	Your role as a medical assistant includes collecting, processing, and testing urine samples and processing and testing stool samples. You also will be responsible for teaching patients proper collection methods for urine and stool samples.
47.2 Carry out procedures for collecting urine specimens according to guidelines.	The general guidelines for collecting a urine specimen include following the procedure specified for the urine test that will be performed; using the type of specimen container indicated by the laboratory; properly labeling the specimen container; explaining the procedure to the patient when assisting in the collection process; washing your hands before and after the procedure and wearing gloves during the procedure; and completing all necessary paperwork.
47.3 Describe the process of urinalysis and its purpose.	Urinalysis is the evaluation of urine by various types of testing methods to obtain information about body health and disease.
47.4 Carry out the proper procedure for collecting and processing a stool sample for fecal occult blood testing.	The general guidelines for collecting a stool specimen include instructing the patient about the need to follow all collection procedures, including when to collect, how to collect, and how to return the specimen to the office; following the testing procedure for fecal occult blood testing; using standard precautions when performing the test; and documenting the test and results in the patient's chart.

Recall Ken Washington from the beginning of the chapter. Now that you have completed the chapter, answer the following questions regarding his case.

1. What instructions will you give Ken in collecting the urine sample for reagent testing?
2. What tests are included in a reagent test?
3. Describe the instructions you will need to give Ken regarding his 24-hour urine collection.

E X A M P R E P A R A T I O N Q U E S T I O N S

1. (LO 47.2) Which of the following catheters is used after plastic repair of the ureter?
 - a. Indwelling
 - b. Urinary
 - c. Drainage
 - d. Splinting
 - e. Permanent
2. (LO 47.3) The average adult urinary output is
 - a. 650 mL
 - b. 1,000 mL
 - c. 1,250 mL
 - d. 1,500 mL
 - e. 2,000 mL

3. (LO 47.3) A urine sample that is turbid is said to be
 - a. Cloudy
 - b. Clear
 - c. Odorous
 - d. Dark
 - e. Dilute
4. (LO 47.3) What is the specific gravity of distilled water?
 - a. 0.00
 - b. 1.000
 - c. 1.001
 - d. 1.010
 - e. 1.100
5. (LO 47.3) Which of the following is (are) normally found in a urine sample?
 - a. Cholesterol
 - b. Tyrosine
 - c. Ketone bodies
 - d. Amorphous phosphates
 - e. Glucose
6. (LO 47.4) A test for the presence of hidden blood in a stool sample is which of the following?
 - a. SGOT
 - b. FOBT
 - c. Bilirubin
 - d. EIA
 - e. Urobilinogen
7. (LO 47.3) Calcium carbonate, calcium oxalate, and triple phosphate are types of which kind of structure sometimes present in urine?
 - a. Casts
 - b. Blood cell components
 - c. Bence Jones proteins
 - d. Vitamins
 - e. Crystals
8. (LO 47.3) Which of the following is a chemical component of urine?
 - a. Color
 - b. Volume
 - c. Blood
 - d. Ketones
 - e. Clarity
9. (LO 47.2) The most common type of urine sample is
 - a. First morning
 - b. 24-hour
 - c. Timed
 - d. Random
 - e. Mid-stream
10. (LO 47.3) The term meaning insufficient production of urine is
 - a. Anuria
 - b. Oliguria
 - c. Polyuria
 - d. Proteinuria
 - e. Hematuria

SOFT SKILLS SUCCESS

The licensed practitioner has ordered a test of stool for blood on a patient. The patient is given a home testing kit, and he will need to take three samples of stool, one on each of 3 separate days. You are teaching the patient about the procedure when, in a rough and hostile voice, he states, “There is no way I am going to collect my own s***! You can tell that doctor to forget it!” What should you do?

Go to PRACTICE MEDICAL OFFICE and complete the module Clinical - Interactions.

Collecting, Processing, and Testing Blood Specimens

CASE STUDY

PATIENT INFORMATION	Patient Name	DOB	Allergies
	Sylvia Gonzales	9/1/19XX	PCN
PATIENT INFORMATION	Attending	MRN	Other Information
	Alexis N. Whalen, MD	341-73-792	Vital Signs: BP 136/86, T 97.6, P 92, R 20

Sylvia Gonzales, a 51-year-old female, is at the office for a 3-month return check for her newly diagnosed Type 2 diabetes. She states that she has taken the medication she received for her “sugar” and she knows the doctor wants to do a special “sugar test” this time. Her medication

© McGraw-Hill Education

list includes Januvia® 100 mg daily. The physician has ordered a fasting blood sugar (FBS), electrolytes, and a CBC. You will need to collect a venipuncture blood specimen to send the lab. During the exam Sylvia states she is feeling light-headed, so the licensed practitioner asks you to perform a waived blood sugar and hemoglobin A1C immediately.

Keep Sylvia in mind as you study this chapter. There will be questions at the end of the chapter based on the case study. The information in the chapter will help you answer these questions.

ACTIVSim

LEARNING OUTCOMES

After completing Chapter 48, you will be able to:

- 48.1** Discuss the role of the medical assistant when collecting, processing, and testing blood specimens.
- 48.2** Describe the equipment needed to collect a blood specimen.
- 48.3** Summarize ways to communicate with patients and to respond to their needs when collecting blood.
- 48.4** Carry out the procedure for collecting a blood specimen.
- 48.5** Carry out the procedure for performing blood tests.

- I.C.10** Identify CLIA waived tests associated with common diseases
- I.C.12** Identify quality assurance practices in healthcare
- I.P.2.** Perform:
 - (b) venipuncture
 - (c) capillary puncture
- I.P.8** Instruct and prepare a patient for a procedure or a treatment
- I.P.10** Perform a quality control measure
- I.P.11** Obtain specimens and perform:
 - (a) CLIA waived hematology
 - (b) CLIA waived chemistry test
 - (d) CLIA waived immunology test
- I.A.3** Show awareness of a patient's concerns related to the procedure being performed
- II.P.2** Differentiate between normal and abnormal test results
- II.P.3** Maintain laboratory test results using flow sheets
- II.A.1** Reassure a patient of the accuracy of the test results
- III.P.2** Select appropriate barrier/personal protective equipment (PPE)
- III.A.1** Recognize the implications for failure to comply with Centers for Disease Control (CDC) regulations in healthcare settings
- X.P.3** Document patient care accurately in the medical record

3. Medical Terminology

- d. Define and use acceptable medical abbreviations when appropriate and acceptable

9. Medical Office Clinical Procedures

- a. Practice standard precautions and perform disinfection/sterilization techniques
- j. Make adaptations with patients with special needs

10. Medical Laboratory Procedures

- a. Practice quality control
- b. Perform selected CLIA-waived tests that assist with diagnosis and treatment
 - (2) Hematology testing
 - (3) Chemistry testing
 - (4) Immunology testing
- c. Dispose of biohazardous materials
- d. Collect, label, and process specimens
 - (1) Perform venipuncture
 - (2) Perform capillary puncture

► Introduction

In many healthcare settings, the medical assistant is responsible for collecting blood specimens from patients and sometimes performing waived testing. In this chapter, you will be introduced to venipuncture and capillary collection procedures and you will learn the appropriate supplies and equipment needed to perform these procedures. You also will learn techniques for dealing with different types of patients and how to obtain blood specimens efficiently and effectively. Additionally, you will receive instruction on the performance and screening of common blood tests.

► The Role of the Medical Assistant LO 48.1

The examination of blood can provide extensive information about a patient's condition. You may be asked to collect and process blood specimens for examination in your work as a medical assistant. A basic understanding of the anatomy and physiology of the circulatory system will help you properly perform these tasks. You also will need a working knowledge of the functions of blood and the kinds of cells that make up blood tissue. (See the chapters *The Cardiovascular System* and *The Blood* for more information.)

You will use several techniques to obtain blood specimens. **Phlebotomy** is the withdrawal of blood from a vein. This is done using a procedure called **venipuncture**: the puncture of a vein with a needle for the purpose of drawing blood. Phlebotomists receive special training in phlebotomy; drawing blood is the main task in their work. Smaller blood specimens may be obtained by using a small, disposable instrument to pierce the surface of the skin and collect blood from the capillaries there. This is known as **capillary puncture**. It is sometimes referred to as *dermal puncture*, since the puncture is made through the dermis of the skin. You must be able to perform such procedures accurately so that the specimen is appropriate for the ordered tests. You also must be skilled in putting the patient at ease during this procedure. Your reassuring manner, ability to handle technical problems, and careful preparation for answering many kinds of questions will be important to your success in this area.

In addition to your many duties as a medical assistant, you must understand how to process blood specimens and conduct various blood tests, particularly if you work in a laboratory. You also must be able to complete the necessary paperwork to ensure that test results are handled efficiently and accurately. All these skills are essential, regardless of whether you collect blood specimens in a physician's office laboratory (POL), hospital, or laboratory drawing station.

► Preparation for Collecting Blood Specimens

LO 48.2

Following the steps in the standard process for drawing blood specimens will enable you to perform the procedure smoothly, accurately, and safely while ensuring properly completed documentation.

Reading and Interpreting the Test Order

The first steps in preparing to draw blood for testing are to review the written testing request and to assemble the equipment and supplies. The patient should arrive with a laboratory **requisition** form and/or the patient's EHR will reflect the licensed practitioner's order for the laboratory tests.

Your first step is to review this blood-collection order to determine what tests will be run. See Figure 48-1. Many tests require expedited or special handling to ensure accurate results.

Your office will have specific collection procedures for each type of test. If you will be sending the blood specimen to a reference laboratory for testing, make sure you know its requirements. The cost of reprocessing a test far surpasses the extra time needed to be sure of the process requirements.

When reviewing the test order, you will need to know the meaning of abbreviations in order to understand the requisition and to collect the correct amount of blood using the correct technique. See Table 48-1. If you are ever in doubt and the resources in your facility do not provide the answers, you should ask your supervisor or supervising practitioner.

Equipment for Drawing Blood

Specific blood-drawing equipment and collection devices vary with the type of test. Make sure you have the appropriate equipment to collect all necessary specimens if more than one test is ordered. All specimen-collection tubes, slides, and other containers should be labeled immediately after collection with the patient's name, the date and time of collection, the initials of the person collecting the specimen, and other information as required by the test procedure or your office (see Figure 48-2a). Some offices use an identification code for each patient.

Alcohol wipes, sterile gauze, and adhesive bandages are standard supplies for procedures during which blood is drawn from a vein or capillaries. However, alcohol can cause inaccurate results for certain tests, so for these tests, povidone-iodine or benzalkonium chloride may be used to clean the puncture site. You will need a **tourniquet** (a flat, broad length of vinyl or rubber or a piece of fabric with a Velcro® closure) for venipuncture (see Figure 48-2b).

All blood collection requires the use of a needle or other sharps device. Recall from the chapter *Infection Control Practices* that you must follow safe injection practices and use safety-engineered devices. In addition, personal protective equipment (PPE) must be used. See the *Caution: Handle with Care* feature Phlebotomy and Personal Protective Equipment.

Go to CONNECT to see a video exercise about *Quality Control Procedures for Blood Specimen Collection*.

Venipuncture requires puncturing a vein with a needle and collecting blood into either a tube or in some cases a syringe. Capillary puncture requires a superficial puncture of the skin with a sharp point. Capillary puncture releases a smaller amount of blood.

Various instruments are used to perform venipuncture and capillary puncture. See Figure 48-3. Be familiar with and practice using the devices so that your technique is smooth, steady, and competent.

Evacuated Systems Evacuated systems—the most common is the Vacutainer® system (manufactured by Becton Dickinson)—use a double-pointed needle, a plastic needle holder/adaptor, and collection tubes (Figure 48-4). The collection tubes are sealed to create a slight vacuum and are called evacuated tubes. You insert the covered inner point of the needle into one end of the holder/adaptor and the first collection tube into the other end.

An evacuated system has several advantages over other methods of blood collection. It is easy to collect several specimens from one venipuncture site using the interchangeable collection tubes, which are calibrated by vacuum to collect the exact amount of blood required. Some collection tubes are prepared with additives needed to correctly process the blood specimen for testing, such as anticoagulants. Finally, because there is no need to transfer blood from a collection syringe to a specimen tube, the potential for exposure to contaminated blood is reduced.

Butterfly Systems You may use a **butterfly system**, or winged infusion set, when you work with patients who have small or fragile veins. Flexible wings attached to the needle simplify needle insertion. A length of flexible tubing (either 5 or 12 inches, approximately) connects the needle to the collection device. The inserted needle remains completely undisturbed while the collection device is manipulated. Because it is motionless, the needle causes less trauma to the vein and surrounding tissue than other venipuncture systems. A butterfly system also generally uses a smaller needle (23-gauge) than other venipuncture techniques and can be used with an evacuated collection tube or a syringe (Figure 48-5).

Needle and Syringe Systems When a patient has small or fragile veins, the vacuum created when the collection tube is pressed over the needle point can cause the veins to collapse. Although it is the least desirable method of collection, you may need to collect blood using a sterile needle and syringe assembly when an evacuated system is not suitable, such as when the patient is difficult to stick. You can use a smaller needle—no smaller than 23-gauge to

TABLE 48-1 Abbreviations Routinely Used in Blood Tests			
Abbreviation	Meaning	Abbreviation	Meaning
Ab	Antibody	BT	Bleeding time
ABO	Classification system for four blood groups	BUN	Blood urea nitrogen
AcAc	Acetoacetate	Ca; Ca ⁺⁺	Calcium
ACE	Angiotensin-converting enzyme	CA	Cancer antigen
ACT	Activated coagulation time	CBC	Complete blood (cell) count
ACTH	Adrenocorticotrophic hormone	CEA	Carcinoembryonic antigen
ADH	Antidiuretic hormone	CHS	Cholinesterase test
AFB	Acid-fast bacillus	CMV	Cytomegalovirus
AFP	Alpha-fetoprotein	CO	Carbon monoxide
Ag	Antigen	CO ₂	Carbon dioxide
AG	Anion gap	COHb	Carboxyhemoglobin
A/G R	Albumin-globulin ratio	CPK	Creatine phosphokinase
ALB	Albumin	CRCL	Creatinine clearance
ALP; alk phos	Alkaline phosphatase	Cre	Creatinine
ALT	Alanine aminotransferase	DHEA-SO ₄	Dehydroepiandrosterone sulfate
ANA	Antinuclear antibody	Dif, Diff	Differential (blood cell count)
APAP	Acetaminophen	EBNA-IgG	Epstein-Barr virus nuclear antigen
APTT	Activated partial thromboplastin time	EBV	Epstein-Barr virus
ASA	Acetylsalicylic acid (aspirin)	EDTA	Ethylenediaminetetraacetic acid
AST	Aspartate aminotransferase	ELP	Electrophoresis, protein
AT-III	Antithrombin III	Eos	Eosinophil
B	Blood (whole blood)	Eq	Equivalent
Baso	Basophil	ESR	Erythrocyte sedimentation rate
BCA; BRCA	Breast cancer antigen	ETOH	Alcohol
BJP	Bence Jones protein	FBS	Fasting blood sugar

(continued)

TABLE 48-1

Abbreviation	Meaning	Abbreviation	Meaning
Free T ₄	Free thyroxine	MPV	Mean platelet volume
FSH	Follicle-stimulating hormone (follitropin)	msAFP	Maternal serum alpha-fetoprotein
FTI	Free thyroxine index	NE	Norepinephrine
GFR	Glomerular filtration rate	OGTT	Oral glucose tolerance test
GH	Growth hormone	P	Plasma
GHRH	Growth hormone-releasing hormone	PBG	Porphobilinogen
GnRH	Gonadotropin-releasing hormone	PCT	Prothrombin consumption time
GTT	Glucose tolerance test	PCV	Packed cell volume (hematocrit)
HA	Hemagglutination	Pi	Inorganic phosphate
HA1C, HgbA1c	Glycosylated hemoglobin	PKU	Phenylketonuria
HAI	Hemagglutination inhibition test	PLT	Platelet
HAV	Hepatitis A virus	PMN	Polymorphonuclear (leukocyte; neutrophil)
Hb; Hgb	Hemoglobin	PRL	Prolactin
HbCO	Carboxyhemoglobin	PSA	Prostate-specific antigen
HBV	Hepatitis B virus	PT	Prothrombin time
HCG; hCG	Human chorionic gonadotropin	PTH	Parathyroid hormone
Hct	Hematocrit	PTT	Partial thromboplastin time
HCV	Hepatitis C virus	PZP	Pregnancy zone protein
HDL	High-density lipoprotein	RAIU	Thyroid uptake of radioactive iodine
HDV	Hepatitis delta virus	RBC	Red blood cell; red blood (cell) count
HGH; hGH	Human growth hormone	RBP	Retinol-binding protein
HIV	Human immunodeficiency virus	RDW	Red cell distribution of width
HLA	Human leukocyte antigen	Retic	Reticulocyte
HPV	Human papillomavirus	RF	Rheumatoid factor; relative fluorescence unit
HSV	Herpes simplex virus	Rh	Rhesus factor
HTLV	Human T-cell lymphotropic virus	RIA	Radioimmunoassay
Ig	Immunoglobulin	rT ₃ or REVT ₃	Reverse triiodothyronine
IgE	Immunoglobulin E	S	Serum
INH	Inhibitor	Segs	Segmented polymorphonuclear leukocyte
IV	Intravenous	SPE	Serum protein electrophoresis
L	Liver	T ₃	Triiodothyronine
LD; LDH	Lactate dehydrogenase	T ₄	Thyroxine
LDL	Low-density lipoprotein	TBG	Thyroxine-binding globulin
LH	Luteinizing hormone	TBV	Total blood volume
LMWH	Low-molecular-weight heparin	TG	Triglyceride
Lytes	Electrolytes	TRH	Thyrotropin-releasing hormone
MCH	Mean corpuscular hemoglobin	TSH	Thyroid-stimulating hormone
MCHC	Mean corpuscular hemoglobin concentration	VDRL	Venereal Disease Research Laboratory (test for syphilis)
MCV	Mean corpuscular volume	VLDL	Very low-density lipoprotein
MHb	Methemoglobin	WB	Western blot
MONO	Monocyte	WBC	White blood cell; white blood (cell) count

(a) Specimen collection tubes must be labeled with all required information immediately after collection.

(b) Common blood collection equipment.

FIGURE 48-2 A variety of equipment is needed to perform routine blood collection.

© McGraw-Hill Education. Sandra Mesrine, photographer

FIGURE 48-4 The Vacutainer® system uses interchangeable collection tubes that allow you to draw several blood specimens from the same venipuncture site.

avoid hemolyzing the blood—and control the vacuum in the syringe by pulling the plunger back slowly. Other aspects of the procedure are essentially the same, except that the blood specimen is collected in the syringe and must immediately be transferred to a collection tube.

Collection Tubes No matter which method is used to collect blood, the specimens must immediately be mixed with the appropriate additives in the correct collection tubes before they are transported to the laboratory for testing. The tube stoppers are different colors, each color identifying the type of additives (if any) a collection tube contains (Figure 48-6).

FIGURE 48-3 Various venipuncture and capillary puncture safety devices.

© Leesa Whicker

FIGURE 48-5 Once inserted, the needle of a butterfly system remains undisturbed during specimen collection.

These additives must be compatible with the laboratory process the specimen will undergo. Each laboratory may choose which tubes to use for a particular test.

FIGURE 48-6 Special color-coded stoppers on collection tubes indicate which additives are present and, therefore, which types of laboratory tests may be performed on each blood specimen.

© Lillian Mundt

Additives include anticoagulants, such as **ethylenediamine-tetraacetic acid (EDTA)**, and other materials that help preserve or process a specimen for particular types of testing. When you collect a blood specimen, double-check that you are using the appropriate collection tubes for the tests ordered. You also must fill the tubes in a specific order to preserve the integrity of each blood specimen by preventing carryover of tube additives from one tube to the next. Each laboratory requires a specific order of draw for collection tubes. The National Committee for Clinical Laboratory Standards also publishes its recommended order of draw. Table 48-2 identifies collection tube stopper colors, additives present in the tubes, and types of tests, in a typical order of draw.

Capillary Puncture Blood from a capillary puncture may be collected in small, calibrated glass tubes; collected on glass microscope slides; or applied directly to reagent strips (or dipsticks), which are specially treated paper or plastic strips used

Stopper Color	Additive	Test Types
Yellow 	Sodium polyanetholsulfonate	Blood cultures
Light blue 	Sodium citrate	Coagulation studies
Red 	None	Blood chemistries, HIV/AIDS antibody, viral studies, and serologic tests
Gold or red/gray 	Clot activator Silicone serum separator	Tests requiring blood serum, routine blood donor screening, and infectious disease testing
Green 	Heparin	Electrolyte studies and arterial blood gases
Lavender 	Ethylenediaminetetraacetic acid (EDTA) (anticoagulant)	Hematology and blood chemistries
Gray 	Potassium oxalate or sodium fluoride (anticoagulant)	Blood glucose

Note: Tubes are listed in the order they should be collected (order of draw).

in specific diagnostic tests. Blood also may be collected on special cards or paper and sent to an outside laboratory for special screening tests such as PKU. PKU testing is discussed in the *Assisting in Pediatrics* chapter.

Lancets Lancets are used in the capillary puncture technique. This technique is employed when the amount of blood required for a specific procedure is not very large or when technical difficulties prevent the use of the venipuncture technique. A **lancet** is a small, disposable instrument with a sharp point used to puncture the skin and make a shallow incision (between 2.0 and 3.0 mm deep for an adult and no deeper than 2.4 mm for an infant). The blood welling up from the incision is then collected.

Automatic Puncturing Devices Automatic puncturing devices are loaded with a lancet. Because the depth to which they puncture the skin is mechanically controlled, they are more accurate and comfortable than the traditional lancet method. These spring-loaded devices have disposable platforms that rest on the finger. Different platforms are used, depending on the desired depth of the puncture. Both the lancet and the platform should be discarded after use. Pen-like devices also can hold a lancet inside. This device is held against the skin and activated by pushing a button. The advantages of these devices are that they are easy to use, the puncture depth can be easily adjusted, and there is an automatic ejection button for lancet disposal. Some companies also manufacture completely disposable devices, which come individually wrapped and are used only once.

Micropipettes A pipette is a calibrated glass tube for measuring fluids. A **micropipette** is a small pipette that holds a small, precise volume of fluid. You will use micropipettes to collect capillary blood for some tests. Capillary tubes, with a single calibration mark, are also used to collect capillary blood for certain tests.

Microtainer® Tubes Microtainer® tubes (manufactured by Becton Dickinson Vacutainer® Systems) are small plastic tubes with a wide-mouthed collector, similar to a funnel, that allows blood to flow quickly and freely into the tube. Like collection tubes in an evacuated system, Microtainer® tubes have different colored tops indicating the additives, if any, they contain.

Reagent Products Several common tests do not require processing of blood specimens. For these tests, you may apply droplets of freshly collected blood to chemically treated paper or plastic reagent strips (dipsticks) or add freshly collected blood droplets to small containers holding chemicals that react in the presence of specific substances or microorganisms. Some of the blood tests performed in this way detect blood glucose levels, sickle cell anemia, infectious mononucleosis, and rheumatoid arthritis.

Smear Slides You may need to apply a drop of freshly collected blood to a prepared microscope slide for some tests. More commonly, a smear slide is prepared in the laboratory

from a blood specimen containing an anticoagulant, for examination under a microscope.

► Patient Preparation and Communication

LO 48.3

After you review the test order and assemble the necessary equipment and supplies, take a moment to relax, gather your thoughts, and consider the patient and your purpose. You need to greet the patient and explain the procedure, as well as ensure patient compliance. In addition, the patient may be anxious about the blood test, and some patients have special needs or present special problems that make drawing blood challenging. Being aware of possible sources of patient anxiety and understanding a wide range of special concerns can help you respond to patient needs with sensitivity and competence.

Greeting and Identifying Patients

Greet patients pleasantly, introduce yourself, and explain that you will be drawing some blood. It is essential to identify patients correctly before you begin the procedure. Ask patients to state their full name and be sure you hear both the first and last names correctly. Verify that the name the patient gives is the name on the order. In most facilities, the phlebotomist should ask for a date of birth and verify the patient ID or chart number against the order to further identify the patient as mandated by The Joint Commission (TJC).

Confirming Pretest Preparation

The presence and level of certain substances in blood are affected by food and fluid intake or by other daily life activities. Some tests require the patient to follow certain pretest restrictions to minimize the influence of the restricted food on the blood, or to stress the body to see how it responds, as indicated by the blood.

Fasting is the most common requirement for pretest preparation. For example, a lipid profile, which measures cholesterol, triglycerides, HDL, LDL, and VLDL, requires fasting. A fasting blood sugar (FBS) requires fasting, as do other types of glucose testing. For example, the glucose tolerance test measures a patient's ability to metabolize carbohydrates and is used to detect hypoglycemia and diabetes mellitus. The patient must eat a high-carbohydrate diet for 3 days before the test and fast for 8 to 12 hours before the appointment.

Before you draw blood for any test, determine whether the patient has complied with pretest instructions. If the patient has not complied, explain that the test cannot be performed. Make a note on the order and report the information to the licensed practitioner or your supervisor.

Explaining the Procedure and Safety Precautions

Explain to the patient the procedure you will use to obtain the blood specimen for testing. Be clear and brief when you describe what you will do; too much detail leaves some

patients queasy. Explain the need for each of the preventive measures, such as the use of PPE, in language the patient can understand. Assure the patient that these measures protect against exposure to infection.

Establishing a Chain of Custody

You will need to follow specific guidelines to establish a chain of custody for blood specimens drawn for drug and alcohol analysis. Because donating a specimen for drug and alcohol testing is potentially self-incriminating, the patient must sign a consent form for the testing. The *Collecting, Processing, and Testing Urine and Stool Specimens* chapter explains general chain-of-custody procedures.

Patient Fears and Concerns

Some patients express their fears or concerns directly. Other patients ask questions that highlight their fears. Providing more information or a complete understanding is reassuring to many patients. For others, the information serves only to confuse, overwhelm, or create more fear. You must decide how much information to give each patient and be prepared to answer questions.

Patients sometimes ask questions that are not appropriate for you to answer. A patient may ask you about his prognosis, medical condition, blood type, or other medical information. It is not appropriate for you to discuss these topics with the

patient. Encourage the patient to discuss these issues with the licensed practitioner. Some commonly expressed fears and concerns to which you should respond, however, are covered in the following paragraphs.

Pain The question medical assistants performing phlebotomy probably hear most often is “Will this hurt”? Never lie to a patient who asks this question. Inform the patient that he will feel a stick just as the lancet or point of the needle is inserted but that this pain goes away almost immediately. Tell a patient who seems particularly nervous to take a deep breath and let it out slowly. Also suggest that the patient focus on something else in the room or close his eyes and relax during the procedure.

A patient may express concern and report a previous unpleasant experience with blood testing. Listen to the patient’s concerns. Describe what you will do to reduce discomfort and what the patient can do to be more at ease. Let the patient know you will help him sit comfortably or lie down while the blood specimen is being obtained. Tell the patient to let you know if he begins to feel light-headed. You might also ask the patient whether one arm is better to use than the other. Many patients have had blood drawn before and can tell you which sites were successful. Consulting the patient helps the patient feel more in control and provides you with important information.

CAUTION: HANDLE WITH CARE

Phlebotomy and Personal Protective Equipment

The Centers for Disease Control and Prevention (CDC) has classified all phlebotomy procedures as a risk for exposure to contaminated blood or blood products. You must use appropriate personal protective equipment (PPE) during all phlebotomy procedures. Remember, it is up to you to protect yourself and the patient.

Gloves

Gloves—which protect against spills and splashing of contaminated blood—are the first line of defense during a phlebotomy procedure. Wash your hands and don clean exam gloves that fit snugly before you work with each patient. Remove the gloves, dispose of them in a biohazardous waste container, and wash your hands after working with each patient.

Garments

Garments such as laboratory coats and aprons can protect your clothing from spills and splashes and provide a measure of protection from contaminated materials. Some garments are designed to resist penetration by blood or blood products. You may find it necessary to wear such garments when drawing blood or performing blood tests.

Masks and Protective Eyewear

Mucous membranes are especially vulnerable to invasion by infectious agents. Use masks and protective eyewear to help safeguard mucous membranes in your mouth, nose, and eyes from infection.

Masks help protect your mouth and nose from splashes or sprays of blood or blood products. You cannot predict when exposure to blood may occur. Accidental puncture of an artery during a phlebotomy procedure could result in a spray of blood, or blood may spray or splash accidentally during testing protocols. Most medical assistants do not routinely wear masks for phlebotomy procedures once they have achieved proficiency in performing them. Goggles can also protect your eyes from splashing and spraying during blood drawing or testing.

Clear plastic face shields combine the protection of masks and goggles and are often used during major surgical procedures. You may use a face shield if you do extensive testing on blood specimens, but face shields are not usually worn when drawing blood.

PPE works two ways: It protects you from a patient’s contaminated blood and it protects the patient from infectious agents you may be carrying. By using PPE correctly, you will make your workplace a safer place for you and the patients.

Scars Some patients may express fear of getting a bruise or scar from a blood collection procedure. Explain that some bruising is possible but that it will fade within a few days. Most bruising is caused by a hematoma, which occurs when blood leaks out of the vein and collects under the skin. Hematomas can be prevented by releasing the tourniquet before withdrawing the needle and applying proper pressure over the puncture site after the needle has been withdrawn. Bruising is common with fair-skinned patients. Scars, on the other hand, are unlikely.

Serious Diagnosis Patient fears are not always rational. One fear patients express is that the more tubes of blood you require, the more serious their condition must be. Patients also may fear that a blood test is being done to help the practitioner diagnose an extremely serious disease.

You can help relieve a patient's fears by explaining that a blood test is one of the best ways to obtain an overall picture of health (emphasize health, not disease). Note that blood tests show what is normal about the blood as well as any abnormalities. You might also explain that several specimens are being taken because the blood used in blood tests is processed in different ways; the blood collected for one test cannot be used in another.

Blood testing also may be done to determine how well and at what levels medications are acting in the blood. Explain that the practitioner may want to see how much medication is in the blood to better manage the prescribed dosage. When a patient needs repeated tests for drug levels, explain that the tests show how the body is using the medication.

Contracting a Disease from the Procedure Probably the greatest fear of patients undergoing blood tests is contracting HIV/AIDS or hepatitis B virus (HBV). Although many people are now well informed about how HIV/AIDS and other serious diseases are contracted, it is understandable for a patient to worry about bloodborne pathogens. Do not dismiss the patient's concerns and do not downplay the importance of following standard precautions.

Explain the precautions you will take to prevent the spread of infection. Allow the patient to see you wash your hands and put on new gloves before you begin to take the blood specimen. Stress that the needle is sterile. Explain that you have not touched the needle and that it will be discarded when you finish. Let the patient see you put the needle in the sharps container.

Use this opportunity to educate the patient about the transmission of HIV/AIDS. Emphasize that HIV/AIDS, and other infections transmitted by blood, can be transmitted only when there is direct contact with contaminated blood or other body fluids. Explain that your gloves protect both you and the patient by providing a barrier to infection transmission from one person to another. Explain that your other protective equipment, such as goggles or a mask, also helps prevent the spread of infection.

Special Considerations

As you collect blood specimens, you will encounter a variety of patients, some of whom have special needs. You will find yourself in many different situations, some of them

problematic. Some special needs and problematic situations are fairly common, and you must be prepared to deal with them.

Patients at Risk for Uncontrolled Bleeding Patients who have hemophilia or are taking blood-thinning medications are at risk for uncontrolled bleeding at the collection site. (Hemophilia is a disorder in which the blood does not coagulate at a wound or puncture site.) Be especially careful and alert as you follow the standard procedures for collecting a blood specimen. In addition, hold several gauze squares over the puncture site for at least 5 minutes to make sure bleeding has stopped completely. If uncontrolled bleeding does occur, call the licensed practitioner immediately.

Difficult Patients You may encounter a particular challenge in working with a patient either because of technical problems or because of personality issues. Being prepared for these situations is the best method for coping with them.

The Difficult Venipuncture There will be times when you simply cannot get a good blood specimen. If your first attempt at drawing blood fails, try again at another site. Give the patient (and yourself) a short break and make an attempt on the other arm, for instance. Sometimes the veins in one arm are easier to work with than the veins in the other arm. Some facilities may have available an instrument, such as a **venoscope**, to visualize the vein. The battery-operated venoscope uses light-emitting diode (LED) lights to illuminate the subcutaneous tissue and highlight the veins, making the veins easier to locate. If you cannot get a good specimen on the second try, stop. Ask for assistance from your supervisor or the licensed practitioner.

Fainting Patients It is impossible to predict which patients will have a reaction to a blood-drawing procedure. Generally, however, an ill patient is more likely to experience a reaction than a well patient. The best way to deal with this potential problem is to position every patient so that, if fainting does occur, no injury will result. Have patients sit in a special venipuncture chair (Figure 48-7), designed to help prevent patients from sliding to the floor in the event of fainting. If your office is not equipped with a venipuncture chair, have patients lie down on an examining table. A patient who has a history of fainting or feels ill should lie down with feet elevated or knees drawn up while you complete the procedure. Sometimes just talking with the patient, asking her simple questions, will help keep her from fainting.

If a patient does faint and the needle is still in the vein, release the tourniquet and withdraw the needle quickly and steadily. Apply pressure to the site. Most people revive promptly and no other action is required. Do not leave the patient alone. Notify the licensed practitioner that the patient has fainted and ask the practitioner whether you should continue with the procedure.

If there is a more severe reaction, notify the appropriate staff member and remain with the patient. If the patient is in a chair and begins to slide out, raise the safety arm and gently

FIGURE 48-7 Venipuncture chairs are designed to make blood drawing easier and to prevent patients from falling if they should faint.
© Leesa Whicker

lower the patient to the floor. Protect the patient's head at all times and make sure the patient is breathing. The licensed practitioner should examine the patient before the patient is moved. Follow the practitioner's instructions.

When the patient begins to recover, assist the patient into a sitting position and then to a chair or couch. The patient should rest until feeling strong enough to walk—usually about 15 minutes. When the patient feels steady, take the patient to another area of the office, such as the patient reception area. At this point, another staff member usually becomes responsible for the patient's care and determines when it is safe for the patient to leave.

Angry or Violent Patients Some patients are extremely resistant to having blood drawn. Although their objections may seem illogical, remember, people often do not think as clearly in moments of high emotion as they normally do.

Encourage a patient who is mildly upset and wants to argue about the need for the blood test to let you take the specimen and then discuss the situation with the licensed practitioner. If you convince the patient to submit to the test, complete the procedure quickly and accurately. Avoid arguing with the patient.

Do not force the issue with a patient who becomes violent or refuses outright to submit to the procedure. A patient does have the right to refuse testing or treatment. Under no circumstances should you attempt to physically force a patient to give a blood specimen. Never endanger yourself, other patients, or your colleagues by refusing to back down from an angry or violent patient. Report the problem to the appropriate staff, make a note on the order, and follow other established procedures as determined by your facility.

▶ Performing Blood Collection LO 48.4

Venipuncture

Some states permit medical assistants to obtain blood specimens. Your office will clarify which phlebotomy-related duties, if any, you may perform. If your duties include

collecting blood specimens, you will obtain them through either venipuncture or capillary puncture. You must understand when these techniques are used and know how to perform them. Procedure 48-1, at the end of this chapter, details quality control procedures for collecting blood specimens.

The most common sites for venipuncture are the median cubital and cephalic veins of the forearm. Other sites may be used if a primary site is unavailable. Figure 48-8 shows the veins in the antecubital fossa (the small depression inside the bend of the elbow) and the forearm.

In order to locate the correct site and perform the venipuncture, you will need to apply a tourniquet. The tourniquet is applied to the arm 3 to 4 inches above the venipuncture site. Follow the steps shown in Figure 48-9 for proper application of the tourniquet. Procedure 48-2, at the end of this chapter, provides step-by-step instructions for performing the venipuncture using an evacuated system.

Capillary Puncture

Capillary puncture requires a superficial puncture of the skin with either a lancet or an automatic puncture device. Capillary puncture in adults and children is usually performed on the great (middle) finger or the ring finger. Use the patient's nondominant hand for this procedure if possible. The puncture should be made slightly off-center on the pad of the fingertip, because the pad's center is usually more sensitive. Capillary puncture in infants is usually performed on one of the outer edges of the underside of the heel (Figure 48-10). An alternate site for both children and adults is the lower part of the earlobe, unless the patient's ear is pierced. Procedure 48-3, at the end of this chapter, explains how to perform a capillary puncture and collect a sample of capillary blood.

FIGURE 48-8 Veins commonly used for venipuncture include the cephalic vein, the basilic vein, and the median cubital vein.

(a) Position the tourniquet under the arm while grasping the ends above the arm and venipuncture area. The tourniquet should be 3 to 4 inches above the site.

(b) Cross the left end over the right end and apply a small amount of tension to the tourniquet.

(c) Using the right middle finger or index finger, tuck the left end under the right end.

(d) A loose end of the tourniquet will be pointing toward the shoulder and the loop will be pointed toward the hand.

FIGURE 48-9 Follow these steps for proper tourniquet application.

Blood Cultures

Blood culture specimens are collected to test for the presence of bacteria in the blood. When collecting blood for a culture, it is important that no skin organisms contaminate the specimen. Skin organisms such as staphylococci and streptococci can cause a false-positive blood culture test result. For this reason, proper aseptic technique is essential. Pay special attention to keeping the collection bottle, syringe, and needle sterile and properly cleansing the skin. If you are drawing additional specimens for other tests, always draw the blood culture first. This eliminates the possibility of contaminating the culture with additives from other tubes. When collecting a blood culture specimen, you should follow these steps:

1. Select the appropriate site for venipuncture.
2. Cleanse the skin with isopropyl alcohol.
3. Cleanse the skin again with an iodine or chlorhexidine solution applied in an outward, circular pattern (cleansing from inside to outside).
4. Allow the iodine solution to air-dry.

5. Remove the plastic top from the collection bottle and wipe with a sterile alcohol pad.
6. Allow the alcohol to air-dry.
7. Draw the blood from the selected site.
8. Properly label the specimens.

Separate blood specimens are put into two collection bottles, one for aerobic and one for anaerobic culture. You may be asked to draw a second set of specimens from another vein. Use the same technique for each specimen, and make sure all specimens are properly identified.

Venipuncture Complications

Venipuncture is, in general, a safe procedure. Most of the complications you encounter are mild and more of a nuisance than anything. Venipuncture can have some serious complications, but they are rare. You must be aware of possible complications and ways to avoid them, and you should understand how to deal with them if they occur. Some of the more serious complications you may encounter are

- **Hematoma.** A collection of blood will sometimes form under the skin. This is especially a problem in patients who

(a)

(b)

FIGURE 48-10 Capillary puncture sites for (a) an adult and (b) an infant.

© Leesa Whicker

have bleeding disorders, are elderly, or are taking anticoagulants. To avoid hematomas, hold the needle as still as possible while filling and changing the tubes. You may need to use a butterfly collection device. Hold pressure on the venipuncture site as soon as you remove the needle. Have the patient elevate her arm but not bend the elbow. If a hematoma does form, apply extra gauze to the puncture site and wrap with stretch bandage. Watch the patient and alert the licensed practitioner if necessary.

- **Latex allergy.** Some patients have an allergy to latex. Make sure you ask the patient if he has any allergies before you begin the procedure. If the patient has a latex allergy, make sure you use nonlatex gloves, tourniquet, and bandages. If the patient has an unexpected allergic reaction to latex, alert the licensed practitioner and follow her instructions.
- **Nerve injury.** It is essential that you know the anatomy of the antecubital fossa so that you can accurately locate the proper veins for venipuncture. Inserting a needle into a nerve can cause nerve damage. Permanent sensory and/or motor damage to the arm and hand can occur if the venipuncture is done incorrectly. If you suspect you have stuck the patient's nerve, withdraw the needle immediately and alert the licensed practitioner.

- **Infections.** Though quite rare, infections after venipuncture do occur and can be very serious. Use only approved single-use venipuncture equipment. Cleanse the venipuncture site well before the procedure. An infection at the venipuncture site may not be evident for several days after the procedure. If the patient calls, complaining of redness, heat, or drainage at the site, have her return to the office to see the licensed practitioner. A more serious blood infection (sepsis) may at first seem like the patient has the flu, as fever and chills are the first symptoms. A patient with a blood infection can go into shock if left untreated. If you suspect that the patient has a blood infection, have her see the licensed practitioner immediately.

▶ Performing Common Blood Tests LO 48.5

Many blood tests are routinely ordered as part of a complete general exam to determine a patient's overall health. The results of individual tests can provide information that aids in the diagnosis of specific conditions, diseases, and disorders, as noted in Table 48-3.

The number of blood tests routinely performed in POLs has declined since the implementation of Clinical Laboratory

TABLE 48-3 Common Blood Tests and the Conditions They Help Identify

Substance Identified or Quantified	Stopper Color and Additive	Part of Blood Tested	Indication, Disease, or Disorder
Alanine aminotransferase (ALT)	 Clot activator  Silicone serum separator	Serum	Liver disorders
Alpha-fetoprotein (AFP)	 Clot activator  Silicone serum separator	Fetal serum	Fetal liver and gastrointestinal tract status, and hepatitis
Amylase	 Clot activator  Silicone serum separator	Serum	Drug toxicity and parotid or pancreas disorders
Angiotensin-converting enzyme (ACE)	 Clot activator  Silicone serum separator	Serum	Lung cancer, sarcoidosis, and acute or chronic bronchitis
Antidiuretic hormone (ADH)	 EDTA	Plasma	Syndrome of inappropriate ADH, Guillain-Barré syndrome, and brain tumor

(continued)

TABLE 48-3 Common Blood Tests and the Conditions They Help Identify

Substance Identified or Quantified	Stopper Color and Additive	Part of Blood Tested	Indication, Disease, or Disorder
Aspartate aminotransferase (AST)	 Clot activator Silicone serum separator	Serum	Liver disease (including viral hepatitis), infectious mononucleosis, and damaged heart or skeletal muscle
Bilirubin	 Clot activator Silicone serum separator	Serum	Liver disease, fructose intolerance, and hypothyroidism
Blood urea nitrogen (BUN)	 Clot activator Silicone serum separator	Serum	Kidney disorders
Calcium, total (fasting)	 Clot activator Silicone serum separator	Serum	Hyperparathyroidism and malignant disease with bone involvement
Cancer antigens (numbers 125, 15-3, 549, 72-4), tumor-associated glycoprotein (TAG)	 Clot activator Silicone serum separator	Serum	Specific cancers identified, depending on antigen tested
Carbon dioxide, total	 Clot activator Silicone serum separator	Venous serum	Acidosis or alkalosis (acid-base balance)
Cholesterol, total	 Clot activator Silicone serum separator	Serum	Hyperlipoproteinemia, coronary artery disease, and atherosclerosis
Creatine kinase (CK)	 Clot activator Silicone serum separator	Serum	Muscular dystrophies, Reye's syndrome, heart disease, shock, and some neoplasms
Erythrocyte count (RBC)	 EDTA	Whole blood	Anemia
Erythrocyte sedimentation rate (ESR)	 EDTA	Whole blood	Inflammation, infectious diseases, malignant neoplasms, and sickle cell anemia
Glucose (fasting)	 Potassium oxalate or sodium fluoride	Whole blood	Pancreatic function and ability of intravenous insulin to offset diet in diabetes mellitus

(continued)

TABLE 48-3 Common Blood Tests and the Conditions They Help Identify

Substance Identified or Quantified	Stopper Color and Additive	Part of Blood Tested	Indication, Disease, or Disorder
Glucose (fasting—tolerance test)	 Potassium oxalate or sodium fluoride	Serum	Diabetes mellitus and hypoglycemia
Lactate dehydrogenase (LD)	 Clot activator Silicone serum separator	Serum	Anemia, viral hepatitis, shock, hypoxia, and hyperthermia
Leukocyte count (WBC)	 EDTA	Whole blood	Leukemia, infection, and leukocytosis
Phenylalanine	 Heparin or newborn screening card	Plasma	Hyperphenylalaninemia, obesity, and phenylketonuria
Potassium (K ⁺) and sodium (Na ⁺)	 Clot activator Silicone serum separator	Serum	Fluid-electrolyte balance
Prostate-specific antigen (PSA)	 Clot activator Silicone serum separator	Serum	Prostate cancer and BPH
Sickle cells	 EDTA	Whole blood	Sickle cell anemia
Thyroid-stimulating hormone (TSH), triiodothyronine (T ₃), thyroxine (T ₄)	 Clot activator Silicone serum separator	Serum	Thyroid function
Uric acid	 Clot activator Silicone serum separator	Serum	Gout and leukemia

Note: Different laboratories may have different testing protocols and may require other tube tops than those represented in this table. Consult your laboratory procedures manual for additional information regarding required collection tubes.

Improvement Amendments of 1988 (CLIA '88) regulations. Many POLs now perform only waived tests. Each POL is different, however, and regulations do change. Check with your employer about what tests your office performs regularly. You should be familiar with a wide range of tests and the steps involved with each, even if you do not anticipate performing them.

Given that some testing can occur in the POL, you may encounter several chemical substances while performing

your responsibilities in the laboratory. Chemicals you might encounter in laboratory work include the following:

- **Anticoagulants**, which cause the blood to remain in a liquid, uncoagulated state
- **Serum separators**, which form a gel-like barrier between serum and the clot in a coagulated blood specimen
- **Stains**, which color specific types of cells, making microscopic studies easier to complete

Anticoagulants or serum separators are already present in blood-collection tubes and do not need to be added to the specimen.

You must be absolutely clear about which chemicals are used for which tests and the precise amounts involved. It is also

important to understand the purpose of blood tests so that you can educate patients. You must, in addition, know the range of normal test values so that you can be aware of potential problems and note them for the licensed practitioner's attention. Table 48-4 shows the normal ranges for a variety of blood tests.

TABLE 48-4 Normal Ranges for Blood Tests

Blood Test	Stopper Color and Additive*		Blood Component Tested	Normal Range**	
Blood Counts					
Red blood cells (erythrocytes) Men Women		EDTA	Whole blood Whole blood	$4.7\text{--}6.1 \times 10^6$ cells/mcL $4.2\text{--}5.4 \times 10^6$ cells/mcL	
White blood cells (leukocytes) Platelets Differential			Whole blood Whole blood Whole blood Whole blood Whole blood Whole blood	$4.5\text{--}11.0 \times 10^3$ cells/mcL $150\text{--}400 \times 10^3$ cells/mcL	
Neutrophils Eosinophils Basophils Lymphocytes Monocytes				40%–60% 1%–4% 0.5%–1% 20%–40% 2%–8%	
Hematocrit (Hct) Men Women	Whole blood	40.7%–50.3% 36.1–44.3%			
Hemoglobin (Hb, Hgb) Men Women	Whole blood	13.8–17.2 g/dL 12.1–15.1 g/dL			
Erythrocyte Sedimentation Rate (ESR)					
Wintrobe Men Women		EDTA		Whole blood	0–5 mm/hour 0–15 mm/hour
Westergren Men Women				Whole blood	0–15 mm/hour 0–20 mm/hour
Coagulation Tests					
Prothrombin time (PT)		Sodium citrate	Plasma	11–15 seconds	
Bleeding time		Sodium citrate	Whole blood	2–7 minutes

*Different laboratories may have different testing protocols and may require other tube tops than those represented in this table. Consult your laboratory procedures manual for additional information regarding required collection tubes.

**Reference ranges for normal values may be slightly different in different labs. Consult the reference ranges provided by your individual lab for each test.

Hematologic Tests

Hematologic tests—including blood cell counts, morphologic studies, coagulation tests, and the nonautomated erythrocyte sedimentation rate test—are commonly performed in routine blood testing. These tests can be performed on venous or capillary whole blood specimens.

Blood Counts Whole blood contains **formed elements** (RBCs, WBCs, and platelets) and a fluid portion (plasma). The total number of blood cells and the percentage of the whole specimen each type represents can tell the licensed practitioner a great deal about a patient's condition. A practitioner can order an individual test or a **complete blood (cell) count (CBC)**, which includes the following tests:

- Red blood (cell) count—the total number of RBCs in a specimen and the red cell morphology
- White blood (cell) count—the total number of WBCs in a specimen
- Differential WBC count—the percentage of each type of WBC (basophils, eosinophils, neutrophils, lymphocytes, and monocytes) in the first 100 leukocytes of a specimen
- Platelet count (automated)—the number of platelets in a specimen, or a platelet estimate, which indicates whether the amount of platelets is adequate
- Hematocrit determination—identifies how much of a specimen's volume (expressed as a percentage) is made up of RBCs after the specimen has spun in a centrifuge
- Hemoglobin determination—measures the amount of hemoglobin by weight per volume in the specimen

Most POLs use automated equipment for performing blood cell counts. Automated equipment performs a differential by counting and classifying all of the WBCs in the sample. You

may need to understand how to perform blood counts manually. All manual counts are estimates. The types of blood cell counts differ in specimen preparation and in the equipment and methods used. Check your state regulations and office policy to find out if you are allowed to perform differential blood counts.

Differential Cell Counts A medical assistant may be trained to prepare a blood smear slide and stain the smear for a manual differential cell count. Procedure 48-4, at the end of this chapter, details preparation of a blood smear slide. When you carry out this process correctly, there will be a region of the slide where blood cells are dense but lie in a single plane (not stacked or bunched together). This is the region where the cells are counted.

A polychromatic (multicolored) stain like Wright's stain simplifies a differential cell count. The blue and red-orange dyes (methylene blue and eosin, respectively) stain cell structures in ways that identify each of the five WBC types. The staining characteristics of each WBC type are

- Neutrophils—dark purple nucleus and pale pink cytoplasm containing fine pink or lavender granules.
- Basophils—purple nucleus and light purple cytoplasm containing large, blue-black granules.
- Eosinophils—purple nucleus and bright orange granules in pink cytoplasm.
- Lymphocytes—large, dark purple nucleus surrounded by a small amount of blue cytoplasm.
- Monocytes—the largest WBC, has gray-blue cytoplasm.

There are several types of blood staining kits. Follow the manufacturer's instructions when performing this procedure.

Figure 48-11 shows the zigzag pattern for counting leukocytes visible in the field when using the microscope's

FIGURE 48-11 Follow this pattern when counting leukocytes visible in the field under the oil-immersion objective of the microscope.

oil-immersion objective. A total of 100 leukocytes are counted and recorded on a differential counter. Each cell type is expressed as a percentage of the 100 leukocytes counted. The platelet count is averaged in 10 to 15 fields.

Hematocrit You measure a patient's hematocrit percentage by collecting a small specimen of the patient's blood in a microhematocrit tube, sealing the tube, and spinning it in a centrifuge. This process is described in Procedure 48-5 at the end of this chapter. During this process, heavier RBCs move to one end of the tube and lighter plasma moves to the other end. Between the RBCs, or **packed red blood cells**, and the plasma is the buffy coat (Figure 48-12). The **buffy coat** contains the WBCs and platelets.

Always run two specimens of the patient's blood. After removing each specimen from the centrifuge, compare the column of packed RBCs with a standard hematocrit gauge. Read on the gauge the percentage of total blood volume represented by the RBCs. The specimens should be within 2% of each other. If they are not, repeat the test. Average the readings of the two patient specimens.

Automated Hematocrit Readers You also may use a handheld device to obtain hematocrit readings. Devices such as the UltraCrit® are CLIA-waived testing devices for rapid and accurate measurement of hematocrit. The test may be completed on venous or capillary blood and results are obtained in less than 1 minute. These devices are often used by blood banks to rapidly screen donors for eligibility to donate.

FIGURE 48-12 Blood in a centrifuged capillary tube separates into packed red blood cells, the buffy coat, and plasma.

Hemoglobin Hemoglobin resides within the RBCs. You will determine the concentration of hemoglobin in the blood by lysing (rupturing) the RBCs (**hemolysis**) and evaluating the color of the specimen. This procedure may be done with a hemoglobinometer—a handheld device that makes color evaluation less subjective (open for interpretation) than older methods of visually matching with color samples. Older testing methods had to be read by the human eye, leaving test interpretation up to the individual eye. Any change in color perception by the person reading the test could affect the test result reading. Blood specimens mixed with a reagent, such as Drabkin's reagent, undergo a color reaction that can be quantified by reading color intensity in a photoelectric colorimeter (an instrument that uses light to read color).

Several automated hemoglobin analyzers are now included on the CLIA '88 waived list. These analyzers measure the amount of hemoglobin in a whole blood sample using a photometer (an instrument used to measure absorbed light). The blood sample can be obtained from either a finger stick or venous blood. Examples of automated hemoglobin analyzers are HemoCue HB 301 Analyzer® (HemoCue AB) and the HemoPoint H2 Hemoglobin Measurement System® (Stanbio Laboratory). Follow the manufacturer's instructions when performing these tests.

Morphologic Studies **Morphology** is the study of the shape or form of objects, which is often performed just after the differential count and platelet estimate on the same blood smear slide. A morphologic study of a blood specimen can provide important information about a patient's condition. It

examines a blood smear specimen and records the appearance and shape of cells for abnormal size, shape, or content and abnormal cell organization. Morphologic studies require special training and are not routinely done by medical assistants.

Coagulation Tests A physician may order coagulation tests to identify potential bleeding problems before surgical procedures or to monitor therapeutic drug levels when a patient is receiving anticoagulant medications such as heparin or warfarin (Coumadin®). Coagulation studies include the prothrombin time (PT) and partial thromboplastin time (PTT) tests. These tests are usually performed using automated devices such as the Coaguchek XS System™ (Roche Diagnostics) or the Alere INRatio System™ (Alere). These systems monitor the changing pattern of light transmission through the specimen as coagulation occurs and calculate the INR (International Normalized Ratio). The INR—used to evaluate patients who are taking blood thinners such as warfarin—measures the amount of time it takes for the test specimen to clot and compares it to a reference average. The World Health Organization (WHO) developed the INR method so that specimens from different labs can be compared. Medical assistants sometimes perform these studies.

Erythrocyte Sedimentation Rate The **erythrocyte sedimentation rate (ESR)** is the rate at which red blood cells (RBCs) settle in whole blood. What is actually measured is the distance, in millimeters, that they fall in 1 hour when allowed to settle in a calibrated tube. The ESR screens for the presence of any inflammatory process and does not diagnose any one condition. When inflammation is present, plasma proteins, such as albumin and globulin, are increased. An increase in these substances causes red blood cells to come closer together, which may result in the red blood cells sticking together. Several cells sticking together settle faster than a single RBC does. This results in an elevated sedimentation rate. See Figure 48-13 and these general guidelines:

- Use only a fresh sample of blood.
- Draw the blood into a tube with anticoagulant additives.
- Temperature, either too hot or too cold, will affect the test. Maintain laboratory temperatures near 70°F.
- Precisely position the specimen tubes vertically in the rack. They must not be leaning.
- Avoid vibrating or bumping the rack during the test.
- Avoid introducing bubbles into the specimen when transferring blood into the tube.
- Carefully watch the time and read the results at exactly 1 hour.

Chemical Tests

Blood chemistry analysis examines several dozen chemicals found in human blood. Tables 48-3 and 48-4 include many of these chemical tests. Highly detailed studies are rarely performed in the POL because they require expensive, sophisticated equipment and techniques. Complex testing is also subject to strict CLIA '88 regulations that increase the administrative work and the need for more highly trained personnel. So these types of tests are commonly performed at an

FIGURE 48-13 Erythrocyte sedimentation rate. (a) An example of one manufacturer's method for Westergren erythrocyte sedimentation rate (Sediplast ESR system). (b) An example of an erythrocyte sedimentation after 1 hour. The reading in this example is 22 millimeters.

independent reference laboratory. Automated equipment for analyzing blood chemistry, however, is becoming more available, less expensive, and simpler to operate than it was in the past. New waived tests for an increasing array of chemicals in the blood are developed each year, making it more likely that you may use automated equipment to perform some blood chemistry tests. Keeping abreast of new developments will help prepare you for possible changes in your laboratory duties.

Blood Glucose Monitoring One of the blood chemistry tests routinely conducted in the POL is blood glucose monitoring, which is often performed by a medical assistant or by a patient. Glucose monitoring systems require sterile lancets to perform a capillary puncture. You will collect the blood on reagent strips that change color in accordance with glucose levels present in the blood. The level is determined either by

comparing the color on the strip with color standards provided with the reagent strips or by feeding the strip into a handheld reading device. You will teach patients to perform this kind of test at home. Be sure to stress the importance of following the manufacturer's guidelines for correct operation. Procedure 48-6, at the end of this chapter, outlines the general steps for measuring blood glucose using a handheld glucometer.

You also will teach patients and their families how to manage diabetes. This will include performing the blood glucose test, managing diet and exercise, and self-monitoring for complications associated with diabetes. You may also provide additional resources for further education. See the *Educating the Patient* feature Managing Diabetes.

Hemoglobin A1C Another test used to monitor the health of diabetic patients is the hemoglobin A1C test. This test measures the amount of glycosylated hemoglobin (hemoglobin with glycosal groups attached) in the blood. When blood glucose levels are elevated, the glucose molecules bind with hemoglobin to form hemoglobin A1C (HgbA1c). Once HgbA1c is formed, it remains for the RBC's life (90 to 120 days). For this reason, the test results provide an idea of the average blood sugar for 2 to 3 months.

Large fluctuations in blood sugar are problematic in patients with diabetes and can cause complications such as

eye disease, stroke, renal failure, and cardiovascular disease. The HgbA1c test gives the physician a good overall picture of the patient's compliance with and the effectiveness of diabetes treatment.

Several options for performing this test include

- Sending it to an outside reference laboratory. Results are available in 1 to 7 days.
- Performing it in the office laboratory if the necessary equipment is available. Results are usually available in less than 10 minutes.
- Taking the test at home. Several home tests are available, allowing patients to monitor their own HgbA1c levels and therefore, the efficiency of their diabetes treatment.

Testing of HgbA1c should always be done in conjunction with routine blood glucose monitoring. Daily monitoring of blood glucose helps the patient with insulin therapy and diet maintenance. HgbA1c monitoring is important in assessing the patient's overall glucose levels. The advantages of this testing include

- No pretesting preparation. The test may be done without regard to meals.
- Better overall assessment of long-term blood glucose control. Blood glucose testing gives information about glucose levels at one point in time. HgbA1c gives information over a period of 2 to 3 months.

Patients should have their HgbA1c levels checked two to four times per year. The target range for HgbA1c levels is less than 7%. Patients whose HgbA1c levels exceed 8% are at a greater risk for diabetes-associated complications.

EDUCATING THE PATIENT

Managing Diabetes

Diabetes affects an estimated 9% of the US population, with more than 1 million newly diagnosed cases each year. In order to reduce the complications associated with diabetes, patients need to maintain stable blood sugar. Proper patient education and medical care will help patients achieve this goal. As a medical assistant, you can assist patients and their families by providing them with the following information about diabetes:

1. The risks and consequences associated with uncontrolled blood sugar. Patients whose blood sugar is unstable are at greater risk of developing the following conditions:
 - Loss of vision
 - Kidney failure
 - Heart disease
 - Nerve damage
 - Stroke
2. The patient's type of diabetes. Patients need to know the type of diabetes they have so that they can understand the type of treatment prescribed. The types of diabetes are
 - Type 1 diabetes—an autoimmune disorder characterized by the body's inability to make enough insulin. Insulin is required for glucose utilization. Patients with Type 1 diabetes will need to take insulin daily.
 - Type 2 diabetes—the most common type of diabetes. Insulin is still being produced at normal levels but can no longer be utilized by the body's cells. This causes a buildup of unused glucose in the blood. This type of diabetes is often controlled with careful diet management and increased exercise. A number of oral medications also can be used.
 - Gestational diabetes—develops only during pregnancy. This type of diabetes is generally managed through proper diet and exercise. Careful monitoring is important to reduce the risk of fetal complications. Women who have had gestational diabetes have an increased risk of developing Type 2 diabetes.
3. Maintaining proper diet and exercise, including
 - Making proper food choices.

- Keeping a food diary.
- Reading food labels.
- Choosing proper food exchanges.
- Creating and implementing a routine exercise program.

4. Routine self-monitoring of blood sugar and hemoglobin A1C levels. Information should include

- The types of blood glucose monitors available. Figure 48-14 illustrates one type—a glucometer.
- Instructions on obtaining monitoring supplies.
- The number of times and the specific intervals at which blood sugar should be checked, based on individual needs and the physician's recommendations.
- Instructions on performing blood glucose testing.
- Guidelines on how to maintain a chart of blood glucose levels, including the time of day, associated meals and activities, and actual blood sugar values.
- Hemoglobin A1C monitoring. The patient should understand what hemoglobin A1C is and why it is important to monitor these values.
- Normal (target) values for blood glucose and hemoglobin A1C:
 - Blood glucose levels should remain between 70 and 130 mg/dL before meals and less than 180 mg/dL for 1 to 2 hours after meals. Target ranges may be different for each patient. Consult with the licensed practitioner about individual blood glucose levels.
 - Hemoglobin A1C is a test that shows the average amount of glucose in the blood over a 3-month period. Ideally, this value should be less than 7%.

5. Symptoms of uncontrolled blood sugar. Patients need to be aware of the symptoms of both high and low blood sugar—both require immediate attention. Patients should test their blood sugar if any of the following occur:

- Nausea, vomiting, or abdominal pain
- Feeling tired all the time
- Excessive thirst or dry mouth
- Flushed skin
- Confusion or difficulty thinking

6. Self-screening for diabetes complications. Patients should be aware of the complications associated with diabetes and how to recognize them, and patients should be instructed to do the following:

FIGURE 48-14 A handheld glucometer is an important tool in helping patients manage diabetes.

© McGraw-Hill Education

- Perform a daily foot inspection for sores
- Recognize changes in vision
- Recognize the symptoms of kidney failure, which include nausea, vomiting, yellow skin, and swelling of the hands and feet
- Recognize early signs of nerve damage, which include numbness and tingling of the arms, hands, feet, or legs; dizziness; double vision; and drooping of the eyelid or lip

7. Additional sources of information. Encourage patients to continue their education about diabetes. Providing patients with additional information encourages them to take an active role in controlling their diabetes. The following are additional information sources:

- American Association of Diabetes Educators 1-800-338-DMED
- American Diabetes Association 1-800-DIABETES
- American Dietetic Association 1-800-366-1665
- Centers for Disease Control and Prevention Diabetes Public Health Resource 1-800-CDC-INFO (232-4636)
- Juvenile Diabetes Research Foundation International 1-800-223-1138
- National Institute of Diabetes and Digestive and Kidney Diseases: National Diabetes Information Clearinghouse 1-800-860-8747

Cholesterol Tests Blood cholesterol tests are performed on a routine basis in the POL. Several automated devices can be used for metabolic chemistry testing both in the POL and at home. These analyzers test a variety of blood chemicals, including glucose, total cholesterol, HDL cholesterol, and triglycerides. The sample required is minimal and can be obtained with a capillary puncture.

FDA-approved waived tests include the following:

- Polymer Technology Systems CardioChek™ Analyzer (Polymer Technology Systems, Inc.)

- SpotChem™ HDL, Total Cholesterol, and Triglyceride (Arkray, Inc.)
- Piccolo® Lipid Panel Plus Reagent Disc (Abaxis, Inc.)

Serologic Tests

Serologic tests detect the presence of specific substances in a blood specimen. The terms *serologic test* and *immunoassay* refer to the introduction of an antigen or antibody into the specimen and the detection of a specific reaction to the antigen or antibody. Serologic testing methods can be used to

detect disease antibodies, drugs, hormones, and vitamins in the blood and to determine blood types. They also are used to test urine and other body fluids.

Immunoassays Although medical assistants usually do not perform immunoassays, you should be familiar with several immunoassay methods that have common applications. These methods include

- Western blot, in which antigens are blotted onto special filter paper for examination. Western blot tests are generally used to confirm HIV infection diagnosis.
- Radioimmunoassay (RIA), in which radioisotopes are used to “tag” antibodies. RIA tests are extremely sensitive and are generally performed in a reference laboratory.
- Enzyme-linked immunosorbent assay (ELISA), in which enzyme-labeled antigens and substances that can absorb antigens generate reactions to specific antibodies. These reactions are identified through visual or photoelectric color detection. HIV infection is diagnosed using an ELISA test.
- Immunofluorescent antibody (IFA) test, in which dye, visible when the specimen is examined under a fluorescent microscope, colors specific antibodies.

Rapid Screening Tests Several serologic tests have been developed for quick processing. Some, such as early pregnancy tests performed on urine, are available for home use. There are also rapid screening tests for detecting antibodies to certain infections:

- Infectious mononucleosis
 - LifeSign Status Mono (Princeton Biomeditech Corp.)
 - BioStar Aceava Mono II (Acon Laboratories, Inc.)
- HIV
 - Clearview HIV—Stat-Pak (Chembio Diagnostic Systems, Inc.)
 - Uni-gold Recombigen HIV Test (Trinity Biotech plc)
- *Helicobacter pylori*
 - Rapid Response *H. pylori* Rapid Test Device (Acon Laboratories, Inc.)
 - Beckman Coulter ICON HP Test (Princeton Biomedtech Corp.)

When you use tests of these types or explain their use to a patient, keep in mind that the manufacturer’s guidelines must be carefully followed to ensure accurate results. Procedure 48-7, at the end of this chapter, outlines the steps for performing a rapid mononucleosis test.

PROCEDURE 48-1 Quality Control Procedures for Blood Specimen Collection **WORK // DOC**

Procedure Goal: To follow proper quality control procedures when collecting a blood specimen

OSHA Guidelines:

Materials: Necessary sterile equipment, specimen-collection container, paperwork related to the type of blood test the specimen is being drawn for, requisition form (chemistry request form), marker, and proper packing materials for transport

Method:

1. Review the request form for the test ordered, verify the procedure, prepare the necessary equipment and paperwork, and prepare the work area.
2. Identify the patient and confirm the patient’s identification. Ask the patient to spell her name. Explain the procedure to be performed and make sure the patient understands it, even if she has had it done before.

3. Confirm that the patient has followed any pretest preparation requirements such as fasting, taking any necessary medication, or stopping a medication. For example, if a fasting specimen is being taken, the patient should not have eaten anything after midnight of the day before. Some practitioners’ offices will let the patient drink water or black coffee, however. It often depends on the type of specimen being taken.

RATIONALE: *The test may be invalid if the patient did not follow the pretest instructions.*

4. Collect the specimen properly. Collect it at the right time intervals if that applies. Use sterile equipment and proper technique.
5. Use the correct specimen-collection containers and the right preservatives, if required. For example, blood collected into a test tube with additives should be mixed immediately.

RATIONALE: *To prevent clotting.*

6. Immediately label the specimens. The label should include the patient name, the date and time of collection, the test name, and the name of the person collecting the specimen. Do not label the containers before collecting the specimen.

RATIONALE: *To keep from wasting tubes if there is a problem drawing the blood.*

7. Follow correct procedures for disposing of hazardous specimen waste and decontaminating the work area.

Used needles, for instance, should immediately be placed in a biohazard sharps container.

8. Thank the patient. Keep the patient in the office if any follow-up observation is necessary.
9. If the specimen is to be transported to an outside laboratory, prepare it for transport in the proper container for that type of specimen, according to OSHA regulations. Place the container in a clear plastic bag with a zip closure and dual pockets with the international biohazard label imprinted in red or orange. The requisition form should be placed in the bag's outside pocket. This ensures protection from contamination

if the specimen leaks. Have a courier pick up the specimen and place it in an appropriate carrier (such as an insulated cooler) with the biohazard label. Place specimens to be sent by mail in appropriate plastic containers, and then place the containers inside a heavy-duty plastic container with a screw-down, nonleaking lid. Then place this container in either a heavy-duty cardboard box or a nylon bag. The words *Human Specimen* or *Body Fluids* should be imprinted on the box or bag. Seal with a strong tape strip.

RATIONALE: To protect the courier and anyone else who handles the package from exposure to bloodborne pathogens.

PROCEDURE 48-2 Performing Venipuncture Using an Evacuated System

WORK // DOC

Procedure Goal: To collect a venous blood specimen using an evacuated system

OSHA Guidelines:

Materials: Patient chart/progress note, requisition form, blood collection components (safety needle, needle holder/adaptor, collection tubes), antiseptic and cotton balls or antiseptic wipes, tourniquet, sterile gauze squares, and sterile adhesive bandages

Method:

1. Review the laboratory requisition form and make sure you have the necessary supplies.
2. Greet the patient, confirm the patient's identity, and introduce yourself.
3. Explain the purpose of the procedure and confirm that the patient has followed the pretest instructions.
RATIONALE: To ensure that the test will be valid.
4. Make sure the patient is sitting in a venipuncture chair or is lying down.
5. Wash your hands. Don exam gloves.
6. Prepare the safety needle holder/adaptor assembly by inserting the threaded side of the needle into the adapter and twisting the adapter in a clockwise direction. Push the first collection tube into the other end of the needle holder/adaptor until the outer edge of the collection tube stopper meets the guideline.

RATIONALE: So that the tube is stabilized but not completely punctured.

7. Ask the patient whether one arm is better than the other for the venipuncture. The chosen arm should be positioned slightly downward.

FIGURE Procedure 48-2 Step 7 The patient's arm should be positioned slightly downward for a venipuncture.

8. Apply the tourniquet to the patient's upper arm midway between the elbow and the shoulder. Wrap the tourniquet around the patient's arm and cross the ends. Holding one end of the tourniquet against the patient's arm, stretch the other end to apply pressure against the patient's skin. Pull a loop of the stretched end under the end held tightly against the patient's skin, as shown in the figure on the next page. The tourniquet should be tight enough to cause the veins to stand out but should not stop the flow of blood. You should still be able to feel the patient's radial pulse.

RATIONALE: To make the veins in the forearm stand out more prominently.

FIGURE Procedure 48-2 Step 8 Applying a tourniquet makes it easier to find a patient's vein when you are drawing blood.

9. Palpate the proposed site and use your index finger to locate the vein, as shown in the figure. The vein will feel like a small tube with some elasticity. If you feel a pulsing beat, you have located an artery. Do not draw blood from an artery. If you cannot locate the vein within 1 minute, release the tourniquet and allow blood to flow freely for 1 to 2 minutes. Then reapply the tourniquet and try again to locate the vein.

FIGURE Procedure 48-2 Step 9 Use your index finger to locate the vein.

10. After locating the vein, clean the area with an antiseptic wipe. Use a circular motion to clean the area, starting at the center and working outward. Allow the site to air-dry.

RATIONALE: *The alcohol could interfere with some of the tests and takes 30 seconds to kill the bacteria.*

11. Remove the plastic cap from the outer point of the needle cover and ask the patient to tighten the fist. Hold the patient's skin taut below the insertion site.

RATIONALE: *To anchor the vein so that it does not roll.*

12. With a steady and quick motion, insert the needle—held at a 15-degree angle, bevel side up, and aligned parallel to the vein—into the vein. You will feel a slight resistance

as the needle tip penetrates the vein wall. Penetrate to a depth of $\frac{1}{4}$ to $\frac{1}{2}$ inch. Grasp the holder/adaptor between your index and great (middle) fingers. Using your thumb, seat the collection tube firmly into place over the needle

FIGURE Procedure 48-2 Step 12 When performing venipuncture, hold the needle at a 15-degree angle.

point, puncturing the rubber stopper. Blood will begin to flow into the collection tube.

13. Fill each tube until the blood stops running to ensure the correct proportion of blood to additives. Switch tubes as needed by pulling one tube out of the adapter and inserting the next in a smooth and steady motion. (The soft plastic cover on the inner point of the needle retracts as each tube is inserted and recovers the needle point as each tube is removed.)
14. Once blood is flowing steadily in the last tube, ask the patient to release the fist and untie the tourniquet by pulling the end of the tucked-in loop. The tourniquet should, in general, be left on no longer than 1 minute.

RATIONALE: *Longer periods may cause hemoconcentration, an increase in the blood-cell-to-plasma ratio, and invalidate test results.*

You must remove the tourniquet before you withdraw the needle from the vein.

RATIONALE: *Removing the tourniquet releases pressure on the vein.*

15. Remove the last tube, then withdraw the needle in a smooth and steady motion, while placing a sterile gauze square over the insertion site. Immediately activate the safety device on the needle if it is not self-activating. Properly dispose of the needle immediately. Instruct the patient to hold the gauze pad in place with slight pressure. The patient should keep the arm straight and slightly elevated for several minutes.

RATIONALE: *To reduce the possibility of a hematoma.*

16. If the collection tubes contain additives, you will need to invert them slowly several times.

RATIONALE: *To mix the chemical agent and the blood specimen.*

17. Label specimens and complete the paperwork.

FIGURE Procedure 48-2 Step 15 Place a sterile gauze square over the insertion site as you withdraw the needle.

18. Check the patient's condition and the puncture site for bleeding. Replace the sterile gauze square with a pressure dressing.
19. Properly dispose of used supplies and disposable instruments and disinfect the work area.
20. Remove the gloves and wash your hands.
21. Instruct the patient about when to remove the pressure dressing.
22. Document the procedure in the patient's chart/progress note.

PROCEDURE 48-3 Performing Capillary Puncture

WORK // DOC

Procedure Goal: To collect a capillary blood specimen using the finger puncture method

OSHA Guidelines:

Materials: Patient chart/progress note, laboratory requisition form, capillary puncture device (safety lancet or automatic puncture device such as an Autolet® or Glucolet®), antiseptic and cotton balls or antiseptic wipes, sterile gauze squares, sterile adhesive bandages, reagent strips, micropipettes, and smear slides

Method:

1. Review the laboratory requisition form and make sure you have the necessary supplies.
2. Greet the patient, confirm the patient's identity, and introduce yourself.
3. Explain the purpose of the procedure and confirm that the patient has followed the pretest instructions, if indicated.
RATIONALE: *The test may be invalid if the patient did not follow the pretest instructions.*
4. Make sure the patient is sitting in the venipuncture chair or is lying down.
5. Wash your hands. Don exam gloves.
6. Examine the patient's hands to determine which finger to use for the procedure. Avoid fingers that are swollen, bruised, scarred, or calloused. Generally, the ring and

great (middle) fingers are the best choices. If you notice that the patient's hands are cold, you may want to warm them between your own, have the patient put them in a warm basin of water or under warm running water, or wrap them in a warm cloth.

RATIONALE: *Warming the patient's hands improves circulation.*

7. Prepare the patient's finger with a gentle "massaging" or rubbing motion toward the fingertip. Keep the patient's hand below heart level so that gravity helps the blood flow.
8. Clean the area with an antiseptic wipe or a cotton ball moistened with antiseptic. Allow the site to air-dry.

RATIONALE: *The alcohol may interfere with some tests.*

9. Hold the patient's finger between your thumb and forefinger. Hold the safety lancet or automatic puncture device at a right angle to the patient's fingerprint, as shown in the figure below. Puncture the skin on the pad

FIGURE Procedure 48-3 Step 9 Hold the lancet or automatic puncture device at a right angle to the patient's fingerprint.

© Leesa Whicker

of the fingertip with a quick, sharp motion. The depth to which you puncture the skin is generally determined by the length of the lancet point. Most automatic puncturing devices are designed to penetrate to the correct depth.

10. Allow a drop of blood to form at the end of the patient's finger. If the blood droplet is slow in forming, apply steady pressure. Avoid milking the patient's finger.

RATIONALE: *It dilutes the blood specimen with tissue fluid and causes hemolysis.*

FIGURE Procedure 48-3 Step 10 Apply steady pressure to the patient's finger, but do not milk it.

© Terry Wild

11. Wipe away the first droplet of blood. (This droplet is usually contaminated with tissue fluids released when the skin is punctured.) Then fill the collection devices, as described.

FIGURE Procedure 48-3 Step 11 Touch the tube to the drop of blood to fill it.

© Leesa Whicker

Micropipettes: Hold the tip of the tube just to the edge of the blood droplet. The tube will fill through capillary action. If you are preparing microhematocrit tubes, you need to seal one end of each tube with clay sealant. (See Procedure 48-5 for this process.)

Reagent strips: With some reagent strips (dipsticks), you must touch the strip to the blood drop but not smear it; with other strips, you must smear it. Follow the manufacturer's guidelines.

Smear slides: Gently touch the blood droplet to the smear slide and process the slide as described in Procedure 48-4.

12. After you have collected the required specimens, dispose of the lancet immediately. Then wipe the patient's finger with a sterile gauze square. Instruct the patient to apply pressure to stop the bleeding.

FIGURE Procedure 48-3 Step 12 Use a sterile gauze square to wipe remaining blood from the patient's finger.

© Terry Wild

13. Label specimens and complete the paperwork. Some tests, such as glucose monitoring, must be completed immediately.
14. Check the puncture site for bleeding. If necessary, replace the sterile gauze square with a sterile adhesive bandage.
15. Properly dispose of used supplies and disposable instruments and disinfect the work area.
16. Remove the gloves and wash your hands.
17. Instruct the patient about care of the puncture site.
18. Document the procedure in the patient's chart/progress note. (If the test has been completed, include the results.)

Procedure Goal: To prepare a blood specimen to be used in a morphologic or other study

OSHA Guidelines:

Materials: Blood specimen (from either a capillary puncture or a specimen tube containing anticoagulated blood), capillary tubes, sterile gauze squares, slide with frosted end, and wooden applicator sticks

Method:

1. Wash your hands and don exam gloves.
2. If using blood from a capillary puncture, follow the steps in Procedure 48-3 to express a drop of blood from the patient's finger. If using a venous specimen, check the specimen for proper labeling, carefully uncap the specimen tube, and use wooden applicator sticks to remove any coagulated blood from the inside rim of the tube. You may use a safety transfer device if available.

RATIONALE: *Uncapping the specimen tube puts you at risk of exposure to bloodborne pathogens. The blood can spray or splatter or the tube could break. The safety device decreases the likelihood of exposure.*

3. Touch the tip of the capillary tube to the blood specimen from either the patient's finger or the specimen tube. The tube will take up the correct amount through capillary action.
4. Pull the capillary tube away from the specimen, holding it carefully to prevent spillage. Wipe the outside of the capillary tube with a sterile gauze square.

RATIONALE: *To remove excess blood.*

5. With the slide on the work surface, hold the capillary tube in one hand and the frosted end of the slide against the work surface with the other.
6. Apply a drop of blood to the slide, about $\frac{3}{4}$ inch from the frosted end, as shown in the figure at the top of the next column. Place the capillary tube in the sharps container.

FIGURE Procedure 48-4 Step 6 Apply a drop of blood to the slide about $\frac{3}{4}$ inch from the frosted end.

7. Pick up the spreader slide with your dominant hand. Hold the slide at approximately a 30- to 35-degree angle. Place the edge of the spreader slide on the smear slide close to the unfrosted end. Pull the spreader slide toward the frosted end until the spreader slide touches the blood drop. Capillary action will spread the droplet along the edge of the spreader slide.

RATIONALE: *So that the specimen can be thinly spread on the slide.*

FIGURE Procedure 48-4 Step 7 Hold the spreader slide at a 30- to 35-degree angle. Pull the spreader slide toward the frosted end until it touches the drop of blood.

8. As soon as the drop spreads out to cover most of the spreader slide edge, push the spreader slide back toward the unfrosted end of the smear slide, pulling the specimen across the slide behind it, as shown in the figure on the next page. Maintain the 30- to 35-degree angle.
9. Continue pushing until the spreader slide comes off the end, still maintaining the angle, as shown in the figure on the next page. The resulting smear should be approximately $1\frac{1}{2}$ inches long, preferably with a margin of

FIGURE Procedure 48-4 Step 8 When the drop covers most of the spreader slide edge, push the spreader slide back toward the unfrosted end of the smear slide.

empty slide on all sides. The smear should be thicker on the frosted end of the slide.

10. Properly label the slide, allow it to dry, and follow the manufacturer's directions for staining it for the required tests.

FIGURE Procedure 48-4 Step 9 Push the spreader slide off the end of the smear slide, maintaining a 30- to 35-degree angle. The smear should be thicker on the frosted end of the slide.

11. Properly dispose of used supplies and disinfect the work area.
12. Remove the gloves and wash your hands.

PROCEDURE 48-5 Measuring Hematocrit Percentage After Centrifuge

WORK // DOC

Procedure Goal: To identify the percentage of a blood specimen represented by RBCs after the specimen has been spun in a centrifuge

OSHA Guidelines:

Materials: Blood specimen (from either a capillary puncture or a specimen tube containing anticoagulated blood), microhematocrit tube, sealant tray containing sealing clay, centrifuge, hematocrit gauge, wooden applicator sticks, gauze squares, patient chart/progress note, and laboratory report form

Method:

1. Wash your hands and don exam gloves.
 2. If using blood from a capillary puncture, follow the steps in Procedure 48-3 to express a drop of blood from the patient's finger. If using a venous blood specimen, check the specimen for proper labeling, carefully uncup the specimen tube, and use wooden applicator sticks to remove any coagulated blood from the inside rim of the tube. Alternately, use a safety transfer device if available.
- RATIONALE:** *The safety device decreases the likelihood of exposure to bloodborne pathogens.*

3. Touch the tip of one of the microhematocrit tubes to the blood specimen, as shown in the figure below. The tube will take up the correct amount through capillary action.

FIGURE Procedure 48-5 Step 3 Touch the tip of one of the microhematocrit tubes to the blood specimen.

© McGraw-Hill Education

4. Pull the microhematocrit tube away from the specimen, holding it carefully to prevent spillage. Wipe the outside of the microhematocrit tube with a gauze square.
- RATIONALE:** *To remove excess blood so that it is not splashed or splattered on the inside of the centrifuge.*
5. Hold the microhematocrit tube in one hand and press the other end of the tube gently into the clay in the sealant tray. You may need to place a gloved finger over the other end of the tube to prevent leakage. The clay plug must completely seal the end of the tube.

RATIONALE: The tube must be sealed to prevent the specimen from being forced out of the tube during the spinning process.

FIGURE Procedure 48-5 Step 5 Press the end of the tube into the clay in the sealant tray.

© McGraw-Hill Education

6. Repeat the process to fill another microhematocrit tube. Tubes must be processed in pairs.

RATIONALE: To maintain a balance in the centrifuge.

7. Place the tubes in the centrifuge, with the sealed ends pointing outward. If you are processing more than one specimen, record the position identification number in the patient's chart to track the specimen.

FIGURE Procedure 48-5 Step 7 Be sure to place the tubes in the centrifuge so that the sealed ends are pointing outward or downward.

© McGraw-Hill Education

8. Seal the centrifuge chamber.
9. Run the centrifuge for the required time, usually between 3 and 5 minutes. Allow the centrifuge to come to a complete stop before unsealing it.
10. Determine the hematocrit percentage by comparing the column of packed RBCs in the microhematocrit tubes with the hematocrit gauge, as shown in the figure in the right-hand column. Position each tube so that the boundary between sealing clay and RBCs is at zero on the gauge. Some centrifuges are equipped with gauges, but others require separate handheld gauges.

(a)

(b)

FIGURE Procedure 48-5 Step 10 Read the column of packed red blood cells using the microhematocrit gauge (a) or reader (b) to determine the hematocrit percentage.

(a) © Total Care Programming, Inc.; (b) © McGraw-Hill Education

11. Record the percentage value on the gauge that corresponds to the top of the column of RBCs for each tube. Compare the two results. They should not vary by more than 2%. If you record a greater variance, at least one of the tubes was filled incorrectly and you must repeat the test.
12. Calculate the average result by adding the two tube figures and dividing that number by 2.
13. Properly dispose of used supplies and clean and disinfect the equipment and the area.
14. Remove the gloves and wash your hands.
15. Record the test result in the patient's chart/progress note and/or the laboratory report form as required. Be sure to identify abnormal results.

PROCEDURE 48-6 Measuring Blood Glucose Using a Handheld Glucometer

WORK // DOC

Procedure Goal: To measure the amount of glucose present in a blood specimen

OSHA Guidelines:

Materials: Safety-engineered capillary puncture device (automatic puncture device or other safety lancet), antiseptic and cotton balls or antiseptic wipes, sterile gauze squares, sterile adhesive bandages, handheld glucometer, reagent strips appropriate for the device, patient's chart/progress note, and quality control log

Method:

1. Wash your hands and don exam gloves.
2. Review the manufacturer's instructions for the specific device used.
3. Check the expiration date on the reagent strips.
RATIONALE: To make sure they are not outdated.

4. Code the meter to the reagent strips if required.
RATIONALE: Some machines will need to be coded to account for small differences in the strips that occur during the manufacturing process.
5. Turn the device on according to the manufacturer's instructions.
